The Improvement of a High Alloy Austenitic Chromium-Nickel Steel by Precipitation Hardening. (Die Vergütung eines hochlegierten austenitischen Chrom-Nickel- Stahls durch Ausscheidungshärtung.) E. Greulich. *Archiv für Eisenhüttenwesen*, Vol. 5, Dec. 1931, pages 323-330.

Report from the Research Laboratory of the Isolation A.-G., Mannheim. 9 references. After briefly reviewing the literature on precipitation hardening in various alloys, the author presents the results of his own investigations which were carried out on 6 Cr-Ni steels of the following ranges of composition: C: 0.22-0.51%; Si: 0.06-0.12%; Mn: 1.40-2.30%; P: 0.018-0.037%; S: 0.014-0.032%; Cr: 9.60-11.48%; Ni: 33.53-36.05%. The mechanical properties were determined after various treatments which caused precipitation of carbides. For hardness tests, cubic specimens 20 mm.^{2} of the above steels were annealed at 1200° C. for 6 hrs., water quenched and aged at temperatures from 400° to 1000° C. for from ½ hr. to 100 hrs. The hardness is essentially increased at aging temperatures between 650° to 800° C., with the largest increase shown at temperatures between 650° to 700° C. amounting to about 90% of the original hardness. To attain maximum hardness aging times between 24 hrs. and 100 hrs. are necessary at 650° C, but at 700° C. the maximum values are obtained at 24 hrs. The increase of hardness is accelerated at higher temperatures but the possible increase of hardness decreases, so that it amounts to only 65% at 750° C. and to 50% at 800° C. The other mechanical properties also were determined on test bars, annealed at 1000° C., 1050° C., 1100° C., 1150° C. and 1200° C. and aged at 700°, 750° and 800 C. for various times. In quenching from 1200° C. and aging at 700° C., the yield point is increased by about 90% to 52.3 kg./mm.^{2}; the tensile strength by about 20% to 80 kg./mm. These maximum values were attained after an 8 hr. aging. Elongation and notch toughness are correspondingly decreased, maximum, about 50%. Whereas after an 8 hr. aging, elongation and reduction of area amount to 19% and 47% respectively, the corresponding values after 100 hrs. aging are 13% and 36%, respectively. The cooling velocity must be rather rapid for air cooled specimens show but slight effects of improvement and furnace cooled specimens, none at all. The C content of the steel is of great importance. The effect of improvement is remarkable even at 0.2% C., reaches its maximum at 0.3%, but decreases again at 0.4%. The properties of improved specimens were also studied at elevated temperatures. The result is that up to 500° C., yield point and tensile strength are essentially higher than in non-improved state. The author, therefore, draws the conclusion that the creep limit will also be found at higher temperatures and that the velocity of creep is lowered. The solubility in concentrated HCl is increased by improving by about 400%. This increased solubility does not become apparent unless the specimens are aged for a very long time. The carbide precipitations are clearly shown in the aged specimens, and it could be proved that the number of the carbides precipitated has to surpass a certain limit to bring about an essential improvement of the mechanical properties. It is, furthermore, shown that the arrangement of the carbides upon planes of slippage is of importance. In comparing the results on the number of carbide particles precipitated with those of the previous investigation by E. Greulich & G. Bedeschl. (*Archiv für Eisenhüttenwesen*, Vol. 3, 1929, pages 359-363), it is found that the decrease of the number of the precipitated carbide particles with increasing drawing temperature is slower when cold work does not precede the drawing. From this fact Greulich concludes that the improvement itself is also accelerated by preceding cold work.
GN (10f)

Hardening Phenomena of the Iron-Boron-Alloys with Particular Reference to Precipitation Hardening. (Ueber Härtungserscheinungen der Eisen-Bor-Legierungen mit besonderer Berücksichtigung der Ausscheidungshärtung.) R. Wasmuht. *Archiv für Eisenhüttenwesen*, Vol. 5, Nov. 1931, pages 261-266; *Krupp'sche Monatshefte*, Vol. 12, Nov. 1931, page 273.

The system Fe-B belongs to a group of systems having a narrowed γ-field. The solubility of B in γ-iron varies between 0.10 and 0.15% B according to temperature. The A_3 point is raised by B with simultaneous lowering of A_4. A series of tests is described which showed an increase in Brinell hardness from 140 to 330 when the content of B increased from 0 to 2.5%. By addition of Mn and heat treatment higher values could be obtained; all Mn-B steels showed after a subsequent annealing a pronounced segregation hardening. Cr-Ni-B steels with not more than 0.4% B show an increase of tensile strength and elastic limit. Fe-B alloys show, according to the degree of alloying, both quenching hardness and tempering hardness. For details of the tests the paper must be referred to.
GN+Ha (10f)

Age-hardening of Alloys, Especially on the Basis of Investigations of Light Metals and of Beryllium Alloys (Vergütung von Legierungen, insbesondere auf Grund der Untersuchungen an Leichtmetallen und an Legierungen des Berylliums). G. Masing. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.-Sept. 1931, pages 414-428.

The refining phenomena of alloys occur only if the alloy can be obtained by quenching from high temperatures in the state of homogeneous crystals which disintegrate at low temperatures. These conditions are thoroughly investigated, using as a basis the diagrams of state of binary and ternary alloys and the change of technological properties in refining. Dependence on temperature conditions is discussed. Examination with X-rays produced the most fruitful results in the determination of the changes of structure in refining.

Bronze-Welded Casings Overcome Well Problems. *Water Works Engineering*, Vol. 84, Dec. 30, 1931, page 1784.

Description of bronze welding of cast iron pipe. The bronze welded joint insures full thickness of the pipe wall and resists ordinary attack of water. CBJ (11c)

A Few Practical Communications from the Field of Acetylen-Welding. (Einige praktische Mitteilungen aus dem Azetylenschweiss Gebiete.) H. Schuhmacher. *Autogene Metallbearbeitung*, Vol. 24, Dec. 15, 1931, pages 367-372.

Methods of welding pipe lines for steam, gas and water in domestic and industrial installations are discussed and illustrated. Ha (11c)

Improvements in Automatic Electric Arc Welding. *Welder*, Vol. 3, Sept. 1931, pages 21-24.

The advantages of automatic arc-welding are given as follows: increased speed due to the use of higher current values than can be employed by hand welding and, consequently, better penetration and a smaller number of passes for welding any given thickness of material; neater appearance and sounder weld due to elimination of the human element. In England, 95% of the welding is carried on with flux-covered electrodes. 2 processes (Metro-Vick and the Murex Welding Process, Ltd.) are described in detail and the difficulties in the way of employing flux-covered electrodes are indicated. Ha (11c)

A Severe Test for "Cresta" Electrodes. *Welder*, Vol. 3, Sept. 1931, pages 31-32.

2 semicircular mild steel plates of 5/16 in. were welded together to form a disk of 9 in. diameter and then, after heating to flanging heat, a cup-shaped vessel was formed by driving through a ball 4 in. in diameter under a steam hammer. After this, it was reheated and swaged down to a diameter of 3 in. under a steam hammer. After reheating again, it was flanged to a diameter of 5 in. The weld remained intact during the whole process. Ha (11c)

Steel Founders Hear Talk on Welding of Rolled and Cast Steel Parts. *Steel Founder*, Vol. 2, Jan.-Feb. 1932, pages 3-5.

In a discussion the American Society for Testing Materials and American Railways Association specifications are endorsed by the Steel Founders' Society of America. Ha (11c)

Arc and Resistance Welding of Monel Metal. (Ueber das autogene und elektrische Schweissen von Monel-Metall.) F. Schüppel & W. Kästner. *Zeitschrift für Metallkunde*, Vol. 23, Oct. 1931, pages 286-291.

Physical test data (breaking strength, tensile strength, reduction in area, and elongation) are given on sections of Monel metal welded by the arc and resistance methods. These show that Monel may be satisfactorily welded without the use of flux powders or pastes by electric resistance welding and arc welding. Electric butt seam welding is not successful. The finished welds resist corrosive attack successfully of bleaching solutions, soap baths, hot water, caustic soda solutions, dyes such as sulphur black and colored and vat dyes,—to a limited extent in hypochlorite lye and formic acid, and poorly in solutions of copper mordants. RFM (11c)

Acceptance of Watergas Lap-welded Boiler Drums and Shell Rings. (Abnahme wassergas-überlapptgeschweisster Kesseltrommeln und Schüsse.) E. Rüter. *Die Wärme*, Vol. 54, Apr. 25, 1931, pages 312-316.

The paper before the Zentralverband der Preussischen Dampfkessel Überwachungsvereine, 1931, takes the following steps: manufacture of water gas lap-welded shell rings and drums, question of weldability, acceptance in accordance with the regulations of the Verein der Grosskesselbesitzer, supplementary testing methods such as tensile and bend tests, serve as inspection of the semi-finished gas-welded seams. EF (11c)

New Code for Fusion Welding likely to be Misapplied. F. G. Sherbondy. *Steel*, Vol. 89, Nov. 30, 1931, pages 35-36.

Some of the specifications in the new code give rise to misinterpretation; the difficulties of classification are discussed and the coöperation of all companies urged to take into account the new developments in this comparatively new field. Ha (11c)

The Arcatom-Welding Process; Electric Arc-Protective Gas-Welding in Dissociated Hydrogen Gas According to Langmuir. (Das Arcatom-Schweissverfahren; Lichtbogen-Schutzgasschweissung in dissoziiertem Wasserstoffgas nach Langmuir.) S. Sandelowsky. *Zeitschrift Verein Deutscher Ingenieure*, Vol. 75, Oct. 31, 1931, pages 1361-1364.

After a thorough discussion of the principles of the process, the metallurgical conditions of the weld and its tests and the fields of application, the advantages of this method are summarized; the structure is finely crystalline, the strength of welds is hardly inferior to that of non-welded sheets. The economy is good for thin sheets, 1 to 6 mm. Most steels and non-ferrous metals can be welded by this process. Ha (11c)

The Permissible Loading of Arc-Welded Seams. (Die zulässige Beanspruchung von lichtbogengeschweissten Nähten.) S. Sandelowsky. *Maschinenbau*, Vol. 10, Mar. 19, 1931, pages 197-199.

The article discusses the importance of calculating the strength of the weld in machines, the relative costs of 1 kg. of welding rod, the lowest stress values for seams, permissible stresses, numerical values and the influence of stresses. MAB (11c)

The Oxy-Acetylene Welding of Copper and Aluminum and Some of their Alloys. Francis A. Westbrook. *Metal Industry*, New York, Vol. 29, Oct. 1931, pages 424-425; Nov. 1931, pages 469-470.

The welding of brasses, bronzes and Monel metal is discussed. Cu completely deoxidized with Si can be readily welded. Welding rod of commercially pure Al and a good Al flux are requisites for welding Al. For strong Al alloys, simple joints must be made using welding rods of 5% Si or of same composition as the base metal, in which case allowance for contraction must be made. After welding it is advisable to heat treat at 890-940° F. and water quench. PRK (11c)

The Rigidness of Rails when their Joints are welded (Die Steifheit der Eisenbahngleise mit geschweissten Schienenstoessen). W. Wildt. *Zeitschrift des Oesterreichischen Ingenieur- und Architekten Vereins*, Vol. 83, Apr. 30, 1931, pages 89-93.

The advantages gained by the welding of rails are pointed out and the precautions which must be borne in mind on welding rails are given. The warping due to temperature influences are calculated for different mounting profiles of the tracks. 6 illustrations. EF (11c)

Welding of Nickel (Das Schweissen von Nickel). H. Obermüller. *Apparatebau*, Vol. 44, Jan. 22, 1932, pages 12-13.

Outline of the welding practice of nickel. GN (11c)

Inspection Service for Welded Structures Seen as Need. H. L. Whittemore (Bur. of Standards). *Steel*, Vol. 88, Feb. 1931, page 44.

Points out the urgent need in the welding industry for an authoritative consulting service to qualify welders, pass on welding methods, criticize the suitability of structural design, inspect, test and approve of work under way, and certify to the reliability of the completed job. JN (11c)

The Efficiency of Welded Joints. More recent View-points regarding their Valuation and Calculation for the Construction of Boilers and Tanks. (Der Wirkungsgrad von Schweissverbindungen. Neuere Gesichtspunkte für ihre Bewertung und Berechnung im Kessel- und- Behälterbau.) K. Vigener & F. W. Rüdel. *Die Wärme*, Vol. 54, Nov. 28, 1931, pages 875-888; Dec. 5, 1931, pages 901-908.

The article subdivides the topic as follows: Calculation of the wall thickness of cylindrical boiler drums. The notion "seam efficiency" and its significance specified by the authoritative regulations. "Method efficiency" (changes in physicals, later occurrence of internal stresses) and "shape efficiency" (depending on the kind or shape of the joining) a) welded joints, b) riveted joints. New proposal on the method efficiency for welded joints and determination of the "partial efficiency." Shape efficiency of welded joints and their determination by a) theoretical derivations b) tensile tests. Tables collecting data on shape efficiencies for longitudinal and circumferential seams. Influence exerted by the location of the seam. Summary: limiting conditions for the efficiency degrees. EF (11c)

Testing of Alumino-Thermally Welded Rail Joints in Soviet Russia. (Prüfung von aluminothermischen Schweissungen bei Schienenstössen in U.d.S.S.R.) B. Tchistjakow. *Organ für die Fortschritte des Eisenbahnwesens*, Vol. 86, Aug. 15, 1931, pages 352-354.

62 welded rail joints were submitted to static and dynamic testing respectively. The experiments under the auspices of the Russian Government refer to (a) a "combined welding method" and (b) to butt welding. Tests concerning the bending and ultimate load determination yielded the following data:

	bending	ultimate load
(a)	37 500 kg.	64 kg/mm²
(b)	33 200 kg.	57 kg/mm²

The experience gained on the application of the combined welding method and on butt welding are detailed. EF (11c)

A Personal History of the Arc-Welding Process. J. C. Lincoln. *Boiler Maker*, Vol. 31, Oct. 1931, pages 265-267.

An historical sketch of the development of arc welding, up to its latest improvements, as illustrated by the Lincoln Electric Company. Ha (11c)

Impressions in the Field of Welding Technique in the United States of America (Eindrücke auf dem Gebiete der Schweisstechnik aus den Vereinigten Staaten von Amerika). H. Lottmann. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Oct. 10, 1931, pages 1265-1269.

The latest developments, particularly in electric arc welding, both manual and automatic, are described and the details of welds for tanks, boilers and in shipbuilding are discussed. Ha (11c)

The Valuation of Welding with Reference to the Legal Enactments on the Manufacture of Boilers. (Bewertung des Schweissens in den für die Herstellung von Dampfkesseln gegebenen gesetzlichen Bestimmungen.) K. VIGENER. *Die Wärme*, Vol. 54, June 27, 1931, pages 481-492.
Historical review of the government's enactments. Specifications for welding and riveting. Comparative valuation of both methods of joining. Practical examples of actual welding performances. Testing methods for welded seams. Résumé of the advances of welding technique. Regulations in foreign countries and future trend. A paper before the combined meeting of 3 German engineering associations. EF (11c)

Electric Arc Welding in Mines. CARL LEE. *Electrical World*, Vol. 98, Nov. 28, 1931, pages 953-954.
Electric arc welding is effecting substantial savings in the salvage of worn or broken parts in a majority of operating mines. A motor-generator set is cheapest for more than 85 hrs.' welding time/yr. Tires are also built up of weld metal. WHB (11c)

Production Welding of Auto-Body Stampings. J. W. MEADOWCROFT & JAMES J. PAUGH. *Metal Stampings*, Vol. 4, Dec. 1931, pages 953-956.
Modern stamping designs and fabrication methods of welding parts of the automobile body are discussed. Ha (11c)

Fire-welded Seams on Headers. (Feuergeschweisste Nähte an Wasserkammern.) H. TÜRKE. *Die Wärme*, Vol. 54, Nov. 28, 1931, pages 890-892.
The paper reports on the difficulties which were encountered with the defective welded joints on the flanged end plates of the front headers of two 300 $m.^2$ boilers. The headers are electric-welded and strengthened by Höhn lashes and the remaining fire-welded seams are strengthened by welded-on bracings. The single steps of the reconstruction work are described. EF (11c)

The Structural Steel Welding Committee's Report. FRANK P. MCKIBBEN. *Welding*, Vol. 2, Dec. 1931, pages 808-810.
The author refers to this report as a classic of greatest value to engineering and summarizes it as follows: (1) Permissible unit stresses, namely 11,300 $lb./in.^2$ shear, 13,000 tension, 15,000 compression, specified by the American Welding Society for structures bearing quiescent loads, are approved. (2) Qualified welders of commercial joints may be expected to produce strengths within 12% of a general average for a given type of joint. (3) The types of joints investigated are divided into 2 classes, depending upon the degree of symmetry or eccentricity in the welds. TEJ (11c)

Welding of Acid Resistant Steels. (Das Schweissen von säurefestem Stahl.) E. R. THEWS. *Die Metallbörse*, Vol. 21, Jan. 24, 1931, pages 149-150.
The difficulties encountered in the welding of stainless steels are pointed out and the successful welding performance is fully discussed with reference to (a) the arc welding process and (b) oxy-acetylene welding. EF (11c)

The Practical Application of the Arcogen Welding Method with Special Reference to its Suitability to Welding of the Technically Important Materials. (Die praktische Anwendung des Arcogen-Schweissverfahrens unter besonderer Brücksichtigung seiner Geeignetheit für das Schweissen der technische wichtigen Werkstoffe.) H. MUENTER. *Die Schmelzschweissung*, Vol. 10, Dec. 1932, pages 279-284.
The principle of the arcogen method is briefly explained. The method of its application for and the results on steels of low carbon up to 50 mm. thickness is described, obtained values of tensile strength, elongation and notch-toughness are given, also metallographic results of cold-bending tests. Ha (11c)

Welding of Stainless and Corrosion Resistant Alloys. W. B. MILLER (Union Carbide & Carbon Lab.) *Metal Progress*, Vol. 20, Dec. 1931, pages 68-72.
General technique of welding these alloys is described. Neutral flame, flux which will dissolve oxides of Fe and Cr and show suitable fluidity, desirability of preheating, care of the cooling weld to avoid straining in its tender temperature range and cleanliness are emphasized. Special precautions with individual alloys are discussed under 6 headings, cutlery stainless, low carbon stainless, high chrome iron, 18-8 type, high Cr-Ni-Si alloys and heat resistant alloys. WLC (11c)

Failures during the Welding of Overhead Cranes (Nahtrisse während der Kranschweissung). K. MELCHER. *Zeitschrift des Oesterreichischen Ingenieur- und Architekten Vereins*, Vol. 83, Sept. 18, 1931, pages 291-292.
The writer reports at length how to overcome the shrinkage difficulties experienced during the welding of a 10 ton over-head crane. EF (11c)

Erection of Yale Welded Buildings. D. E. KING. *Welding*, Vol. 2, Nov. 1931, pages 745-750.
Paper presented before the October meeting of the Pittsburgh Section of the American Welding Society. Details of construction of the Yale University group of welded buildings. Includes estimating, detailing and fabrication, erection, the field force, inspection, general information, suggestions, comparison of welds and rivets and advantages credited to welding. TEJ (11c)

Opportunities for Welding-Trained Men in Metal Working Trades. S. LEWIS LAND. *Heating & Ventilating*, Vol. 29, Jan. 1932, pages 43-45.
Welding insures lower first costs and maintenance costs. Data obtained from a welded pipe installation in one of the buildings of the Bureau of Standards in Washington shows a considerable saving in weight and bulk, in some cases as much as 100%. WAT (11c)

Determining Factors for the Application of Oxy-Acetylene Welding in Welding-On of Flanges (Massgebende Gesichtspunkte für die Anwendung der Azetylenschweissung beim Aufschweissen von Flanschen). HANS KRUSE. *Autogene Metallbearbeitung*, Vol. 24, Oct. 15, 1931, pages 307-310.
For medium and high-pressure pipe lines, oxy-acetylene welding has given excellent results in the welding of flanges and branches. A few examples are illustrated. Ha (11c)

Welding of Steel Girders. (Schweissen von Blechträgern.) HANS KRUSE. *Autogene Metallbearbeitung*, Vol. 25, Jan. 15, 1932, pages 25-30.
The author gives examples for welded girders made up of T-steels and flat plates and points out the advantages of this method over riveting; prerequisite for successful construction is careful design which must take into account the particularities of welding. The calculation of an example is carried out in detail, and tests made to verify the design are described. Ha (11c)

Boiler Repair Welding. (Dampfkessel-Reparatur-Schweissungen.) J. KREFFT. *Die Wärme*, Vol. 54, Apr. 4, 1931, pages 259-260.
The author summarizes his paper read before the Verband für autogene Metallbearbeitung, Braunschweig, 1931, which discusses some examples of boiler repair work performed by welding. EF (11c)

Typical Example of a Difficult Cast-Iron Welding. (Schulbeispiel einer schwierigen Gusseisen-Warmschweissung.) KOHRS. *Die Schmelzschweissung*, Vol. 11, Jan. 1932, page 4.
The broken driving block of a 20 m. turn-table was successfully repaired by welding; the parts were first heated slowly to 450° C. and annealed after welding. Ha (11c)

Distribution of Tension in Welded Joints with Special Regard to Boilers. (Spannungsverteilung in Schweissverbindungen unter besonderer Berücksichtigung des Kesselbaues.) KOCHENDOERFER. *Autogene Metallbearbeitung*, Vol. 25, Jan. 1, 1932, pages 5-12.
The distribution of tension in butt-welds was determined by means of the laminar flow pictures of Hele-Shaw. A quantitative evaluation of the pictures is, however, not possible, it shows merely the danger spots of a joint. The actual course of the tensions can be determined by elastic-optic methods, from which then the most favorable profile of a butt-weld can be theoretically developed. The procedure is described and photographs of flow pictures reproduced. Ha (11c)

Scarfing Process is Effective in Eliminating Defects. J. D. KNOX. *Steel*, Vol. 88, March 19, 1931, pages 36-38.
A method of removing seams, scales, scratches, etc., from the surface of billets, slabs or other semi-finished shapes before the stock runs through the finishing mills, by means of scarfing torches similar to ordinary cutting torches is described. Ha (11c)

Lead Welding. OWEN C. JONES (Linde Air Products Co.). *Journal American Welding Society*, Vol. 10, Nov. 1931, pages 41-42.
The author outlines the general procedure for oxy-acetylene welding of Pb and describes a particular application of this process in the manufacture of lead lined steel storage tanks for H_2SO_4. TEJ (11c)

Repair of a Pressure Tank Lined with Aluminum. (Reparatur eines mit Aluminium ausgekleideten Druckgefässes.) W. JOHAG. *Autogene Metallbearbeitung*, Vol. 24, Dec. 1, 1931, pages 355-356.
Description of procedure. Ha (11c)

How Fast Does the Student Welder Learn? JAMES R. GRIFFITH (Oregon State College). *Welding*, Vol. 2, Dec. 1931, pages 804-807.
An experiment with learning curves of student gas welders in which the author attempts to establish an index by which one could anticipate an individual's ability to learn welding. TEJ (11c)

Electric Welding—Present and Future. C. A. HADLEY. *Welding Journal*, Vol. 28, Nov. 1931, pages 341-343; Dec. 1931, pages 374-375.
First installment of a paper read before the members of the Birmingham Electric Club, Nov. 20, 1931. A general review of arc and resistance welding applications. Several resistance welding machines are described. TEJ (11c)

Welding of Pressure Vessels is Winning Approval. J. C. HODGE (Babcock & Wilcox Co.). *Steel*, Vol. 88, Jan. 15, 1931, pages 44, 46.
During the past year, the Boiler Code Committee of the American Society of Mechanical Engineers has proposed tentative codes for the testing of fusion welded steam boiler drums and unfired pressure vessels. These tests include examination of representative test specimens, X-ray examination of the weld and hydrostatic testing. The U. S. Navy has accepted the use of welded construction in the fabrication of drums for 24 boilers now being built. Tests on 2 welded steel shells are described and the use of the X-ray equipment is illustrated. JN (11c)

An Alternating-Current Arc Welder. J. B. GIBB. *Electric Journal*, Vol. 28, Dec. 1931, pages 665-667.
The new type welder with a high-frequency oscillator removes the danger in a.c. welding of dangerously high overcircuit voltage, an unstable arc and the difficulty of using small currents. The new outfit consists of a welding transformer with means for adjusting the current by small steps and an oscillator which makes the arc as easy to handle as a d.c. arc. Characteristics are: lightness, cheapness, convenience, safety, ease of operation and adaptability. WHB (11c)

Electric Welding Saves 30 Per Cent of Job Cost. C. L. IPSEN. *Electrical World*, Vol. 98, Nov. 28, 1931, page 966.
A test, on a considerable scale, of electric welding and casting showed a saving of 30% of the cost of the cast job. WHB (11c)

The Strength of Frontal and Lateral Welds. E. HOEHN. *Engineering*, Vol. 132, July 24, 1931, pages 115-118.
Translated from a report to the Swiss Boiler Owners' Association. LFM (11c)

The Shielded Arc Process. C. J. HOLSLAG. *Industry & Welding*, Vol. 3, Jan. 1932, pages 21-24.
The process consists of covering the electrode so as to shield the arc and provide a refining atmosphere and in addition to the speed and refined metal advantages gained by this process, layer annealing is used. The procedure for welding V-cuts and the electrodes, voltage and current required for different thicknesses of the weld are tabulated. Ha (11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

The Stevens Open Hearth Furnace. THOMAS G. KUS. *Proceedings Engineers' Society of Western Pennsylvania*, Vol. 47, Oct. 1931, pages 391-404.

The Stevens open hearth furnace was primarily designed to establish and maintain, within the furnace, conditions that will promote more uniform metallurgical reactions; conditions that will reduce loss of metal and thereby result in greater yield; and conditions that will reduce inclusions, and produce better metal. The purpose was also to attain the highest thermal efficiency by better combustion and maximum heat recovery and to speed up and, thereby, increase the tonnage output of a given size unit. The Stevens furnace, both basic and acid, has been in continuous service long enough to establish the principal facts of these outstanding advantages. Patents have been granted Arthur L. Stevens for his methods of construction and operation, and demonstrations in the past 4 years have prompted others to imitate the method in part. In the discussion a fuel consumption of 3,500,000 B.t.u./ton of product was quoted as a monthly figure for one unit. WAT (12a)

The Production of Synthetic Cast Iron in the Electric Furnace (Die Erzeugung von synthetischem Gusseisen im elektrischen Ofen). R. B. DUPUIS. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, page 867.

A brief review of the historical development of the production of cast iron from steel scrap and C. This manner of manufacture has gained a great importance in many countries, especially in Italy. Ha (12a)

The Manganese Reduction During the Steel Melting Process (Zur Frage der Manganreduktion bei der Stahlherstellung). ED. MAURER & W. BISCHOF (Bergakademie Freiberg). *Zeitschrift für physikaische Chemie*, Abt. A, Vol. 157, Nov. 1931, pages 285-309.

Based on their previous equilibria investigations the authors consider quantitatively the factors dominating the distribution of manganese between the steel and the slag in the basic open-hearth process. The influence of the input of Mn, the amount of slag, the slag analysis and the temperature are successively taken up. Formulae covering the Mn-balance are derived. The theoretical deductions made are in very satisfactory agreement with data collected in the plant. The results are presented in 14 diagrams. 7 references. 3 tables. EF (12a)

Physicochemistry of the Reactions Between Steel Bath and Slag (Physikalisch-chemische Unterlagen zur Beurteilung der Beziehungen zwischen Stahlbad und Schlacke). G. TAMMANN. *Archiv für Eisenhüttenwesen*, Vol. 5, Aug. 1931, pages 71-74.

Report 212 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The author shows that the classification of the electro-chemical potentials as it holds with regard to aqueous solution of metals also holds in general with regard to liquid melts of the chlorides and silicates of metals. Those metals which are nobler than iron migrate from the slag to the steel bath when they are not yet contained in the steel bath, and metals which are less noble than iron migrate from the steel bath into the slag. According to this rule, the metals of the alkalies, the alkaline earths migrate from the steel bath into the slag or they remain in the slag if they are already present in the slag. The above rules as to the direction of the reaction, however, can only be applied when the metal in consideration in the silicate melts is present as cation. The paper then deals with the equilibria between the binary mixtures of metals and liquid mixtures of its salts and shows that there exist simple rules about the quantitative distribution of alloying elements between steel bath and slag within the concentration range which is governed by the laws holding for diluted solutions. GN (12a)

The Distribution of the Alloying Elements of Iron between Steel Bath and Slag During Steel Production (Die Verteilung der Eisenbegleiter zwischen Stahlbad und Schlacke bei der Stahlerzeugung). G. TAMMANN & W. OELSEN. *Archiv für Eisenhüttenwesen*, Vol. 5, Aug. 1931, pages 75-80.

Report 213 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The paper endeavors to deduce some simple empirical rules about the distribution of the admixtures of the steel between steel bath and slag. This has been done by critically reviewing the literature on the subject. The results are as follows: The distribution of Mn between steel bath and slag is governed by the simple law of mass action. With basic slags having the ratio of CaO to SiO_2 above 2, the equilibrium constant is independent of this quotient, but the equilibrium constant is decidedly affected by this quotient when the ratio of CaO to SiO_2 is below 2. According to the present known data, the equilibrium constant is not very much affected by the temperature. With basic melts, the distribution of Mn between bath and slag is in equilibrium only in the case the P reaction is also approximately in equilibrium. GN (12a)

Lime-Iron Oxide-Silica Slags (Über Kalk-Eisen-Silikatschlacken). E. J. KOHLMEYER & G. SITZ. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 429-435. 7 figures, 11 references.

The dissociation of Fe_2O_3 in these slags was studied by magnetic methods. The melting points of the slags are shown in ternary diagrams. HWG (12a)

Fundamental and Applied Research on the Physical Chemistry of Steel Making. C. H. HERTY, JR. *Blast Furnace & Steel Plant*, Vol. 19, Feb. 1931, pages 277-278.

Reproduction in part of *Report* No. 3054 of the *U. S. Bureau of Mines* on investigations of clean and dirty steels from various heats. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 42. Ha (12a)

Soda Ash as Desulphurizing Agent in the Foundry. *American Metal Market*, Vol. 38, Sept. 16, 1931, page 10.

Reprinted from Manchester Guardian. Desulphurizing by means of soda ash is both simple and inexpensive. Process can be applied at various stages in the manufacture of steel and iron and alloys with the regular routine followed. Reagents required are commercial powdered soda ash and ground limestone. Reduction of S content of the metal prevents cracking of steel castings and is also accompanied by definite improvement in the physical properties, together with almost complete elimination of non-metallic inclusions of sulphides, oxides, etc. Cost of manufacture is reduced because products can be made from pig iron and coke of higher S content and greater proportion of scrap metal. DTR (12a)

The Comparison of Different Fluxes for Magnesium Alloys. K. Endo. *Kinzoku no Kenkyu*, Japan, Jan. 1932, pages 24-30.

Mg and its alloys were melted with various fluxes and the effect of the latter was compared by measuring the electrical resistance, tensile strength and microscopic structure of metals obtained. The melting loss was also compared. The best result was obtained by using 3% of a flux consisting of 66 % $MgCl_2$ + 7 % MgF_2 + 23 % KCl + 4 % NaCl. The electric resistance of pure Mg was 3.983×10^{-6} ohm and the tensile strength 13.88 kg./mm². The tensile strength of electron A.Z.D. and Dow metal D was 19.8 and 19.6 kg./mm² respectively which is 1 to 3 kg. greater than the alloys treated with other fluxes. KT (12a)

The Bessemer Process and Its Product. R. S. McCaffery. *Yearbook American Iron & Steel Institute*, 1931, pages 351-386.

Includes discussion. The author surveys the present position of the Bessemer process in America. The change of conditions taking place for some years past has placed the process in a more favorable position than it occupied a few years ago. Bessemer steel has retained its place for those uses where it has always been superior and has replaced other steels in some of the newer applications. This improved position is due to larger Bessemer ore reserves than formerly, a more complete knowledge of metallurgical chemistry, the introduction of control methods and new equipment. Electrically-driven blowing equipment has been installed recently at one plant, each converter being provided with an individual motor-driven centrifugal blowing unit on an individual air line to the converter. Any blower can be connected with any converter with complete control from the blowing pulpit. The operator has a pressure gage, a volume meter, and a tachometer in addition to start, stop, and speed regulation buttons. Two charts are given of 2 soft steel blows, one blow maintaining constant pressure, after cold metal additions, and the other maintaining constant volume for the same time. Where constant pressure was maintained, the volume remained practically constant in the early part of the blow, but in the latter part the volume increased rapidly from 18,000 to 30,000 ft³/min., although the pressure remained the same. The volume at the end increased about 60%. The slope of the volume curve decreases and flattens out just before the turn down. In the case where the volume was kept constant, corresponding pressure decreases are shown. This variation of metal bath resistance to the blast is caused by changes in the viscosity of the bath because of changes of composition and temperature and also by the increase of weight of the bath due to the elimination of C toward the end of the blow. A chemical change in the molten metal bath can be noted almost instantaneously by means of the pressure gage, and a change in the rate at which oxygen is added can be made in a few seconds. The author draws attention to the fact that high air pressure does not mean high tonnage production and that a reduction in pressure may cause a very considerable decrease in blowing time and a decrease in blowing energy. A table is given showing the results obtained by increasing the number of tuyeres and decreasing the blast pressure. It is predicted that in the future the Bessemer converter will be operated on a predetermined cycle, with adjusted composition and initial temperature. The volume and pressure of the air blast will be maintained or varied as the blowing cycle chart indicates, the regulation being done by automatic control. The turn down will be done automatically either when the required air volume has been blown into the converter or by the carbon-flame drop, or one method may be used to check the other. The blown metal on the turn down will then be at the proper temperature, and it will contain the desired amount of Si and Mn to secure the proper softening reaction which will be completed during pouring. For other than soft steel blows, the turn down will be made automatically when the predetermined volume of air has been blown to obtain the specified C. The bath will contain the requisite Si and Mn which, being residual, will rapidly deoxidize the metal so that, on pouring, no additions need be made for this purpose. Ha (12a)

Reverberatory Melting of Tin and White Metal Scrap. (Flammofenschmelzen von Zinn-und Weissmetallrückständen.) E. T. Richards. *Die Metallbörse*, Vol. 21, Apr. 4, 1931, pages 627-628; Apr. 18, 1931, pages 726-727.

A critical discussion on the melting of tin and white metal scrap in blast furnaces and in reverberatory furnaces respectively is anticipated in the introduction and the practice and experiences with respect to the melting in the reverberatory furnace are fully discussed, whereby much regard is paid to the calculation of the furnace charge. EF (12a)

Fluxes for Melting and Remelting of Aluminum. (Flussmittel beim Schmelzen und Umschmelzen von Aluminium.) E. R. Thews. *Die Metallbörse*, Vol. 21, Jan. 24, 1931, pages 147-148; Jan. 31, 1931, pages 195-196.

The affinity of Al for oxygen and nitrogen, the low specific gravity of Al and its contaminations and the embedding tendency of aluminum oxide are considered and conclusions are drawn, aside from economical considerations, in regard to the peculiar metallurgical demands which must be fulfilled by fluxes indispensable for the melting of Al and Al-scrap. The different mixtures of fluxes and their properties are dealt with. EF (12a)

Silico-Spiegel Deoxidizing Agent Makes Uniformly Clean Steel. *Steel*, Vol. 88, Mar. 19, 1931, page 46.

Silico-spiegel is an alloy containing 7-8% Si and 25-30% Mn; its low melting point at about 1250° F. insures rapid deoxidation, and its composition leads to the formation of extremely large inclusions which rise rapidly at about 600 to 2400 in./min., thus providing a uniformly clean steel. Ha (12a)

Open-Hearth Operators Study Quality of Rimming Steel. *Steel*, Vol. 89, Dec. 14, 1931, page 38.

The best methods of obtaining high-grade steel from open hearth furnaces, distribution of heat and composition of metal in different levels within the bath, method of sample taking, velocity of refining action, are discussed with reference to an investigation of these questions by the Verein deutscher Eisenhüttenleute. Ha (12a)

On Dimensions and Operation of German Thomas Converters (Ueber Abmessung und Betriebsverhältnisse deutscher Thomaskonverter). *Stahl und Eisen*, Vol. 51, Sept. 3, 1931, pages 1105-1113; Sept. 10, 1931, pages 1136-1148.

This is the résumé of the results of a questionnaire sent to 17 German Thomas steel plants. General arrangement and operation are described; capacity, composition of charge, additions, amount of slag are tabulated. Figures on the consumption of refractory bricks and tar are given. All dimensions of the converters are given and compared. The last part deals with results of operation, the lining and life of converters and converter bottoms. GN (12a)

Vaporization of Magnesium in Vacuum (Verdampfung von Magnesium im Vakuum). W. Kaufmann & Ph. Siedler. *Elektrotechnische Zeitschrift*, Vol. 37, Aug.-Sept. 1931, pages 492-497; *Die Metallbörse*, Vol. 21, July 4, 1931, page 1255.

Mg evaporates very easily. The following 3 methods are possible: (1) distillation, (2) sublimation, (3) evaporation from a melt and condensation in a solid state. The range for distillation is above 650° C. and a pressure of 2 mm. Hg gage. Sublimation can be effected only at temperatures between 500° and 650° C. and pressures of 0.05-2 mm. Hg. The third method requires a definite temperature gradient between the place of evaporation and condensation and is an extreme case of distillation. The experimental arrangement is described and the precautions which are necessary to prevent foreign particles from being drawn along in the evaporation current are discussed. A purity of 99.99% Mg could be obtained. Pure Mg crystallizes easily in giant crystals in a manner similar to Cu. For a practical application, sublimation is the most promising process. EF+Ha (12a)

The Melting of Metals; Induction Furnace Design. Robert Hadfield. *Times*, London, Faraday Number, Sept. 21, 1931, page 18.

The principles of the modern coreless high frequency furnace are based on the Faraday discovery of induction. The construction and materials used are explained. The use of such furnaces covers a very wide range. Materials requiring 2000°-3000° C., for instance high class tool and magnet steels, heat-resisting and corrosion-resisting alloy steels, Ni-Cr alloys, tungsten-chromium-cobalt carbide, silica ware, precious and non-ferrous metals generally, can be melted. The melting is caused by the heat developed in the mass by the "Foucalt" eddy currents. The thermal efficiency of the energy exchange, that is the ratio of the heat utilized as sensible and latent heat in the metal to the heat equivalent of the power supplied at the bus bars, is from 50 to 60%. The cost of operation is discussed briefly as dependent on local conditions. Ha (12a)

Further Experiments on Oil-Hardening and Air-Hardening Cast Irons. J. E. Hurst. *Foundry Trade Journal*, Vol. 45, Dec. 3, 1931, pages 345-348.

The author records the results of further experiments on the heat-treatment of cast iron by air-hardening, and oil-hardening and tempering. The experimental work was conducted on the standard ring form specimens of the B.E.S.A. Air Board Specification 4K6. He finds that in suitable thin sections, plain unalloyed cast iron can be hardened by oil-quenching from suitable temperatures. Cr irons are capable of being similarly hardened, the presence of Ni being unnecessary to obtain the hardening effect. In suitable thin sections, plain Cr iron appears to give higher hardness values than Ni-Cr iron, and the hardening effect is more stable on tempering. In thicker sections, ordinary cast iron is not particularly susceptible to hardening by quenching in oil; Ni and Cr increase the hardening capacity, Ni having the effect of increasing the depth of penetration and the degree of hardness obtainable. A higher hardening temperature (920° C.) gives inferior results. The lowest possible quenching temperatures are to be desired. The development of air-hardening properties in Ni-Cr iron by the addition of Mn is discussed, and the effects of normalizing on the hardness and strength values have been shown to be of use in making the initial hardness more uniform and in slightly improving the strength properties. Quenching in molten salts at 150° C. results in a slightly higher strength value after hardening and prior to tempering and in a slightly lower hardness value. OWE (12a)

The Use of the Rotating Furnace for Melting Gray Iron (L'impiego dei forni girevoli per la rifusione della Ghisa). F. Giolitti. *La Metallurgia Italiana*, Vol. 23, Oct. 1931, pages 942-954.

The Stein-Brackelsberg and similar revolving powdered coal furnaces are favored over the cupola because of a lower pick-up of S and better control of composition. Suitable pulverized coal costs 130 lire/ton and, with a 5 ton furnace, not over 16% of the weight of the iron melted is required, while the cupola will take at least 13% of metallurgical coke costing 170 lire/ton, the fuel cost, under Italian conditions, thus being in favor of powdered coal. High test or pearlitic cast iron (steel added to the charge) is very satisfactorily made in the furnace, even when cast iron turnings are used. Tests cited show good properties. Use of the powdered coal furnace for mixing, superheating, degasifying and making additions to correct the composition of cupola metal is mentioned as a future possibility. Experiments on the use of the furnace for melting steel are encouraging. HWG (12a)

The Manufacture of Cast-Iron Molds for Steel Plants. (Die Herstellung von Stahlwerkskokillen.) R. Travaglini & R. Comina. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 6, 1931, page 867.

The composition, manufacture of molds and causes of waste are discussed. Castings from chill molds do not have a great mechanical strength but resist great fluctuations of temperature. C is present in an almost free state. The composition of such castings is 3.2-3.8% C, 1.5-3% Si, 0.7 Mn, 0.07% S. The charge is made up of 3/5 pig iron and 2/5 crushed mold-castings, not burnt. The molds are made by a centrifugal sand-molding machine; the core is made by a special device. Molds of 3 ton capacity can stand a little more than 300 castings. Waste castings are caused, generally, by cracks, corrosion and burns or erosions. A few suggestions are given for elimination of these causes. Ha (12b)

Experiences with Ingot Molds (Erfahrungen mit Stahlwerks-Blockkokillen). F. W. Morawa. *Stahl und Eisen,* Vol. 51, Oct. 1, 1931, pages 1221-1228; Oct. 8, 1931, pages 1256-1263.

Report 218 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The selection of ingot molds must be based, in the first place, on metallurgical considerations, i. e. the cross-section and weight of the ingots must be determined with due consideration of the production program of the individual steel mill. The molds must then be dimensioned and the material of the molds, either cast iron or steel molds, be so chosen that the highest degree of efficiency is guaranteed. In order to attain this end, the highest lifetime of the molds, with due regard to the continued production of sound steel ingots, is of prime importance. The experiences of the author favor the cast iron mold which, in spite of the shorter life in comparison with the steel mold, gives a sound ingot surface and which can also be handled more quickly than the steel mold. This experience does not prove that the cast iron mold is always better than the steel mold since there are also cases known where the steel mold proved to be superior. The life of cast iron molds was studied in applying various methods of cooling the molds. Some of the results are tabulated below:

Life of Molds	continually used	Molds used at every 2nd heat
Water dipped	128	...
Temporarily water dipped	160	209
Water sprayed	170	213
Air cooled	198	232

These results indicate that the best cooling would be a normal air cooling with 2 sets of molds, using them intermediately for subsequent heats. With this working procedure, lifetimes of 250 heats have been attained. The last chapter of the paper deals with the manufacturing of gray cast iron and steel molds with special American experimental molds composed of 2 materials, and with molds provided with special cooling devices. Finally the addition of alloying elements to cast iron is referred to. The prime alloying elements are: Cr, Ni and V. Ti has been used in England. GN (12b)

The Regular Reactions in the Solidification and Crystallization of Steel Ingots. (Die gesetzmässigen Vorgänge bei der Erstarrung und Kristallisation der Stahlblöcke). Bernhard Matuschka. *Archiv für das Eisenhüttenwesen,* Vol. 5, Jan. 1932, pages 335-354.

Report No. 220 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes tables of entire results, 36 illustrations, 24 references, and excellent discussions. After a review of the state of our knowledge on origin, character, and crystallization of ingots, a new method of investigation of C steels is described, by which the formerly unknown ingot structure may be seen by the so-called "blue-short fracture." Systematic tests of various casting and cooling conditions on the structure of a steel with 0.7% C. led to disclosure of disintegration reactions of ingot crystallization. For the primary crystal formation and the grain disintegration, the casting temperature and stopping time, or slow cooling and super-cooling conditions, especially in the critical temperature range, are decisive factors. Character of different types of steel ingot structure is given in complete detail and important distinctions between primary and secondary structure are defined. Comparisons of behavior of different steels may be made from the regularities observed in crystal structure of C steels. The great importance of formation of steel ingot structure is discussed with regard to heat treatment purposes and building up of finished materials. GN+DTR (12b)

Aluminum Castings in Permanent Metal Molds. V. Friedberg. *Vestnik Metallopromyschlennosti,* Vol. 9, Nov. 1929, pages 116-132.

The principles on which metallic molds for castings must be constructed are laid down. The shapes of the different sections of the molds and their methods of joining are discussed in detail. For gravity castings, special modifications are required for Al in view of its low density. To avoid the formation of cavities due to contraction on cooling, the lowest practicable pouring temperature must be used and the molds designed to facilitate gradual cooling. A series of mold designs for various purposes is discussed and a cast Fe of the composition graphitic C, 2.9%; combined C, 0.4%; Si, 1.5%; P, 0.5%; S, 0.05%; Mn, 0.9% is suggested. For casting under pressure, the most important factors are the accuracy of manufacture of the different component parts of the molds, and the provision of adequate vent holes to avoid bubble formation. The best material is Cr-V steel of composition: Cr, 2.1%; V, 0.35%; C, 0.4%; Mn, 0.65%; Si, 0.1%. Such a steel may give 5000-8000 castings, but for larger quantities W steels of the type C, 0.07%-0.88%; Si, 0-0.2%; Mn, 0-0.5%; W, 8-18%, Cr, 2.5-6.5%; Mg, 0-2.5% V, 0-1.50%; Mo, 0-6% is recommended. It is concluded that casting has not yet been perfected and considerable progress both in construction of molds and the composition of the alloys used for them is desirable. WHB (12b)

Fluidity of Cast Iron. N. N. Feigin. *Scientific Research Institute of Machine Building & Metal Treatment,* No. 7, 1931, Moscow, Russia.

The Curry method was used by the author to measure the running qualities of molten metals. Fluidity of molten metals is shown to be directly influenced by the pouring temperatures as well as other factors such as metal composition, etc. Metal may be hot and at the same time not fluid on account of the presence of gases, oxides or slag inclusions. The gases liberated during solidification as well as oxides or other impurities present in the molten metal prevent undercooling effects and therefore, affect fluidity. The melting point of iron oxides is high and due to this fact itself should have a certain effect on the fluidity of cast iron. A clean metal, therefore, possesses greater fluidity than dirty metal. 16 heats of cast iron, 3 heats of Sn-bronze and 2 heats of steel were made. It was found that Curry's method was not suitable for steel. Dry and green sand molds were employed. Hand molding was employed by the same molder throughout all the tests. Moisture of green sand was 5-7%, permeability 20-30, and compressive strength was 0.15-0.20 lbs./in.^{2} At each pouring temperature a dry sand mold was cast first and followed by pouring green sand mold. The temperature measurements were made by means of an optical pyrometer. This method, the author admits, was unsatisfactory for measuring the temperature of molten bronze. On the other hand, he states, a thermocouple inclosed in the protective tube gave too great a lag in readings. *Experiments with Cast Irons:* Although the same cupola charge was maintained during this investigation, the chemical analysis of different heats was quite different. The compositions of some of the most typical heats of cast iron used in this investigation are given in Table 1.

Element	%					
C	3.65	3.64	3.51	3.61	3.53	3.29
Si	2.57	2.67	2.96	2.92	3.12	2.48
Mn	1.20	1.35	1.84	0.85	1.05	0.93
P	0.13	0.70	0.60	0.41	0.33	0.50
S	0.11	0.099	0.053	0.086	0.063	0.11

5 dry and 5 green sand molds were cast from each heat. Diagrams of each heat were drawn. From the fluidity data of these individual heats, an average fluidity of various cast irons was calculated and average diagram was drawn.

Table 2—Fluidity of Cast Iron.

Pouring Temperatures °C	Average Lengths of Spirals Cast of Different Cast Irons Expressed in Number of Divisions of Curry's Spiral	
	Dry Sand Mold	Green Sand Mold
1340	19.50	17.25
1320	20.33	19.17
1310	20.00	15.50
1300	18.50	16.87
1290	18.75	17.25
1280	16.94	15.44
1270	14.50	11.25
1260	15.83	13.00
1250	15.66	12.60
1240	13.25	11.50
1230	13.62	10.57
1220	11.33	10.57
1200	10.50	8.92
1180	7.62	6.50
1170	4.83	4.50

The maximum heating temperature of the melt is, of course, of a great importance, but as the author pointed out, the same charge and same cupola procedure were used during this investigation. The rate with which an average fluidity of cast iron decreased with a temperature drop was more pronounced in the dry sand molds than in the green sand molds. It was emphasized by the author that different fluidities may be obtained for the cast irons of the same chemical composition depending upon the previous history of production. It was observed, for instance, that when Fe-Si was added to a white iron, the iron had a tendency to solidify as a white iron, in which case the fluidity of such an iron will be quite different from the iron of similar composition but prepared under different conditions. *Experiments with Tin-Bronze:* The composition of bronzes examined is given in Table No. 3.

Table 3—Composition of Bronzes.

Bronze No.	Cu	Sn	P	Pb
		Per Cent		
1	86.0	13.5	0.03	0.15
2	89.0	10.52	0.02	...
3	93.58	5.75	0.05	0.12

The maximum heating temperature in all cases was around 1170°C. The results of this test are presented in Table 4.

Table 4—Results of Fluidity Test with Tin-Bronze.

Bronze No.						
1	Pouring Temperature °C	1150	1120	1100	1075	1050
	Number of divisions spiral ran in dry sand	22.5	19.0	18.0	11.5	12.0
	Number of divisions spiral ran in green sand	15.0	13.0	11.0	...	...
2	Pouring Temperature, °C	1140	1130	1110	1060	
	Number of divisions spiral ran in dry sand	13.0	10.0	10.0	13.0	
	Number of divisions spiral ran in green sand	10.0	9.0	8.0	10.0	
3	Pouring Temperature, °C	1120	1110	1100	1090	
	Number of divisions spiral ran in dry sand	7	7	5	3	
	Number of division spiral ran in green sand	5	5	4	2	

In all cases a higher fluidity was obtained with the dry sand molds than with the green sand molds. The fluidity of bronze increased with an increase of tin content. AIK (12b)

Rolling (12c)

Repairing Rolls in Aluminum Rolling Mills by Hand Polishing (Die Herrichtung der Walzen in Aluminium-Walzwerken durch Handschleifen). R. J. Anderson. *Metallwirtschaft,* Vol. 10, Nov. 27, 1931, pages 897-898.

In rolling Al and Al alloys into sheet and strip it is necessary to keep the rolls polished, as any cracks, holes, dents or irregularities in the rolls produce a rough surface on the soft Al. In hot rolling, heat cracks often form and a deposit of Al powder from the material being rolled builds up on the rolls. This also causes a rough surface on the sheet. If the rolls are deeply cracked they must be removed and polished on machines, but small cracks and the deposit can be removed by polishing by hand. The deposit can be kept to a minimum by scrapers on the rolls. For hand polishing, a 3x4 in. piece of hard wood is used, tapered at one end to approximately the radius of the rolls. This is covered with a mixture of grease and emery or alundum. The rolls are set about ¾ in. apart and rotated at high speed and the polishing wood is pressed against the rolls and moved sideways back and forth until the rolls attain the desired polish. Aluminium Sheet Production. Part IX. The Hot Breakdown Operation. Part X. Hot Mills. Robert J. Anderson. *Metallurgia,* Vol. 4, Aug. 1931, pages 117-118; Sept. 1931, pages 149-151; Oct. 1931, pages 173-174, 176; Nov. 1931, pages 21-22, 26; Dec. 1931, pages 37-38,40.

Continuations of a series of articles giving a detailed description of aluminum sheet fabrication. JLG (12c)

Investigation of Cold Rolled Steel V2A. G. W. Akimoff. *U. S. S. R.,* No. 404—*Scientific-Research Department Trans Central Aero-Hydrodynamical Inst.* No. 59. Moskow, 1930.

The object of this investigation was to (1) study the possibility of improvement of the mechanical properties of V2A steel by means of cold working alone; (2) study the influence of the cold work on the chemical stability of steel in the sea water and in the acids; (3) study the structural changes resulting from the cold rolling of steel. Hot rolled Krupp's sheet steel, grade V2A, was investigated. The thickness of the sheets was 1mm. and 2mm. Chemical composition of the steels used in this investigation was as follows:

Type	C	Cr	Ni	Si	Mn
No. 13 (2 mm.)	0.11	18.35	8.96	0.66	0.35
No. 10 (1 mm.)	0.13	18.20	10.06	0.55	0.40

The sheets were cold rolled and the following 2 series were obtained:

SERIES 1

	Original material	Cold rolled material		
	13	13/1	13/2	13/3
Thickness of sheet in mm.	2.2	1.55	1.0	0.52
Reduction in %	0	30	55	76

SERIES 2

	Original material	Cold rolled material			
	10	10/1	10/2	10/3	10/4
Thickness of sheet in mm.	1	0.84	0.62	0.42	0.37
Reduction in %	0	16	38	58	63

The investigation showed that the cold rolled sheet steel of V2A type is possessing both high mechanical properties and high chemical stability and is of great value for various structural purposes. These cold rolled steels may be classified as follows:

1. *Steel reduced by cold deformation from 25% to 40%.*

The mechanical properties are: ultimate strength = 100 to 120 kg./mm.^{2}, the proportional limit = 75 to 90 kg./mm.^{2}, elongation 18 to 12%.

2. *Steel reduced by cold deformation from 60% to 75%.*

The mechanical properties are: ultimate strength = 140 to 150 kg./mm.^{2}, the proportional limit = 110 to 130 kg./mm.^{2}, elongation = 3% to 5%. The steel can be bent, and bends of small radii can be obtained. Elimination of the heat treatment makes it possible to obtain smooth unbuckled sheets. Seamless tubing can be made by cold rolling to the dimensions required, after the first passes were made in hot condition. Metallographic examination showed that the highly deformed metal possessed a normal structure. No transformation of the solid solution and no precipitation of carbides during the cold deformation were observed. All the steels, hot rolled as well as cold rolled, were perfectly stable in sea water and in 20% HNO_3 solution, both at 70°-80° C and at lower temperatures. The steels of type No. 13 are subject to corrosion in cold hydrochloric acid; the corrosion increases uniformly with the degree of cold deformation. In case of steels of type No. 10 treated with hot hydrochloric acid there is no pronounced difference in the rate of corrosion; no definite relation is established between the rate of corrosion and the degree of deformation. In the case of steels of both types in hot sulphuric acid it was found that: (1) the original hot rolled metal is subject to intense corrosion; (2) the cold rolled metal is perfectly stable when reduction is 16% (type No. 10) and 30% (type No. 13); (3) when the amount of reduction is over 30% there was a severe corrosion; the loss in weight being about twice as large as that of the original material. In a 3% NaCl, 3% H_2O solution there was a slight corrosion; the intensity was reduced by nearly half for the cold rolled material with a 30% reduction (class $\frac{13}{1}$ steel) as compared with the hot rolled metal. A greater corrosion was obtained when reduction was above 30%, so that for 76% reduction the rate of corrosion was about equal to that of the original hot rolled metal. AIK (12c)

The Process of Wear of Turning Tools Made of High Speed Steel and Straight Carbon Steel (Ueber den Abnutzungsvorgang von Drehmessern aus Schnelldrehstahl und Kohlenstoffstahl. F. Rapatz & H. Pollack. *Stahl und Eisen,* Vol. 51, Dec. 10, 1931, pages 1538-1539.

In rough turning with high speed steel tools, the wear does not take place at the edge of the tool but somewhat behind it. It is generally assumed that tools of carbon steel do not show such type of wear; wear starts at the edge of the tool. Comparative tests with carbon and high speed steel tools indicate that the above assumption does not hold true. In rough turning, grooves are gradually formed behind the edge on both carbon steel and high speed steel tools. The appearance of the grooves depends upon the speed of cutting. In smoothing, the wear starts on the edge for both the carbon steel and high speed steel tool. GN (12g)

Judging the Surface Condition in Machining Tests. (Die Bewertung der Oberflächengüte bei Zerspanungsversuchen.) K. Schmiz. *Stahl und Eisen,* Vol. 51, Nov. 12, 1931, pages 1402-1403.

In tests to compare the smoothness of machined surfaces of steels, the author used an instrument described by G. Schmalz, *Zeitschrift Verein deutscher Ingenieure,* Vol. 73, 1929, pages 1461-1467, and developed by the Institute für Messtechnik und Austauschbau of the Technische Hochschule Dresden. Shafts of 8 different steels having diameters of about 38 mm. were used in turning with depths of cut of 1 mm. and feeds of 1.15 mm. Every steel was tested with cutting speeds of 12, 24, 48, 70 and 96 m./min. The surfaces appearing at the various speeds are shown and in a diagram the uneveness of the surface was plotted against the speed of cutting. The results are as follows: The tile-shaped chips disappear with the steels containing a higher content of carbon, or better, having a higher tensile strength at lower cutting speeds than with the steels of a lower tensile strength. Former investigations revealing that the smoothness of the machined surface improves with increasing cutting speed are confirmed. GN (12g)

Economical Boring and Milling. (Wirtschaftliches Bohren und Fräsen.) H. J. Stoewer. *Maschinenbau,* Vol. 10, Feb. 19, 1931, pages 117-119.

Economical boring and milling operations may be obtained in practice by using hard metal tools, correctly shaped tools and machines, and carefully installed machines and tools, by standardization and by use of knowledge based on scientific tests. MAB (12g)

New Tests on Cutting of Tools. (Nouveaux essais sur la coupe des outils et sur l'usinage.) L. Persoz. *Aciers Speciaux Métaux et Alliages,* Vol. 6, July 1931, pages 333-346.

Translation of article by F. Schwerd, *Stahl und Eisen,* Vol. 51, Apr. 16, 1931, pages 481-491. It is not possible to follow with the eye exactly how the high speed machine tool cutting operation proceeds. By means of a cinematographic camera, which was developed by C. Cranz in Berlin, the author was able to get a clear picture at a speed of 10 exposures per 1/1000 sec., with illumination of 1/1,000,000 sec. A great number of photographs are reproduced showing cutting tools in operation on steel and cast iron, working at different speeds, different cutting angles, and varying depths of cut. See also *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 19. GTM (12g)

Machinability Properties of Some Cold Drawn Steels. (Bearbeitbarkeitseigenschaften einiger Kalt gezogener Stähle.) F. Rapatz. *Stahl und Eisen,* Vol. 52, Jan. 21, 1932, pages 71-72.

The writer summarizes the results of others, making graphs for all properties of machinability by the various methods. Brinell hardness, moment of rotation, feed pressures, and depth of penetration in drilling, cutting pressures in planing, etc. for 13 steels. Compositions of an ordinary and easily machinable steel are:

	C	Si	Mn	P	S	Cr	Mo
(1) Ordinary	0.06	0.18	0.31	0.012	0.022	13.35	....
(2) Easy to machine	0.09	0.14	0.30	0.016	0.46	15.15	0.25

Cause for this property is explained by sulphide lines in crystal structure, produced by molybdenum sulphide. However, data is not presented regarding rates of cutting and standards. DTR (12g)

Drawing & Stamping (12h)

The Bessemer Process and its Product. R. S. McCaffery. *Rolling Mill Journal,* Vol. 5, Oct. 1931, pages 675-676.

A brief discussion of recent developments: Bessemer steel wires, for instance, can be reduced from No. 5 gage to No. 19 or 20 gage without annealing, whereas open-hearth steel would require two or three anneals for the same reduction. The precautions to observe in order to turn out a flawless material are discussed. Ha (12h)

Thin Strip Steel for Deep Drawing. H. T. Morton & I. A. Rummler. *Metal Stampings,* Vol. 4, Oct. 1931, pages 819-820, 840.

The test methods for judging thin sheets for deep-drawing are discussed. Hardness (Brinell) test, cup-forming tests and bending tests, in their relative appropriateness, are treated. A small percentage of strips from each shipment should, also, be examined for surface conditions, size tolerances and internal defects. The analyses of 2 steels, S.A.E. 1010 cold rolled and S.A.E. 1010 hot rolled, both suitable for the process, are given. Ha (12h)

Deep Drawing of Sheet Metal on Wooden Molds. A New Shaping Method for the Manufacture of Coach Parts. (Blechziehen über holzerne Formen. Ein neues Streckverfahren zur Herstellung von Karosserieteilen.) O. Kühner. *Maschinenbau,* Vol. 10, Jan. 1, 1931, pages 7-8.

The manufacture of relatively small sheet-metal parts under conditions where a draw bench would be uneconomical is discussed. The sheet, held at each end is forced into a mold at the center by means of a wooden plunger. MAB (12h)

DEFECTS (13)

The Nature of Defective Laminations in Wrought-Iron Bars and Chain Links. H. J. Gough & A. J. Murphy. *Engineering*, Vol. 131, May 15, 1931, pages 653-655; discussion, May 22, 1931, page 680.

Condensed from Communication from the National Physical Laboratory, read before the Iron and Steel Institute, London, May 8, 1931. See *Metals & Alloys*, Vol. 2, Nov., 1931, page 273. LFM (13)

On the Cause of Inverse Segregation. Kei Iokibe. *Science Reports of the Tohoku Imperial University*, Sendai, Japan, Vol. 20, Oct. 1931, pages 608-648.

After an exhaustive review on previous work on inverse segregation the author describes his experiments with electrolytic Cu, electrolytic Zn, and of 99.9% pure Sn. From the results of the detailed examination of contraction at various points of the chill cast ingots the mechanism of inverse segregation has been explained as follows: The solidification shrinkage of primary crystals at the outer portion of the ingot causes the outward movement of the mother liquid from the inner portion. The liquids thus flowing toward the outer surface become impoverished with respect to the component of higher melting point, i.e., relatively pure, primary constituents are left in the center causing the enrichment of the secondary component at the outside. 37 references. Non-metallic Inclusions in Steel. Charles H. Herty, Jr. (Pittsburgh Station, U. S. Bureau of Mines). *Transactions American Society for Steel Treating*, Vol. 19, Nov. 1931, pages 1-40; *Metal Progress*, Vol. 20, Oct. 1931, pages 37-42.

Sixth Campbell Memorial Lecture delivered before the Boston Convention of the Society, Sept. 1931. 22 references are cited. Non-metallic inclusions in steel have been a direct cause of great expense to steel makers in inspection and rejection. The sources of inclusions and methods of manufacture suited to their elimination are pointed out. A study of S and O free alloys must be made to form a base line for comparison of commercial steels and steel-making methods. Available data point to large inclusions as most harmful to the physical properties. The importance of oxides and sulphides where certain metallographic structures are to be obtained or avoided is discussed. The fact is emphasized that the steel consumer often imposes an impossible burden in specifications on the maker. Coöperation between consumer and maker is urged as a solution of this situation to the end that the steel maker may use the methods and materials best suited to the production of the quality of steel required by the consumer. WLC (13)

A New Type of Inclusion in Cast Iron and its Relation to Silicon and Manganese Content. F. J. Cook. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Oct. 1931, pages 423-439.

Failure of Steel in Machine Parts. L. T. Holt. *Steel*, Vol. 89, Aug. 20, 1931, pages 31-33.

Some of the principal causes of failures are caused by notch fatigue, insufficient heat treatment, tool marks, and the presence of inclusions. Means of detecting them by macrographic and micrographic testing are discussed. Ha (13)

Formation and Elimination of Non-Metallic Inclusions in the Acid Open-Hearth Process. C. H. Herty, Jr. & J. E. Jacobs. *Transactions American Society for Steel Treating*, Vol. 19, Jan. 1932, pages 271-288; *Blast Furnace & Steel Plant*, Vol. 19, Apr. 1931, pages 553-556; May 1931, pages 683-686.

Five references are cited. The paper gives a brief summary of acid open-hearth furnace practice. A study of the elimination of the non-metallic matter derived from the charge shows it to be partially effected by the oring but that the addition of spiegel in the ore facilitates their elimination. Use of a Mn-Si alloy followed by small additions of Mn effectively eliminates SiO_2 inclusions coming from the bottom due to the boiling action. At the ending of the working period the oxide content of the bath can be controlled by changes in the slag composition, viscosity and temperature. Mn-Si alloy gives a much cleaner steel in the furnace than Mn and Si alloys separately. Holding the ladle and pouring on the cold rather than the hot side is beneficial in the elimination of non-metallic matter. Ha + WLC (13)

Loose Wheel Tires of Locomotives. (Ueber lose Radreifen an Lokomotiven.) Ludwig Koch. *Organ Fortschritte des Eisenbahnwesens*, Vol. 86, Feb. 15, 1931, pages 118-122.

Observations of the German State Railroads are communicated according to which it is not a rare occurrence that the tires on the wheels of locomotives become loose. The reasons for this rather costly occurrence can not be cleared up at present. Faulty treatment in the shop in pressing the tire on, and the greater effect of modern brakes can be considered as reasons. It is recommended to specify exact dimensions for wheel and tire for shrinkage the latter on the wheel and to see that they are observed in the shop. Ha (13)

Notch Load (Die Entlastungskerbe). A. Thum & S. Berg. *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 2, Oct. 1931, pages 345-351.

The detrimental effect of notches which are unavoidable and always present in structures and which, due to vibrating loads, produce a reduction in the endurance strength, may be modified by the use of supplementary notches adjacent to the notches occasioned by the construction. By long-time notch tests it is shown how this is carried out. Model tests show further evidence of the satisfactory effect of additional notches and bores by alleviation of the thickness of the lines of stress. MAB (13)

Effect of Inclusions on Impact Strength of Steel. A. B. Kinzel & Walter Crafts. *Rolling Mill Journal*, Vol. 5, Feb. 1931, page 90.

Abstract of a paper presented at a meeting of the American Institute of Mining & Metallurgical Engineers, held in New York, week of Feb. 16, 1931. See *Metals & Alloys*, Vol. 2, July 1931, page 136. JN (13)

CHEMICAL ANALYSIS (14)

The Volumetric Determination of Tin in White Antifriction Metals. (Sulla determinazione volumetrica dello stagno nei metalli bianchi antifrizione.) D. Lombardo. *La Metallurgia Italiana*, Vol. 24, Jan. 1932, pages 10-20; *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 13, 1931, page 883.

Study of reduction to stannous Sn, in a CO_2 atmosphere, by Pb (containing 3% Sb) and by Armco iron, prior to titration by iodine. Fair results are obtained with reduction by Pb if the empirical factor 0.00599 g. Sn per cc. of n/10 iodine is used. With Fe as reducing agent the theoretical factor gives satisfactory results in alloys of less than 38% Pb. In higher Pb alloys results may be 0.20-0.35% low. The Sb content of the solution should be, or brought to, at least 12 parts Sb to 100 Sn. Copper up to 23% does not interfere, nor does As in amounts normally present. The determinations on which these conclusions are based are tabulated in detail. Ha + HWG (14)

On the Position of Uranium-Z in the Order of the Uranium Decomposition Succession (Ueber die Stellung des Uran-Z in der Uranzerfallsreihe). E. Walling (Kaiser Wilhelm Institut für Chemie, Berlin-Dahlem). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 14, Oct. 1931, pages 290-296.

A quantitative Uranium-Z determination showed that UX_1 represents the parent substance of U-Z. EF (14)

The Practice of Spectrum Analysis with Hilger Instruments. Compiled by F. Twyman. Adam Hilger, Ltd., London, 1931. Cloth, 6 x 9¾ inches, 53 pages. Price 3s. 6d.

This paper is an attempt to sell spectrographic analysis and incidentally the publisher's equipment to all interested in chemical analysis. Very little direct advertising is used, however, only occasional reference to the model of instrument best suited for a particular type of work. Many references to the literature are given in the text, followed by a bibliography of 78 publications. The booklet is composed of 6 chapters which include considerable pertinent and condensed information on all branches of spectroscopy and is well worth its low cost. C. P. Larrabee. (14)-B-

The Determination of Silver in Gold Bars. (Silberbestimmung in Goldbarren.) F. Michel. *Chemiker Zeitung*, Vol. 55, Sept. 23, 1931, pages 731-732.

Usually Ag is determined by the difference between the Au + Ag and the Au determinations. This causes errors up to 0.01. A number of ¼ g. samples of synthetic alloys of pure Au, Ag and Cu were analyzed. In alloys low in Au, the Ag result was low and in alloys high in Au, the Ag result was high. This was at least partly due to the quantity of Pb used in the cupel. For accurate results, analysis by the usual method is recommended; then make up a synthetic alloy of the same composition and check it by the same method using the same quantity of Pb. If the Ag result in the sample was lower than in the check, subtract the difference from it and vice versa. CEM (14)

A New Method of Checking the Catalytic Effect of the System Pd-H by Means of Resistance Measurements (Ueber eine neue Methode zur Verfolgung der katalytischen wirkungen des Systems Palladium-Wasserstoff mit Hilfe von Widerstandsmessungen). C. A. Knorr (Technische Hochschule München). *Zeitschrift für physikalische Chemie*, Abt. 2, Vol. 157, Nov. 1931, pages 143-163.

A modified method of electric resistance measurement was employed and the factors governing the hydrogen liberation from Pd were studied. EF (14)

The Chemistry of Rhenium, II. The Determination of Rhenium as Thallium Perrhenate. (Beiträge zur Chemie des Rhenium, II. Die Bestimmung des Rheniums als Thallium—Perrhenate.) F. Krauss & H. Steinfeld. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 197, Mar. 24, 1931, pages 52-56.

The production of thallium perrhenate is described and its properties are discussed. Instructions for the determination of rhenium as thallium perrhenate are given. Ha (14)

The Cathode Ray Tube in X-Ray Spectroscopy and Quantitative Analysis. Gorton R. Fonda & George B. Collins. *Journal American Chemical Society*, Vol. 53, Jan. 1931, pages 113-125.

The Conditions for Precipitation of Polonium and Some of Its Complex Dérivatives. I. Centrifugal Study of the Reactions of Precipitation of Various Compositions of Polonium without Adding a Precipitator. (Sur les conditions de précipitation du polonium et sur quelques-uns de ses derives complexes. I. Etude, par centrifugation, des reactions de precipitation de divers composes du polonium sans addition d'entraineur.) M. Guillot. *Journal de chimie physique*, Vol. 28, Jan. 1931, pages 14-41.

Every time the precipitation of polonium with a very small quantity of a derived foreign metal is practically completed, an insoluble derivative of polonium is formed, precipitated under the same experimental conditions. These conditions are: (1) When polonium is soluble, but the precipitator is sufficiently crystallized to see evidence of solid solution; (2) When polonium is insoluble and the total precipitation is composed of a metal insoluble in water but soluble under any other chemical reaction in another neutral solvent in which it can crystallize easily. Hence a composition of trivalent polonium in insoluble, can be totally precipitated by a composition of a bivalent metal, with the condition that both be extremely insoluble. MAB (14)

Separation of Nickel from Cobalt Metal or Ferro-Cobalt. H. A. Kar. *Chemist-Analyst*, Vol. 20, Mar. 1931, page 15.

Dissolve 1 g. sample in 50 cc. HNO_3, Sp. Gr. 1.2, neutralize with NH_4OH and add 50 cc. excess. Add 10-15 g. NH_4SO_4 and boil 10 minutes. Filter off $Fe(OH)_3$ and MnO_2 and wash. Cool, add 200 g. NH_4Cl and dilute to 400 cc. Add 1% dimethyl glyoxime solution in alcohol and allow precipitate to settle one hour. Filter and redissolve in HNO_3. Repeat the precipitation as before. Filter on paper and ignite in a weighed Pt crucible, slowly at first, finally at red heat, and weigh NiO. NH_4SO_4 oxidizes $Co(OH)_2$ to $Co(OH)_3$ which does not precipitate. CEM (14)

ECONOMIC (16)

Efficiency in Steel Plants (Betriebswirtschaft in Energiebetrieben.) G. Veit. *Stahl und Eisen*, Vol. 51, Oct. 29, 1931, page 1344; Nov. 5, 1931, pages 1379-1380; Nov. 12, 1931, page 1407.
It is shown how a careful investigation of the conditions of operation of a large German steel plant revealed an excessive consumption of water, steam and electric current. After improving the conditions, the costs could be essentially decreased; the water cost was reduced by about 60%, the cost of steam, by 26% and the cost of electric current by 14%. GN (16)

Influence of the Construction of Castings on the Cost of Manufacture. (Einfluss der Konstruktion von Gussstücken auf den Herstellungenspreis.) Heinrich Tillmann. *Maschinenbau*, Vol. 10, Aug. 20, 1931, pages 525-529.
The "right and wrong" ways of constructing castings are given, and the differences are clearly emphasized to show how the models or the castings can be manufactured cheaper. The individual things which go to make the castings cheaper and the value of standardized operating of the units in the construction of models and in foundry practice are brought out. Suggestions for further combined operations are given. MAB (16)

"Dull" Year's Iron Ore Train Reaches Twice Across Continent. A. J. Hain. *Steel*, Vol. 88, Jan. 29, 1931, pages 35-37, 53.
The Lake Superior district shipped 47,187,661 gross tons of iron ore in 1930. This is 28% less than in 1929 but only 9% less than the annual average for the previous 10 yrs. The author gives a set of tables and charts showing the amounts of ore shipped from the individual mines in each range of the Lake Superior district in 1929 and 1930. JN (16)

Mineral Resources of the United States, 1930, Summary. O. E. Kiessling, *et al.* *Mineral Resources of the United States*, 1930, *United States Bureau of Mines*, Part 1, Nov. 9, 1931, pages A1-A120.
The value of all mineral products in the U. S. in 1930 was \$4,810,400,000, a decline of 18% from 1929 and the lowest figure since 1922. Mineral fuels declined 14%, metals 33% and non-metals 12%. Cu, Fe, Pb, Ag and Zn declined 30-49%. Au alone among the metals gained. Natural gas production increased. Quantity and value gains were registered by As, borates, Br, Ca-Mg chloride, fuller's earth and phosphate rock. Output alone gained for pyrite, asbestos and mica. Detailed figures of quantity and value for 1929 and 1930 are given tabularly for each product. AHE (16)

Soviet Copper Development. Correspondence from M. Karashov, Moscow, U. S. S. R. *Metal Progress*, Vol. 21, Jan. 1932, pages 69-70.
Describes Kounrad copper deposits comparable to Utah deposits in the United States. Estimated production of these deposits by 1933 is 1,000,000 lbs. of copper daily. WLC (16)

Arsenic, Bismuth, Selenium and Tellurium in 1930. V. C. Heikes. *Mineral Resources of the United States*, 1930, *United States Bureau of Mines*, Part 1, Nov. 4, 1931, pages 25-30.
Production of As as As_2O_3 in the United States in 1930 was 17,057 short tons. Al was a by-product from smelting Cu and Pb ores. Bi was reported recovered at but 1 refinery in 1930. 3 companies reported a 1930 output of 454,769 lbs. of Se. Te production was 14,095 lbs. AHE (16)

Determination of Pipe Diameters for Maximum Economy. C. W. Harris. *Engineering News Record*, Vol. 106, Jan. 15, 1931, page 101.
Determination of the economic size of pipe for long lines has generally been treated as a problem depending on specific conditions of the individual case. The author shows that the principal factors involved in economic studies are independent of local conditions. From the theoretical investigation, it can be concluded that, for minimum weight and constant factor of safety, the size of any high pressure steel pipe should vary throughout the profile so that the diameters at all successive points will be inversely proportional to the seventh root of their respective pressure heads. Ha (16)

Iron Mine Operators Prepare for More Active Season. A. J. Hain. *Steel*, Vol. 88, Jan. 8, 1931, pages 46-48.
A discussion of the changes in leases, ownership and control of mines in the Lake Superior region during 1930 with notes on drilling operations, construction of new shafts and opening of new mines. JN (16)

Progress in Copper Production. *Metallurgist*, Mar. 1931, pages 43-44.
An extended abstract of Dr. Ernst Hentze's review of the developments in copper production from 1920 to 1930 appearing in the first issue of *Metall und Erz* for 1931. VVK (16)

The British Steel Foundry Industry in 1931. J. Deschamps. *Foundry Trade Journal*, Vol. 46, Jan. 14, 1932, page 20.
A brief summary, with tables, covering British production, imports and exports of steel castings during the year 1931.

Platinum and Allied Metals in 1930. Hubert W. Davis. *Mineral Resources of the United States*, 1930, *United States Bureau of Mines*, Part 1, Nov. 16, 1931, pages 99-112.
In 1930, 385 troy oz. of crude Pt was produced in Alaska, 129 oz. in California, and 13 oz. in Oregon, a total of 527 oz. for the U. S. Domestic refiners recovered 37,780 oz. Pt, 3801 oz. Pd, 1468 oz. Ir, 334 oz. osmiridium and 119 oz. of other Pt metals, a total of 43,502 oz. Recovery from secondary sources was Pt 33,787 oz., Pd 7426 oz., Ir 4,354 oz., and others 1,749 oz., a total of 47,316 oz. AHE (16)

Iron Ore, Pig Iron and Steel in 1930. Hubert W. Davis. *Mineral Resources of the United States*, 1930, *United States Bureau of Mines*, Part 1, Nov. 19, 1931, pages 57-98.
In 1930, production of Fe ore decreased 20% and shipments 27% from 1929. The output of pig Fe (including ferrous alloys) decreased 25%. For the first time since 1927, building and construction was the leading consumer, using 19% of the output (16.5% in 1929). The automobile industry used 15.5% (18% in 1929) and railroads 15% (17% in 1929). Domestic output of pig Fe required about 60% of the capacity. Production of steel ingots was about 59% of the rated capacity. AHE (16)

Gold, Silver, Copper, Lead and Zinc in the Eastern States in 1930. J. P. Dunlop. *Mineral Resources of the United States*, 1930, *United States Bureau of Mines*, Part. 1, Oct. 7, 1931, pages 17-23.
The production of Au, Ag, Cu, Pb and Zn in the Eastern States in 1930 increased over 1929 but owing to the lower prices of Ag, Cu and Zn, the value of the production of each and of the total for all 5 metals declined. Production was Au \$46,637; Ag 123,590 oz., \$47,582; Cu 38,232,031 lb., \$4,970,-164; Pb 16,734,000 lb., \$836,700; Zn 336,488,000 lb., \$18,126,878; and total \$24,027,961. AHE (16)

The Pig Iron Situation. E. J. Fox. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 75-76.
An urge for tariff protection for British pig iron. CHL (16)

Iron Mining in Spain (La Mineria De Hierra En Espana). Luis Barreiro. *Revista Minera*, No. 3289, Nov. 1931, pages 530-531.
An economic discussion of iron mining in Spain. Production of iron in thousands of tons from 1913 to 1930 inclusive; maximum, 1913, 9,861; minimum, 1921, 2,602; 1930, 5,408. This decrease is due to the number of miners employed: 1913—33,678; 1929—16,358. DTR (16)

Does the United States Need a Tariff on Copper? Percy E. Barbour. *Mining and Metallurgical Society of America, Bulletin* No. 222, Vol. 24, Dec. 1931, pages 94-102.
Discussing this question from the angle that the United States is the greatest Cu producer in the world and has invested very largely in the Cu industries in other countries, especially South America, the need for a tariff is denied.

Tin—Its Past, Present Plight, and Future. H. E. Ellefsen (Bolivia). *Mining Journal*, London, Vol. 176, Jan. 2, 1932, pages 5-6; Jan. 9, pages 21-22.
A general economic discussion. AHE (16)

The World's Silver Situation. W. Mont Ferry (Silver Producers Association). *Mining Congress Journal*, Vol. 17, Dec. 1931, pages 660-661, 669.
Presented at meeting of Western Division, American Mining Congress, September 1931. The buying power of half of the people of the world can not be destroyed without profoundly and adversely affecting world industry; the world's gold is inadequate to support the world's credit structure. Silver should be restored to its historic place as a basic money. Our so-called over-production is a myth; lack of distribution and destruction of buying power among people who are potential purchasers are the cause of all stagnation of international commerce. The use of silver as a recognized money is the only remedy in sight. DTR (16)

The Malleable Castings Industry in 1931. A. W. G. Bagshawe. *Foundry Trade Journal*, Vol. 46, Jan. 14, 1932, pages 37, 39.
A brief article dealing with the malleable castings industry in Great Britain during 1931. Particular attention is given to the use of rotary and semi-rotary furnaces for the melting of malleable iron, and the fact is noted that five or six of these furnaces, in which pulverized fuel will be employed, are being built in Great Britain and Europe at the present time. OWE (16)

The Automatic Increase of Price of the Liquid Iron at Insufficient Yield (Die automatische Verteuerung des flüssigen Eisens bei nicht genügenden Ausbringen). W. Bremer. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, pages 857-858.
By "yield" is meant the ratio of the weight of good castings to the weight of the charge. Tables and curves demonstrate that too small a yield increases the cost of the cold charge and the melting costs. It is emphasized that this reason for losses should be eliminated as far as possible.

Copper Consumption In The United States. *American Metal Market*, Vol. 38, Apr. 25, 1931, pages 2-3.
Reported by American Bureau of Metal Statistics. Use of Cu, industrially classified, in the U. S. in 1930. Also comparative diagram of consumption and domestic deliveries of refined Cu from 1920 to 1930. DTR (16)

The Group Bonus System. A. L. Ainsworth. *Canadian Foundryman*, Vol. 22, Oct. 1931, pages 15-16.
An article dealing with the application of the group bonus system in the De Forest Crossley plant at Toronto. OWE (16)

The Importance of Heat Balances and Heat Statistics in an Iron Works (Värmebalansers och värmestatistiks betydelse vid järnverk). Ake Anjou. *Jernkontorets Annaler*, Proceedings of the Annual Meeting, May 30, 1931, Vol. 114, 1931, pages 86-132.
An analysis is made of the heat losses in Swedish iron works and a plea is made for employment of a greater number of heat engineers as in German practice. In the discussion following the paper, it is pointed out that quality is so important a factor in Swedish steel products that too much emphasis can not be placed on heat economy. A very good discussion of German practice in heat control is given. HCD (16)

MISCELLANEOUS (20)

Coke Oven Design. G. W. J. Bradley. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 87-94, 102.

A discussion of the coking process dwelling on the essential conditions for the production of good coke, i. e. uniform heating of the oven together with a correct width of oven. The means of securing an even distribution of gas and air throughout the length of the oven are treated. 11 types of oven are dealt with as regards their differences in construction, while setting forth their claims for superiority. They are the Becker oven, the Collin oven, the Coppée Isothermal oven, the Gibbons Kogag oven, the Koppers oven, the Otto oven, the Piette oven, the Semet Solvay oven, the Carl Still oven, the Simon Carves oven, and the Wilputte oven. CHL (20)

Standardization—Transportation, Ferrous Metallurgy and Non-Ferrous Metallurgy Projects. American Standards Association. *American Standards Association Bulletin,* No. 60, Apr. 1931, pages 25-29.

List of specifications developed or being developed under A.S.A. procedure in these fields. 10 refer to electric railway rails and track materials. 18 refer to steel, wrought iron, Zn, zinc coatings, Cu, brass, bronze, solder and plumbago crucibles. HWG (20)

Patent Rights for Scientific Discoveries. C. J. Hamson. Bobbs-Merrill Co., Indianapolis, 1930. Cloth, 6 x 9¼ inches, 286 pages. Price $4.50.

This monograph won the prize for 1929 of the Linthicum Foundation. Linthicum was patent counsel for the U. S. Steel Corporation and lecturer on patent law at Northwestern University. As a memorial, friends established the prize fund for research in patent law. The 1929 topic was "Scientific Property." Hamson is an English lawyer.

Some French savants advanced the idea that scientists discovering scientific principles of the type not now patentable should be rewarded by industrial firms that, in the course of time, manufacture anything that is an outgrowth of the discoveries. Radio, had such a scheme been in vogue, would now pay tribute to all the many scientists whose work underlies the industry. It is claimed that in France a bill securing rights of scientists to such tribute is "very likely to be passed in the near future." Since science is international, the matter has been put up to the League of Nations, which has been studying it for 7 years, its experts invariably approving the fundamental proposition. The International Union of Pure and Applied Chemistry actively advocates the scheme. Partial governmental approval of the proposal forwarded by the League of Nations was indicated by the replies of Belgium and Brazil only. The National Research Council of the United States considers that proprietary right over discoveries is not realizable and doubts that it is desirable.

Hamson discusses the history of the project, recognizes that so many discoveries are utilized in the manufacture of any modern product, and the time (50 years) suggested for the period in which tribute is to be paid, so long, that the only way a firm could do business under such a scheme would be to insure itself against litigation and exactions by buying a blanket right to utilize all discoveries.

Hence, he proposes an international corporation to administer the scheme. All suggestions are complicated and hazy and though Hamson argues that a workable scheme could be evolved, very few of the opinions he cites agree with him.

The scheme seems aimed to involve compulsory tribute designed to be used to encourage research. It appears entirely calculated to be an unmitigated nuisance to industry and quite opposed to the American way of doing things. There does not seem any immediate danger of international action and the fact that it is to some degree sponsored by the League of Nations would surely subject the scheme to careful study before even the most radical U. S. Congress would adopt it.

The preface says, "The unorganized army of men of science everywhere find here opened before them a prospect of just and material reward. The cohorts of the Patent Bar are those who can formulate and administer the measure when it becomes accepted. To these 2 classes in the community a vast field of possibilities is opened. It is time that the professional men of America awaken and take a hand in the debate."

It would appear that any such attempt on the part of patent lawyers to saddle industry with more difficulties and litigation analogous to those already imposed by our faulty patent system should be resented and opposed alike by industry and science. Voluntary coalition for support of pure research is one thing. Exaction of involuntary tribute is quite another. The scheme is unwieldy and unworkable without huge costs for bureaucratic administration and for litigation. It would surely delight the average patent lawyer to have a whole new field of opportunities for litigation. The book might well be read by scientists so they may be ready to combat the impractical visionaries and the "cohorts of the Patent Bar" who may seek to foist such schemes upon industry. H. W. Gillett (20)-B-

The Electric Precipitation of Dust and the Electric Cleaning of Blast-Furnace Gases (La précipitation electrique des poussieres et l'épuration électrique des gas de hauts fourneux). Keraly. *L'Industrie Electrique,* Vol. 40, Apr. 25, 1931, pages 173-180.

The principle of electric precipitation is explained and the history of its development is briefly described. A modern installation of 240,000 in.^{3}/hr. is described in detail; the best arrangement of such a plant and the electric equipment is discussed. Ha (20)

Investigation of Different Methods to Determine the Roughness of Metallic Surfaces (Untersuchung verschiedener Methoden zur Bestimmung der Unebenheiten (Rauhigkeiten) von Metallflächen). W. Kiesewetter. *Feinmechanik und Präzision,* Vol. 39, Dec. 1, 1931, pages 211-215.

A method of making a perfect cast of a surface and an optical method to make visible and record the unevenness on it is described and illustrated by many examples. Ha (20)

Patent Law for Chemical and Metallurgical Industries. A. W. Deller. Chemical Catalog Co., Inc., New York, 1931. Cloth, 6 x 9 inches, 483 pages. Price $6.00.

Most books on patent law and procedure are pretty hard reading for the metallurgist. This one, however, draws so many of its examples from the metallurgical field that it can be readily followed.

The reviewer does not agree with the opinion quoted in the book, of a Japanese investigator sent over to look into the U. S. Patent System who ascribed the greatness of the U. S. to that system. But since we are saddled with the system and must play the game according to the rules, it is necessary to know what the rules are. This book is, to the metallurgist, at least, the most useful one of its type we have yet seen, for it explains the rules from the metallurgist's point of view and not exclusively from a lawyer's point of view.

It covers the history, theory and nature of patents, classes of patentable inventions, persons entitled to patents, principles of patentability, acquisition and termination of patents, remedy of defective patents, form and construction, infringement and infringement suits, ownership of patents, commercial phases and foreign patents.

An appendix of miscellaneous statistics covering such things as production of metals and minerals and a tabulation of the developed and potential interpower of the world does not seem very germaine to the subject of the book, but at least does no harm. H. W. Gillett (20)-B-

The Catalytic Reduction of Carbon Monoxide under Ordinary Pressure. IX. Tests with the Co-Cu-MgO-Catalyzer. X. Tests on the Influences of Some Materials on the Catalytic Action of the Co-Cu-MgO-Catalyzer. (Ueber die katalytische Reduktion des Kohlenoxyds unter gewöhnlichem Druck. IX. Versuche mit dem Co-Cu-MgO-Katalysator. X. Versuche über die Einflüsse einiger Stoffe auf die katalytische Wirkung des Co-Cu-MgO-Katalysators.) K. Fujimura. *Scientific Papers of the Institute of Physical & Chemical Research,* Vol. 17, Nov. 1931, page 11-21.

The most suitable catalyzer for the synthesis of petroleum has been found to be the Co-Cu-Mn catalyzer where the constituents are present in the ratio 3:1: (15% of Co); the activity of this catalyzer was studied with respect to its volume and with additions of other elements. Only thorium or uranium improved its activity, the latter in an amount of 8:1:2:0.4 (in Co-Cu-Mg-U). Ha (20)

Unknown Factors of Safety Present in the Quality and Transformation Processes of Light Metals (Facteurs de sécurité méconnus résidant dans la qualité et les procédés de transformation des métaux légers). R. de Fleury. *Revue de Métallurgie,* Vol. 28, Nov. 1931, pages 610-616.

The final factor of safety of a cast light metal article is an integer of numberless factors both known and unknown entering their manufacturing processes. Some probable causes of defects are mentioned, among them the influence of the remelting of scrap with virgin metal. JDG (20)

Cooling Phenomena in a Steel Block. Tetsu-o Horie. *Tetsu to Hagane,* Vol. 17, Nov. 1931, pages 1104-1125.

A steel containing 0.93% C was finished into a cylindrical block, 416 mm. diameter and 650 mm. long. Thermo-couples were inserted into five holes, 9 mm. diameter, drilled into different depths from the surface to the center of the specimen. At first, the specimen was annealed at 830° C. at which Fe_3C dissolved completely in the austenite, and then 6 cooling curves including that of a point of surface were recorded during cooling of the specimen in the air. From the results thus obtained, it was revealed that the supercooling of Ar_1 transformation was remarkable at the center as well as the surface. This phenomenon is attributed to the fact that the central part is cooled slowly at high temperature by the transformation heat of the outside, but is rapidly cooled through the critical range, because the outside is already cooled to a considerably low temperature at that time. From the cooling curves obtained, cooling rate-temperature curves, cooling rate-time curves, isothermal curves, temperature distribution curves in the steel block, and temperature-cooling rate curves in critical range are drawn. When the specimen was allowed to cool in the air from 690° C., below the A_1 point, the temperature was uniformly lowered from the surface to the center. By cooling it in iron molds, 60 mm. by 30 mm., from 870° C. and 830° C. respectively, it clearly shows that the transformation heat of the outside has almost no effect on the cooling rate of the central part. From these results the author further considered theoretically on steel ingot cooled from the melt and discussed the occurrence of segregation. TS (20)

The Tensions in Undivided Cast-Iron Pulleys in Operation. (Ueber die Betriebsspannungen in ungeteilten gusseisernen Riemenscheiben.) Viktro Heuse. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, Dec. 12, 1931, page 1511-1513.

Based on experiments the tensions occurring in the rim of cast-iron pulleys are analytically treated; it is found that the forces exerted by the pulling agent produce bending stresses in the whole circumference of the pulley rim. The pulley arms are subjected to longitudinal and bending stresses, the arms of the not-loaded part showing in general the same stresses as the arm on the loaded part. It is of greatest importance that the rim is uniformly thick and it is recommended to machine also the inner side of the rim as much as the arms permit. Ha (20)

The Work of the Institute of British Foundrymen in 1931. Andrew Harley. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 38-39, 42.

The author refers to the work of the I.B.F. during 1931, to the fact that three new sections of this organization have been formed during the year and to the importance the Association places upon its educational activities. OWE (20)

Recovery of Metals from Waste Materials. J. W. Hinchley. *Chemical Age,* London, Vol. 23, Dec. 6, 1930, Metallurgical Section, pages 31-32.

A condensation of a paper before the Conference of the Institution of Chemical Engineers on "The Utilization of Trade Wastes." The recovery of iron and steel, copper alloys, bronzes and tin is discussed. See also *Metals & Alloys,* Vol. 3, Feb. 1932, page MA49. VVK (20)

FOUNDRY PRACTICE & APPLIANCES (22)

Loss and Gain in Components when Melting Steel Scrap in the Cupola. E. Piwowarsky, H. Langebeck & H. Nipper. *Canadian Foundryman,* Vol. 22, Sept. 1931, pages 16-17.

Extended abstract of paper which appeared in *Die Giesserei.* See "Conditions of Absorption and Oxidation in Small Cupola Furnaces," *Metals & Alloys,* Vol. 2, Nov. 1931, page 279. OWE (22)

Binding Materials in the Preparation of Core Sands. (Des Agglomérants dans la Préparation des Sables pour Noyaux.) *Revue de Fonderie Moderne,* Vol. 25, Dec. 25, 1931, page 464.

A binding material "colsable" which is supposed to replace others, as linseed oil, molasses, dextrine, etc., is described and ratios of mixture with molding sand given for several purposes. Ha (22)

Testing Electrical Equipment in Foundries. *Foundry Trade Journal,* Vol. 45, Dec. 10, 1931, page 369.

Short article on methods that can be adopted for the testing of electrical equipment in foundries. Special attention is paid to the testing of motors for leakage, and means for making load tests on motors are described. OWE (22)

A Method for Molding a Rope Pulley. Arthur Greenhalgh. *Canadian Foundryman,* Vol. 22, Aug. 1931, pages 17, 22.

Article on the above subject, abstracted elsewhere in this journal. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 319. OWE (22)

Low Carbon Cast Iron from the Cupola (La fonte a basse teneur en carbone au cubilot). M. Kagan. *Revue de Fonderie Moderne,* Vol. 25, Nov. 10, 1931, pages 397-398.

See "Some Remarks on the Foundry Defect Called Dark Spots," *Metals & Alloys,* Vol. 2, Oct. 1931, page 228. Ha (22)

Difficulties in Modern Jobbing Foundry Practice. Kenneth S. Jewson. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, page 35.

The author emphasizes the value of rationalized melting practice and the need for recognition of variables which are likely to arise in jobbing work. Some attention is given to prices and costs. OWE (22)

Progress in Foundry Practice in the Second Half-Year of 1930 (Fortschritte im Giessereiwesen im zweiten Halbjahr 1930). H. Jungbluth & P. A. Heller. *Stahl und Eisen,* Vol. 51, Nov. 5, 1931, pages 1373-1377; Nov. 12, 1931, pages 1404-1407.

The paper reviews 114 articles on foundry practice which have been published all over the world from July to December 1930. The reviewers subdivided the material as follows: (1) structure and properties of cast iron, (2) melting practice, (3) molding and cleaning, (4) general. GN (22)

Tenth Annual Report. *British Cast-Iron Research Association,* Oct. 1931, 16 pages.

The report for the year 1930-1931 contains brief reviews of work carried out in the laboratories of the Association on molding sands and refractories, heat resisting cast-iron, particularly Silal and Nicrosilal, ingot mold iron, cupola melting practice, malleable cast-iron, alloy cast-iron, structure of cast-iron, strength of cast-iron in relation to size and foundry pig iron. Ha (22)

The "Roman Joint" in the Art Foundry. (Le Joint Romain en Fonderie d'Art.) Wisterzee. *Revue de la Fonderie Moderne,* Vol. 25, Dec. 10, 1931, page 452.

A method of joining the parts of large monuments if they can not be cast in one piece is described in order to make the joints invisible. This method was used by the old Romans. Ha (22)

The Effect of Heat on the Permeability of Coal-Dust Facing Sands and Core-Sand Mixtures. Walter M. Saunders & Walter M. Saunders, Jr. *Foundry Trade Journal,* Vol. 45, Nov. 12, 1931, pages 297, 307.

A paper, accompanied by 3 figures and 3 tables, presented and discussed at the 1931 Convention of the American Foundrymen's Association. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. OWE (22)

Meeting the Demand for Aluminum Castings. *Canadian Foundryman,* Vol. 22, Aug. 1931, pages 7-11.

An article, accompanied by 4 photographs and 1 table, in which the characteristics and applications of various sand-cast aluminum alloys are dealt with. Attention is directed to the problems of pattern and core design, of molding sand, and of gating. Melting and the effect of variations in composition resulting from the melting process are discussed, as also are "modification" and heat treatment. The value of inspection and the place which X-ray apparatus finds in aluminum foundry work are also dealt with. OWE (22)

Molds and Cores of Pure Quartz. (Formen und Kerne aus reinem Quarz.) *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 13, 1931, pages 883-884.

Molds made of pure quartz which has been melted in the electric furnace at very high temperatures are of extreme advantage as the quartz is, at all temperatures occurring in the foundry, indestructible and has a practically negligible expansion coefficient. Ha (22)

To Remove Sand from Deep-Cored Pockets. *Canadian Foundryman,* Vol. 22, Oct. 1931, page 19.

A description of the method for removing sand from deep-cored pockets in castings, which has been recommended by the Steel Founders Society of America. OWE (22)

Lead-Base Metal Versus High-Silicon Iron. *Foundry Trade Journal,* Vol. 45, Oct. 8, 1931, page 223.

A description of experience in producing lead-base containers in the iron foundry. Definite information regarding the alloy used is, however, missing from the article. The article is accompanied by one figure. OWE (22)

The Lighting of Foundries. *Foundry Trade Journal,* Vol. 45, Nov. 12, 1931, pages 298, 310.

The article deals with suitable wiring systems for use in foundries. OWE (22)

Synchronous Motor Drives in the Foundry. *Foundry Trade Journal,* Vol. 45, Nov. 26, 1931, page 330.

Advantages of synchronous motors for operating foundry plant are power factor correction, higher efficiencies, and constant speed, irrespective of load conditions. OWE (22)

What Oxidized Scrap can do to Iron. Garnet Phillips. *Foundry,* Vol. 59, Dec. 15, 1931, pages 33-34.

Unusual chilling phenomena were observed by using scrap gray iron that had been oxidized. Data obtained from tests indicate the danger in using large quantities of oxidized scrap in mixtures intended to produce gray iron of any quality. It is suggested that the amount of dissolved iron oxide in the remelted iron is the controlling factor causing the white instead of the gray fracture. VSP (22)

The Testing of Grain Size of Molding Sand. (Die Prüfung der Korngrössen von Formsanden.) G. Suliotti & E. Capello. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 13, 1931, page 883.

The grain size is determined by sieving, floating and washing; from each of these methods, curves are plotted for practical use. Ha (22)

The Standardization of the Foundry Raw Materials. (Die Normung der Giessereirohstoffe.) V. Prever. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Dec. 4, 1931, page 922.

A far-reaching standardization in the following groups is advocated: 1. Raw materials for operation of cupola furnaces. 2. Raw materials for making of cores. 3. Materials for making the mold. Ha (22)

Improvement of Foundry Products and Reduction of their Prices. (Die Verbesserung der Giessereierzeugnisse und die Herabsetzung ihrer Preise.) E. Ronceray. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Dec. 4, 1931, page 922.

Means for improvement of the product and production methods are discussed. Ha (22)

Anomalies in Hardening of Cast Iron (Anomalien beim Härten von Gusseisen). A. Le Thomas. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 6, 1931, page 867.

It has been found that, by adding to the charge a constituent containing about 2-3% Mn, the disagreeable irregularities often occurring in the hardness of castings will be prevented. This method has been found satisfactory in several foundries. Ha (22)

Where are the Young Foundrymen? S. Wells Utley. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 2, Jan. 1931, pages 761-766.

Training is urged which will produce good mechanics, skilled molders, coremakers and furnace operators, as the author believes that there are many boys who will undertake such apprentice courses if they are approached in the proper manner and are shown an opportunity in keeping with modern conditions. CHL (22)

Moulding a Water-Seal Gas-Valve Pan. Robt. Jones. *Foundry Trade Journal,* Vol. 45, Dec. 3, 1931, page 352.

An article accompanied by 9 diagrams showing the method adopted in producing a cast-iron pan with a minimum of pattern making and struck up in the foundry floor. OWE (22)

Some Observations on Synthetic Sand—Its Preparation and Use. L. B. Knight. *Canadian Foundryman,* Vol. 22, Dec. 1931, pages 11-13.

Paper presented before the American Foundrymen's Association. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. OWE (22)

Recent Progress in High Strength Gray Iron (Les fontes a haute résistance, progres récents). R. Lemoine. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 801-809. 5 references.

Very general discussion of pearlitic iron. A resume containing no new data. See also *Metals & Alloys,* Vol. 2, Oct. 1931, page 228. HWG (22)

Operating an Iron Foundry without Pig Iron. Walter Lister. *Foundry Trade Journal,* Vol. 45, Nov. 12, 1931, page 305.

The author describes how, by using an electric furnace and working it on the continuous melting principle, any quantity of iron can be poured at any time during the day and the same floor space and melting equipment used any number of times daily. A description of the best method of working follows and a table quoted gives details of the comparative costs per ton of electrically- and cupola-melted iron. Another table gives details of tests of the two types of iron. A brief editorial criticism refers to the difficulties which are frequently encountered when melting low-carbon cast iron. OWE (22)

Recent Developments in Railway Foundry Practice. T. Henry Turner. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 27-29.

An article, accompanied by 3 photographs, in which a description is given of recent developments in cast steel frames in the United States. Reference is made to the production of the Davis wheel, which has increased somewhat during the year, and to the recent introduction of steel sleepers on the Great Western Railway Company's lines. Special attention is directed to recent developments in the production of locomotive cylinders. A gradual reduction in the number of non-ferrous alloys has been made as a result of the amalgamation of certain railway companies. OWE (22)

Mold-Handling Methods. Wm. L. Hartley. *Iron Age,* Vol. 128, July 16, 1931, pages 172-173, 207-209.

Handling of molds represents between 20 and 40% of all the material handling effort in connection with foundry production. The author discusses and describes methods for the mechanization of this phase of work and layout and arrangement of equipment of the whole plant to achieve a minimum of handling. Ha (22)

Recent Developments in Aluminum Founding. D. Hanson. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 31-32.

The author discusses the troubles which have been found to occur in Al castings due to the formation of pinholes. Experiments have been conducted with a view of showing the effects of hydrogen and water vapour upon the density of virgin Al and various alloys. The desirability of controlling furnace atmospheres is pointed out. Storage conditions may affect the melting characteristics of ingots. Methods which may be adopted to prevent troubles due to pinholes and blowholes and difficulties which arise from the use of gas-free metal are also considered. OWE (22)

The Ellipsoid Furnace. Rotary Oil-Fired Furnace Features Deep Bath. *Foundry Trade Journal,* Vol. 45, Nov. 19, 1931, page 315.

A description, accompanied by 2 photographs, of an oil-fired furnace which has the appearance of a foreshortened furnace of the rotary type, the cylinder being supported circumferentially on two rollers and being permanently tilted so that the metal bath lies in the angle formed by the circumference and the base of the cylinder. The charging door is situated in the top of the cylinder. The furnace is tapped by rotating the cylinder so that the tap hole, which normally is at the top of the furnace, is brought to the side. The furnace is designed to take a 1,000-lb. charge and has been successfully used in melting cast iron, the time taken for a charge of this size being 1 hr., 40 min. OWE (22)

Plaster Patterns. *Foundry Trade Journal,* Vol. 45, Nov. 5, 1931, page 286.

A discussion of the advantages and disadvantages of plaster patterns. Provisions for drawing the pattern and the physical characteristics of the pattern material are described. 1 figure. OWE (22)

Critical Remarks Concerning the Testing of Molding Sand. (Kritische Betrachtungen zur Formsandprüfung.) Max Paschke & Eugen Schneider. *Die Giesserei,* Vol. 18, Dec. 25, 1931, pages 945-948.

The various factors which have to be taken into account in making samples for comparative tests of molding sands are discussed; such factors are mainly grain size, grain shape, colloid content, humidity, densification degree and chemical composition. It is shown that 3 ways are possible: tests can be made by the same height of the compressed samples, or by the same volumetric weight, or by the same power of compression. The possible errors in the compression of a sample in a test tube are explained. The factors determining the compressibility of a molding sand are briefly discussed; the method of calculating the compression energy is explained. Ha (22)

Aluminum Die Cast Molds (Aluminiumspritzgussformen). *Das Werkzeug (supplement to the Maschinenkonstrukteur-Betriebstechnik),* Vol. 7, June 25, 1931, pages 139-140.

The making of a die cast mold for motor hoods is described. MAB (22)

Recent Developments and Business Conditions in the U. S. A. Foundry Industry. Oliver Smalley. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 25-26.

The author introduces his subject with a concise description of business conditions in the U. S. A. and the plight of mass production foundries. Attention is then directed to technical developments of the past year and in particular to the Meehanite process. New Meehanite cupola irons include acid-resisting, abrasion-resisting, and oil-hardening mixtures. Some attention is devoted to improvements in the reclamation of core sand and to steel casting production. Malleable iron processes are also discussed, particularly the short-cycle anneal which has recently been developed. OWE (22)

Metallurgical Contributions to the Knowledge of the Phenomena in Cupola Furnaces (Metallurgische Beiträge zur Kenntnis der Kupolofenvorgänge). B. Osann, Jr. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Oct. 16, 1931, pages 809-818; Nov. 6, 1931, pages 859-866.

Exhaustive investigations of the operation of a cupola furnace are described. They were made to discover certain laws to which the metallurgical phenomena are subjected. The time of melting is considered particularly. It is measured by the temperature of the decending pig iron. It is stated that the coke charge influences the melting time considerably, irrespective of the conditions of the furnace and the other charges, because a high coke charge results in a high coke column above which the descending iron melts. The C content is always reduced to about the eutectic content when melting super-eutectic iron, but the course of melting has a certain influence. For very short melting times in the cupola furnace, the dissolving of the graphite is rather difficult but the oxidation of the graphite is enhanced during melting by the cupola furnace gases. The cast iron contains, therefore, little C. With increasing melting time, the conditions for the solution of the graphite become more favorable, so that the C content increases with the melting time. The completeness of the solution of the graphite increases with the melting time. For medium and long melting times, the C in the iron and the iron itself, are more able to react. This greater reacting ability results in stronger reactions between iron and slag and slag-forming constituents which changes the iron "secondarily." The secondarily changed iron differs from the unchanged iron melted in short melting times by lower contents of C and Mn, higher content of Si and S and finer structure. Finally, tests with small cupola furnaces are described which demonstrate the different behavior of gray and white iron at very short melting times. The process in an electric crucible furnace is also investigated. The principal result of the whole investigation is that the melting time in the operation of a cupola furnace must conform to the properties of the iron charge. Ha (22)

The Fundamentals of Brass Foundry Practice. R. R. Clarke. *Metal Industry,* London, Vol. 39, Aug. 21, 1931, pages 175-176.

Foundry practice for making Ni additions to brasses, for Monel metal, Ni-Ag, and 50-50 Cu-Ni alloys is given. PRK (22)

Coreprints. F. C. Edwards. *Foundry Trade Journal,* Vol. 45, Nov. 19, 1931, 313-314.

An article, accompanied by 12 diagrams, in which coreprint, design, and correct disposition of coreprints in molds of different designs are dealt with. OWE (22)

Molding a Blowing-Engine Piston in Loam. Hans Eckart. *Foundry Trade Journal,* Vol. 45, Dec. 10, 1931, pages 359-360.

Translation of an article on the above subject, which appeared in *Die Giesserei.* The article is accompanied by 16 diagrams which show very clearly the various processes involved in the production of this particular piston. OWE (22)

FURNACES & FUELS (23)

High-Frequency Induction Furnace Affords Heat Uniformity. H. C. Bigge. *Steel*, Vol. 88, May 7, 1931, pages 39-41, 57.

The progress in high frequency furnaces is described and the advantages in its uses for obtaining pure materials or materials of definite composition are pointed out. The construction and lining of furnaces and the compositions of products are described. Ha (23)

Industrial Furnaces for Gas. XI. Accessory Equipment. L. E. Biemiller. *American Gas Journal*, Vol. 135, Dec. 1931, pages 33-35.

Burner types and characteristics are classified. Theoretical considerations of systems of combustion are given along with a discussion of valve systems. Gas and air compressors, their characteristics and types are also discussed.

New Electric Furnaces. *Electrician*, Vol. 107, July 10, 1931, page 75.

A conveyor type equipment for the heat treatment of light metal disks is described and illustrated. The conveyor consists of 2 continuous bands of nichrome ribbon on which the metal disks are placed. Each strip or ribbon passes over grooved drums at either end. At the feed end both pulleys have independent counterweights so arranged that when the strip is hot and expands the slack is automatically taken up, keeping the strips always in tension. At the exit end of the furnace the 2 pulleys are driven by a ¼ hp. motor by means of chain and sprockets mounted on the pulley shaft of a variable speed gear permitting a rate of travel of conveyor and work adjustable between 12 to 20 in./min. The strip on its return passes under the furnace. Temperature is automatically controlled. WHB (23)

Annealing of Aluminum. *Electrician*, Vol. 106, May 8, 1931, page 690.

A large single track multi-car type electric annealing furnace with an effective hearth area 24 ft. × 7.5 ft. has been installed at the Dolgarrog Works of the Aluminum Corporation, Ltd. WHB (23)

Approximate Calculation of the Losses in the Cast Steel Ring of Soederberg-Electrodes. (Angenäherte Berechnung der Verluste im Stahlgussring bei Soederberg-Elektroden.) W. R. Blumer. *Elektrotechnische Zeitschrift*, Vol. 52, Dec. 24, 1931, page 1580.

The eddy current losses in a water-cooled steel ring electrode of an electric furnace for 70,000 amp. were calculated as 55 KW. To reduce this it is proposed to put a protective Cu layer on the ring. Ha (23)

Notes on Gas Producer Practice at Frodingham, together with General Observations. L. Cook. *Iron & Steel Industry*, Vol. 5, Oct. 1931, pages 23-26.

Abridged copy of a paper read at the Nov. 1931, meeting of the Lincolnshire Iron & Steel Institute. Steam jets have been replaced by centrifugal blowers in gas producers. The necessity for keeping the fires in good condition by balancing poor coal against good coal is stressed. The calculation of producer efficiency is discussed. CHL (23)

Prevention of Smoke in Metallurgical Operations. C. H. Desch. *Canadian Chemistry & Metallurgy*, Vol. 16, Jan. 1932, pages 17-18.

The ultimate solution of the smoke problem lies in electrical heating for steel and non-ferrous alloy industries. See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 49. WHB (23)

Italian Electrodes Made of Natural Graphite. Correspondence from F. Giolitti, Turin, Italy. *Metal Progress*, Vol. 21, Feb. 1932, pages 64-65.

The writer describes the solution of the problems of high electrical conductivity and slow combustibility in graphite electrodes. WLC (23)

Water-Cooled Furnaces and Firing Methods for Pulverized, Liquid and Gaseous Fuels. G. W. Glendon & Otto de Lorenzi (Combustion Engineering Corp.). *Combustion*, Vol. 3, Feb. 1932, pages 23-29.

Application of water-cooled furnace linings to replace those of refractory material has been one of the principal reasons for the success of modern high capacity steam generating units. Improvements in furnace design and construction as well as in methods of firing have been extraordinarily rapid. Various methods of firing are discussed, particularly corner firing, in which, burners are placed in 4 corners of the furnace and complete water-cooling is necessary. All 4 walls are covered with straight bare tubes with a minimum amount of refractory. DTR (23)

Development of the Calorific Power Determination of Solid Fuels. (Zur Entwicklung der Heizwertbestimmung fester Brennstoffe.) K. d'Huart. *Die Wärme*, Vol. 53, Apr. 26, 1930, pages 313-317.

Calorimetric determination and calculation of calorific power of solid fuels in Germany. Relationship between the combustion heat and the amount of air required for combustion. Critical review of French publications. EF (23)

Insulating Open-Hearth Furnaces. S. M. Jenkins. *Steel*, Vol. 88, Apr. 16, 1931, pages 35-38, 48.

The grade of insulating brick to use in open-hearth furnaces, how it should be installed, cost of insulating furnace equipment and the returns on the investment are described and discussed. Ha (23)

Measurement of Heat Value of Solid Fuels. (Heizwertmessung bei festen Brennstoffen.) Jos. Kroenert. *Archiv für Technisches Messen*, section V9214-1, 1931, page T14.

The heat value of solid fuels is calculated either indirectly from the chemical analysis or is determined directly in a calorimeter. The methods are described and the procedures explained. Ha (23)

Approximation Method for Calculating the Heat Exchange in Regenerators. (Näherungsverfahren zur Berechnung des Wärmeaustausches in Regeneratoren.) H. Hausen. *Zeitschrift für angewandte Mathematik und Mechanik*, Vol. 11, Apr. 1931, pages 105-114.

Graphical and numerical approximation methods are developed for the calculation of the time/temperature course in regenerators and the combined utilization of both methods is urged. EF (23)

Changing Trend of Power Distribution in the Steel Plant. S. S. Wales. *Proceedings Engineers' Society of Western Pennsylvania*, Vol. 47, Oct. 1931, pages 385-390.

The development of steam from by-product furnace gas (blast furnace, open-hearth, Bessemer, etc.) and the generation of electricity therefrom are discussed. For metallurgical purposes it is not as essential to clean the by-product gas as it is in the generation of power. By-product gas has a higher load-factor when used in the open hearth than in the power plant. This new trend of selling blast furnace gas to the public, and the steel plant buying its electricity is being developed more in Canada and Europe than in this country. Higher temperatures may be obtained from by-product coke gas than from blast furnace gas. WAT (23)

Measurements of the Rate of Flow of Liquid Metals in the Electric Furnace (Messungen der Strömungsgeschwindigkeit flüssigen Metalls im Elektroofen). M. Riepe & H. Ilberg. *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 2, Nov. 1931, pages 413-417.

The article considers the general and theoretical phases of the rate of flow of liquid metals in the electric furnace; describes the set-up and the basis for tests; gives the measurements obtained; and concludes that in an electric furnace the power used and the kind of current are of prime importance. The measurements were made by means of a throttle tube. The character of the current in the conduits of an electric furnace is determined by the existence of the electrodynamic power. The basis for calculating the amounts of metal put into circulation was determined with reference to the total friction of the liquids. The average velocity in the cross sectional area of a melt conduit diminished linearly with the distance of the area from the opening of the conduit at the bath. MAB (23)

Modern Constructions of Sheet Annealing Furnaces (Neuzeitliche Bauarten von Feinblechglühöfen). L. Pletsch. *Stahl und Eisen*, Vol. 51, Nov. 26, 1931, pages 1481-1483.

Some new constructions of German and English box annealing and continuous annealing furnaces are described. One furnace has bottom heating and a capacity of 80-92 tons of sheets with the boxes being moved on balls. Another furnace has an output of 110 tons of sheets. In the 2 English furnaces shown in sketches and used for normalizing automobile sheets and sheets for deep drawing purposes, the sheets are moved by arms without injuring the material. The arms subjected to high temperatures are made of heat resisting steel. GN (23)

Coreless Induction Furnace Larger; Lining Improved. E. F. Northrup. *Steel*, Vol. 88, June 4, 1931, pages 39-42.

The principles of the coreless induction furnace are explained and some new developments in its construction are described. Its uses for making high-grade and high-melting steels are discussed. Ha (23)

Anthracite Gas Reduces Scale Loss in Wire Processing. H. R. Simonds. *Steel*, Vol. 89, Sept. 17, 1931, pages 31-33.

Producer gas generated from anthracite is being used throughout the wire processing departments of the Stewart Hartshorn Co., Newark, N. J.; the equipment is described.

Temperature Distribution in Industrial Furnaces. Wirt S. Scott. *Electric Journal*, Vol. 28, Dec. 1931, pages 668-672.

A comprehensive investigation of electric and fuel furnaces showed wide variations between temperatures as recorded on control charts and those actually existing inside the furnaces in operation under normal conditions. The furnaces investigated were all in first class condition, but varying in age from 3 mo. to 10 yrs. An electric furnace can be made to operate with machine-like precision with close temperature control, whereas gas-fired furnaces are not evenly heated. WHB (23)

Modern Furnaces. Richard Rimbach. *Metals & Alloys*, Vol. 2, Sept. 1931, pages 158-164.

The author describes installations of heat treating and metallurgical furnaces to show the advances that have been made in operating efficiency, application of fuels, and quality of product by improved furnaces. WLC (23)

The Present State of the Electric Melting Furnace (Lo stato attuale dei forni elettrici fusori). O. Scarpa. *La Metallurgia Italiana*, Vol. 23, Oct. 1931, pages 909-941, 26 figures.

A general discussion of electric furnaces for non-ferrous melting, including various obsolete types is given. Furnaces for ferro alloys are also briefly discussed. HWG (23)

Experiments on the Occurrences of Combustion in a Flame of Pulverized Coal. (Versuche über die Verbrennungsvorgänge in einer Kohlenstaubflamme.) H. Schwiedessen. *Archiv für Eisenhüttenwesen*, Vol. 5, Dec. 1931, pages 291-298.

Report 157 of the Committee on Heat of the Verein deutscher Eisenhüttenleute. 4 references. Experiments were carried out in a pusher-type rolling mill furnace heated with pulverized coal. Temperature, gas content and fuel loss depend purely on the time of burning. In using only primary combustion air a true zone of degasification does not exist. The expulsion of volatile matter from the pulverized coal is extended through a rather long part of the combustion chamber since the volatilization is retarded by the external slagging of the grains of coal. However, the volatile matter burns immediately upon being expelled from the coal. The velocity of combustion is strongly affected by the concentration of O and the above-mentioned slagging. GN (23)

A Modern Foundry Core-Oven. (Un impianto moderno per la cottura delle anime in fonderia.) E. F. Russ. *La Metallurgia Italiana*, Vol. 24, Jan. 1932, pages 27-28.

An electric core oven 16 meters high has a conveyor system by which the cores are carried upward through the baking zone. The vertical arrangement of the oven saves floor space and avoids heating the core-room. HWG (23)

Soaking Pits without Checkers. J. B. Nealey. *Blast Furnace & Steel Plant*, Vol. 19, Nov. 1930, pages 1707-1708; *Steel*, Vol. 89, Aug. 27, 1931, pages 31-32.

A new type of soaking pit is described. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 24. Ha (23)

Outdoor Annealing Furnace 60 ft. long, 14 ft. wide. *Steel*, Vol. 89, Dec. 28, 1931, page 27.

A furnace used for relieving strain in large fusion welded pressure vessels and some constructional details are described. Ha (23)

One-Ton High-Frequency Induction Furnace. *Iron & Coal Trades Review*, Vol. 123, Dec. 11, 1931, page 908.

The furnace is operated by 500 cycle, 2000 volts, and has a capacity of 600 kw. The full charge of 1 ton can be melted in 1 hour. Curves of cost at different loads are given. Ha (23)

The Rotary Furnace "S.E.S.C.I." (Der Drehofen "S.E.S.C.I.") *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, pages 867-868.

A furnace consisting of an Fe sheet cylinder with truncated cones at the ends, lined completely with a refractory, tamped material, and heated by pulverized coal is made for continuous, uninterrupted operation in the manufacture of cast Fe and all kinds of steel. The economy is equal to or even better than that of the cupola furnace. Loss of metal is less than 1%. The lining will stand a temperature of 1800° C. The combustion air is preheated to 600° C. A melt (from cold furnace) for malleable Fe takes 3¼ hrs. and the third, 2 hrs., with less than 20 mins. between melts. 14 installations are already in operation in France, Italy, Belgium and England. Ha (23)

Gas versus Electricity in the Metallurgical Industry (Gas oder Elektrowärme in der metallverarbeitenden Industrie). D. I. Aigner. *Gas und Wasserfach*, Vol. 74, Aug. 29, 1931, pages 814-816.

The advantages and disadvantages of generating heat for metallurgical purposes from gas and from electricity are considered from a technical and economical stand-point. The author is, apparently, in favor of heating metallurgical furnaces by gas and carries out a detailed economical calculation in the case of a bath for hardening drills. The superiority of electric heating claimed for a set of 8 annealing furnaces (total output 30 tons/day) is critically discussed and passing mention is made of furnaces for melting Zn, Sn, Al, and Cu-alloys for the enamelling process. EF (23)

Appearance of Oil in Blast Furnace Gas Lines. (Auftreten von Oel in Hochofengas-Leitungen). Herbert A. Bahr & Vitus Jessen. (Völklingen, Saar). *Stahl und Eisen*, Vol. 52, Jan. 7, 1932, pages 13-15.

Blast furnace gas from the Völklingen blast furnaces contained a mist of oil. A part of the charge was rolling mill scale carrying 0.13% oil. The distillation temperature, specific gravity and solubility of the oil in the blast furnace gas were similar to those of the oil in the mill scale. The oil in the gas was absorbed by a fine dust filter and there was a possibility that oil had passed from the dry gas purification system directly into the pure gas lines. The possibility for formation of oil in the blast furnace by the Fischer-Tropsch synthesis was discussed and a certain probability was seen for this condition from the CH_4 formation in the furnace. GN+DTR (23)

The Distribution of the Electrical Field in the Arcs of Electric Furnaces with Interrupted Operation for the Melting of Steel. (Ueber die Verteilung des elektrischen Feldes in den Lichtbögen elektrischer Oefen mit unterbrochenem Betrieb zur Erschmelzung von Stahl.) G. Agostinelli. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Dec. 4, 1931, page 923.

A method is described for determining from the physical properties of the electric arc the distribution of the potential and of the electric field in all positions of the electrodes by means of an elliptical coördinate system. The influence of the magnetic field in a furnace with 3 electrodes was investigated with an oscillograph. Ha (23)

The Slag-Tap Furnace for Burning Pulverized Coal. E. G. Bailey & R. M. Hardgrove. *Rolling Mill Journal*, Vol. 5, Dec. 1931, pages 787-790.

The great importance of the ash content of a fuel and the fusing temperature of the ash, whether higher or lower than the furnace temperature, and the attending difficulties in the latter case, are thoroughly discussed. The different systems of ash removal from the furnace are described. The advantages of the slag-tap furnace are mainly complete combustion of the coal, smaller building height; and simple removal of ash by letting it flow into a sluice. This type of furnace can be used successfully with all coals where the ash has a fusing temperature below 2500° F. Low grade coals can be burnt with better efficiency. Ha (23)

The Oil-Cupola, System Marx. (Der Öl-Kupolofen, System Marx) E. Becker. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Jan. 17, 1932, pages 29-30.

A new cupola with oil heating is described and compared with the Wüst furnace. It offers the following metallurgical advantages: The S content of the melt can be kept very low, since the oil used contains little S, the melt can be easily superheated, thus securing a fine grained structure; the flame can be properly regulated and the waste of metal through oxidation is small. The cupola is fit for the production of high test cast Fe. The oil consumption is about 6.5% (by weight) of the charge; the heat efficiency amounts to about 43% which is by about 80% better than that of the coke-fired cupola. GN (23)

Recent Developments in British Blast Furnace Coke Technology. Edgar C. Evans. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 83-86.

The work done by research committees in determining standards by which coke may be evaluated is discussed. Shatter tests and measures of reactivity have been suggested and general recommendations made governing the manufacture of coke. CHL (23)

Air-Gas Proportioners Serve Bolt and Rivet Furnaces. F. J. Evans. *Steel*, Vol. 89, Sept. 10, 1931, pages 46-50.

An installation of air-gas proportioners in a bolt and rivet factory is described. Ha (23)

The Selection of Coke for Foundry Purposes. (Koksauswahl für Giessereizwecke.) Otto Huppert. *Giesserei Zeitung*, Vol. 27, Jan. 15, 1930, pages 35-37.

Coke with low H_2O, ash and S content and high strength are desirable. For cupola coke, low activity (velocity of reducing CO_2 to CO) is debatable. This activity is attributed to the unsaturated amorphous C atoms. When activity is desired the graphitization caused by coking at too high a temperature is to be avoided. (23)

REFRACTORIES & FURNACE MATERIALS (24)

New Developments in Unburned Magnesite Brick for Metallurgical Industry. A. E. Fitzgerald (Condensed by M. F. Behar) *Metals & Alloys*, Vol. 3, Jan. 1932, page 25.

The use of higher pressure, proper size mixtures and a colloid bond have produced an unburned magnesite brick of satisfactory strength without excessive shrinkage under service conditions. Properties and applications are discussed. WLC (24)

Properties of Silica Brick Manufactured from Sharon Conglomerate. C. L. Frederick, Jr. *Journal American Ceramic Society*, Vol. 15, Jan. 1932, pages 61-67.

New developments in the field of silicate refractories include greatly improved refractoriness and a high development of desirable qualities in silica refractories manufactured from Sharon conglomerate. The nature of silica refractories in general is discussed and a résumé of materials utilized in the manufacture of silica brick in the United States is given. Several illustrations of this new refractory are included, as well as test data. WAT (24)

The Alumino-Silicate Refractories. G. A. Bole (Ohio State University). *Metals & Alloys*, Vol. 3, Jan. 1932, pages 15-22.

The author's discussion of alumino-silicate refractories is prefaced with a consideration of the equilibrium diagrams of SiO_2-Al_2O_3 and SiO_2-Al_2O_3-CaO. The simpler the phase structure of a refractory the greater resistance to heat, providing of course that the individual phases are themselves resistant. Increase in the number of phases increases the tendency to form eutectics of low melting point. Mullite is the only aluminum silicate stable at high temperatures, $3Al_2O_3 \cdot 2SiO_2$. All aluminum silicate minerals invert to mullite on heating and sweat out a highly siliceous material at 1545° C. Sillimanite, andalusite and cyanite are minerals all of composition $Al_2O_3SiO_2$ and invert to mullite on heating and sweat at 1545° C. Minerals of higher Al_2O_3 than 56% melt at 1810° C. to liquid and corundum. The changes in firing various alumino-silicate minerals, sillimanite, diaspore, and kaolin are described and discussed. The properties of various commercial grades of mullite, sillimanite, andalusite, kaolin, and diaspore refractories are described and their applications discussed. WLC (24)

Refractories for Blast Furnaces and Hot Blast Stoves. W. G. Girling. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 95-96.

The author discusses the trend toward machine-made brick and presents the results of observations of foundrymen on the best chemical analysis for brick in the sections of the blast furnace. A typical analysis for machine-made brick is given as follows, silica 55.30, alumina 37.09, ferric oxide 2.29, lime 0.62, magnesia 0.83, alkali 1.98, and titanium oxide 1.72%. The refractoriness was found to be cones 31-32, 1700° C., the true specific gravity to be 2.52%, and the cold crushing strength to be 5,846 lbs./in.^{2} CHL (24)

Effect of Firing at 1500° C. on the Porosity and Specific Gravity of Quartzites. Sanford S. Cole. *Journal American Ceramic Society*, Vol. 15, Feb. 1932, pages 87-95.

Quartzites from the various deposits being commercially utilized for the manufacture of silica brick in the United States, Canada and Europe were tested for porosity and apparent specific gravity before and after firing at 1500° C. for 2 hours. Petrographic examination was made of several of the raw quartzites, and the differences in crystalline structure are shown by photomicrographs. The rate of conversion of the quartz was not constant for the quartzites reported. The porosity after firing varied from 2 to 30% and the apparent specific gravity varied from 2.30 to 2.44. A fine-grained quartzite tends to give lower porosity after firing. WAT (24)

Bonding Magnesite Linings for Steel Melting Furnaces without Use of Iron Oxide. Louis Jordan (U. S. Bureau of Standards). *Metals & Alloys*, Vol. 3, Jan. 1932, pages 22-24.

The author describes experiments in the preparation of a basic lining in a rocking type indirect arc furnace. The use of iron oxide as a bond in furnace bottoms often results in weakening of the bottom due to solution of the bond from the magnesite by deoxidized metal in the bath. A bond of water-ground magnesite was used with electrical sintered magnesite and gave excellent results under rather severe conditions of overheating and intermittent operation. WLC (24)

Refractory Materials. Alexander H. Hayes. *World Power*, Vol. 16, Dec. 1931, pages 450-454.

The variable factors governing the choice of refractory materials, and the most important materials (silicas and fireclays, high alumina refractories, chromite, dolomite, magnesite, and silicon carbide) are dealt with in a general manner. Metallurgy has adopted, as result of experience, certain general rules for the employment of different classes of refractories. It is unfortunate, from the users standpoint, that the selection of refractory materials cannot be subjected to rigid specifications. Since a primary requirement for refractory materials is the ultimate economic value of the refractory, it is practically a necessity in every case to study the local conditions in relation to the physical and mechanical characteristics of different materials available, before the most economical refractory can be chosen. The choice inevitably resolves itself into a compromise between cost and the maximum desirable properties. WAT (24)

Progress in the Field of Refractories. Annual Report from October 1929 to September 1930 (Fortschritte auf dem Gebiete der feuerfesten Baustoffe. Jahresübersicht Oktober 1929 bis September 1930). E. H. Schulz, F. Hartmann & A. Kanz. *Stahl und Eisen*, Vol. 51, Dec. 17, 1931, pages 1569-1573; Dec. 24, 1931, pages 1595-1599.

The report reviews 109 papers on refractories dealing with (1) raw materials, preparation and processing; (2) furnaces and operation; (3) testing methods and equipment; (4) properties; (5) quality requirements and specifications; (6) special refractories and newly developed materials; (7) cement, concrete; (8) literature. GN (24)

GASES IN METALS (25)

The Occurrence of Small Quantities of Gases and Oxides in Aluminum and Aluminum Alloys. (Ueber das Auftreten kleiner Mengen von Gasen und Oxyden im Aluminium und in Aluminiumlegierungen.) R. Sterner-Rainer. *Zeitschrift für Metallkunde*, Vol. 23, Oct. 1931, pages 274-282.

Includes discussion. The work of Czochralski, and Claus on the solution of gases in molten Al alloys and the formation of oxides is discussed. The gas content of molten Al alloys is best determined by melting in a vacuum and by planiometric study of the sectioned ingot. Oxides are determined by weighing Al_2O_3 after solution in an acid. The absorption of gases and the formation of oxides cannot be wholly prevented, but can be reduced by holding the molten alloy for a period just above the melting point (710°-730°C.) and by bubbling gases through the molten metal. N_2 and Cl_2 are helpful. Dissociating chlorides (zinc chloride, silicon trichloride, chlorides of Fe, Sn, and Ti). Better results have been obtained with mixtures of various easily decomposed chlorides containing bifluorides; this mixture, containing also siliceous earth, asbestos wool, coal dust, etc., was worked into a paste and pressed down to the bottom of the metal bath. Followed by a lengthy discussion. RFM (25)

The Sorption of Hydrogen on Copper. Part 1. Adsorption and the Heat of Adsorption. Part 2. Rate of Solution. A. F. H. Ward. *Proceedings Royal Society*, Vol. 133A, Oct. 1931, pages 506-535.

The sorption and heats of adsorption of H on activated copper catalysts have been measured at 25° C. for successive additions of gas. The instantaneous adsorption on the surface was followed by solution which occurred very gradually. The difference allowed these processes to be separated and the true adsorption isotherm found. This was exactly reversible on decreasing the pressure. After correcting for gas in solution and the heat of combustion of the gas, the heats of adsorption and desorption were found to be independent of the concentration of the gas on the surface, but decreased after each baking of the copper till they reached a final value of about 9000 cal. per gram-molecule. The isotherms were not affected by baking below the temperature of preparation of the copper (150° C.), but after sintering above this temperature the amount of gas adsorbed was decreased. The effect of points of high energy on the activity of the whole surface is discussed. The adsorption of H on Cu and the rates of diffusion into the interior of the metal have been measured at various pressures over a temperature range 25°-200° C. It is shown that for any temperature the rate of diffusion into the metal is proportional to the amount of gas adsorbed on the surface. The rate of diffusion is, therefore, related to the gas pressure by the same form of equation as the adsorption isotherm. The variation of the rate of diffusion with temperature gives an energy of activation for the diffusion process of 14,100 cals./gram-molecule. The previously accepted theory that the diffusing molecules are split up into atoms, since diffusion rates are proportional to the square root of the pressure, is criticized and shown to be improbable. Calculations from figures of other workers are in agreement with the theory developed here. Reasons are given why it is probable that grain boundary diffusion is occurring rather than lattice diffusion. WAT (25)

Modern Methods for the Determination of Gases in Steel. B. Jones. *Metallurgist*, Oct. 1930, pages 151-152.

An excellent summary of 39 references on the determination of O, N and H in iron and steel. VVK (25)

Oxygen, Nitrogen, and Hydrogen as Constituents in Metals. H. C. Vacher. *Journal of Chemical Education*, Vol. 9, Jan. 1932, pages 47-54.

Many metals while in the liquid state, dissolve more O, N or H than can be retained in solution in the solid metal. This results in the formation of gas pockets or non-metallic inclusions in the solid metal. Methods are developed which permit the determination of the amounts of these elements actually dissolved in the metal and those contained in the inclusions. The effects of gas pockets and non-metallic inclusions on the mechanical properties are quite familiar. The effects of relatively small amounts of the 3 gases which may exist in solution in the apparently sound material are not yet definitely known and have been recognized only recently. The methods which permit an estimation of the amount and the manner in which O may exist in plain C steels are vacuum fusion, H reduction and residue methods. A list of selected bibliography on gases in metals is added. Ha (25)

Oxygen films on Tungsten. I. A Study of Stability by Means of Electron Emission in Presence of Caesium Vapor. I. Langmuir & D. S. Villars. *Journal American Chemical Society*, Vol. 53, Feb. 1931, pages 486-497.

A method is presented of studying the rate of loss of oxygen from an adsorbed film on tungsten, as well as of detecting its presence in a gas. This consists in observing its effect on the electron emission of a tungsten filament, sensitized by the presence of minute traces of cesium vapor. Under properly chosen conditions a monatomic oxygen film makes its presence known by increasing the emission a millionfold. MEH (25)

Determination of the Energy Levels of Adsorbed Hydrogen and Oxygen by the Method of Electron Impacts (Bestimmung der energetischen Niveaus des absorbierten Wasserstoffs und Sauerstoffs nach dem Verfahren des Elektronenstosses). N. I. Kobosew & W. L. Anochin (Moskow State University). *Zeitschrift für physikalische Chemie*, Abt. B, Vol. 13, June 1931, pages 18-62.

The rate of release of adsorbed H_2 or O_2 from metallic surfaces as a function of the potential drop through which bombarding elements have passed was used to study various characteristics of adsorbed H_2 and O_2. The measured release potentials measured on Pd, Pt, Au, Zn and Pb directly confirm the over-voltage theory of Kobozew and Nekassov. EF (25)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Effect of Copper in Cast Iron. Correspondence from C. G. Williams (Barker Machine Works & Tool Co.). *Metal Progress*, Vol. 20, Nov. 1931, pages 81-82.

The writer tells of interesting experience with copper in Ni-Cr cast iron as increasing the resistance to corrosion with less Ni and Cr and giving very excellent wear-resistance. WLC (27)

Nickel in Non-Ferrous Metals (Nickel in Nichteisenmetallen). H. Kalpers. *Dinglers Polytechnisches Journal*, Vol. 345, Jan. 1930, pages 3-6.

The addition of Ni to brass, bronze and Cu-alloys is discussed at length. The chemical analyses, physical properties and commercial significance are stressed. EF (27)

Alloyed Castings. (Legierter Guss.) E. Kothny. *Giesserei-Zeitung*, Vol. 27, June 1930, pages 291-300, 323-327.

A review of the effects of Ni, Cr, Ni-Cr, Ti, Al, B, Ce, Co, Cu, W, Mo, Va and Zr upon the constitution and the physical and chemical properties of gray, chilled and malleable Fe castings. A bibliography is appended. (27)

The Effect of Manganese in Cast Iron. (Die Wirkung des Mangans im Gusseisen.) K. Lehmann. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Jan. 10, 1932, pages 18-20; Jan. 17, 1932, pages 31-32.

General survey as to how Mn affects the properties of cast iron. GN (27)

The Influence of Carbon on the Structure of Austenitic Nickel-Chromium Alloys. (Der Einfluss des Kohlenstoffes auf das Gefüge der austenitischen Nickel-Chromlegierungen.) E. R. Thews. *Die Metallbörse*, Vol. 21, Jan. 3, 1931, pages 6-7; Jan. 31, 1931, pages 197-198.

The influence of C in binary Cr and Ni alloys and in 18/8 on the metallographic structure is summarized, the influence of cold work is discussed and the proper heat treatment of austenitic Cr-Ni steels is summed up. The influence of the carbon precipitations on the chemical and physical properties of 18/8 is considered. EF (27)

A Study of the Influence of Iron in Duralumin. (Eine Untersuchung über den Einfluss des Eisens in Duralumin.) W. Kroenig. *Zeitschrift für Metallkunde*, Vol. 23, Sept. 1931, pages 245-249.

5 alloys were studied of the compositions 4.58 to 4.70% Cu, 0.45 to 0.50% Mg, 0.56-0.65% Mn, 0.25-0.33% Si, with 0.22, 0.52, 0.93, 1.10, 1.50% Fe respectively. It is shown that increasing Fe diminishes the tensile strength and hardness, and that this difference between Fe-rich and Fe-poor alloys is increased by increase in quenching temperature. Duralumin with Fe has a lower tensile strength and hardness immediately after quenching than duralumin low in Fe, owing presumably to diminution in solid solubility of $CuAl_2$. The increase in strength on aging at room temperature is constant with increasing Fe-content; the hardness however increases more in an alloy with 0.22% Fe than in an alloy with 1.5% Fe. The hardness of thoroughly annealed duralumin with different Fe-contents approaches a constant value the more thorough the annealing. Up to 0.9% Fe the iron is found in the form of an eutectic; at higher Fe-compositions it occurs as primary crystals. It is shown that the $CuAl_2$ is restrained from solution by the eutectiferous Fe, thus affecting the mechancial properties of duralumin containing Fe. RFM (27)

Various Factors Affect Growth of Gray Cast Iron. W. E. Remmers. *Steel*, Vol. 88, Mar. 5, 1931, page 63.

A brief description of studies made with alloying elements; Si, Al, Ti and Ni tend to increase growth, Cr and Mn tend to decrease it. Ha (27)

Sulphur and Phosphorus in Quality Steels. Correspondence from B. F. Shepherd (Ingersoll Rand Co.). *Metal Progress*, Vol. 20, Nov. 1931, pages 78-79.

The writer gives Swedish and French ideas about these 2 elements. WLC (27)

The Effect of Small Additions of Aluminum to Gray Cast Iron (Der Einfluss kleiner Zusätze von Aluminium zu grauem Gusseisen). G. Sirovich. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, page 867.

An addition of up to 1% Al increases the fluidity and the disintegration of the cementite in favor of a better graphitization. This is advantageous for producing thin-walled castings and a better machineability. An increase of more than 1% is useless. Ha (27)

Influence of Magnesium Oxide on Reduction, Oxidation, and Carbonization Reactions of Iron. (Der Einfluss des Magnesiumoxyds auf die Reduktions-, Oxydations- und Kohlungsvorgänge beim Eisen). Josef Klärding. *Stahl und Eisen*, Vol. 52, Jan. 7, 1932, page 15.

Reactions of mixtures of Fe_2O_3 and MgO in proportions of 2:1, 1:1, and 1:10, respectively, with cementite at 650° C. and those of Fe and MgO and Al_2O_3 in varying proportions with CO at 650° C., are shown on equilibrium diagrams, as displacements from pure system Fe-C-O. With increasing magnesia and alumina, reaction goes in the direction of higher CO formation, although the writer points out that at 650° the diffusion was only slight, and the exact effect of the MgO could not be determined. GN + DTR (27)

Vanadium in Steel Castings. *Foundry Trade Journal*, Vol. 45, Dec. 10, 1931, pages 364, 368.

An article based on information supplied by High-Speed Steel Alloys, Limited, of Widnes, Lancaster, Eng. The characteristics of V steel castings are described. Following this description, the Ni-V steels, Mn-V steels and Cr-V steels are dealt with in order. The situations in which these steels are finding use are discussed, and in conclusion the relatively small cost of V steels as compared with steels free from this element is pointed out. OWE (27)

The Various Elements in Cast Iron. Gilbert S. Schaller. *Western Machinery World*, Vol. 22, Sept. 1931, pages 428-431.

Discusses briefly the effects and actions of C, Si, S, Mn and P, as well as the forms which C assumes in cast iron. WAT (27)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Apparatus for Determination of Thermal Expansion of Solid Bodies at High Temperatures. (Ueber einen Apparat zur Bestimmung der Thermischen Ausdehnung fester Körper bei hohen Temperaturen). H. Gerdien & W. Jubitz. *Zeitschrift für technische Physik,* Vol. 10, 1929, pages 614-620.

Detail sketches of a thermal expansion outfit in which water-cooled contacts are not kept touching the specimen through the run, but are periodically brought up against the specimen, and the pressure under which contact is made is measured by electrical means. The contact only lasts 1/10 sec. in making a measurement. The apparatus is very complicated and for details the original must be consulted. Calibration is by means of a silver specimen. The specimens are 200 mm. long. The expansion coefficient of Ni from 20° to 1000° C., determined with the apparatus, is 16.76×10^{-6} and that of soft iron from 20° to 720° C., 15.12×10^{-6}.

Permanent Growth of Gray Iron on Heating. (L'ingrossamento permanente della ghisa grigia per effetto del calore.) G. Calbiani. *La Metallurgia Italiana,* Vol. 23, Dec. 1931, pages 1135-1145; *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 6, 1931, page 866.

Gray iron of 3.25% total C, 1.34% Si, 0.41% Mn, 0.07% P, 0.13% S was cast into step castings, with steps 50, 30, 15 and 5 mm. high by 50 mm. (each step, 200 mm. total length) by 80 mm. and into bars of 32 and 47 mm. diameter. The step castings were not machined. The bars were machined into cylinders of various diameters. 3 sets of specimens were heated, respectively to 650°, 750° and 850° C. for 8 hrs.; the heating was repeated 10 times. Growth was measured and compared with the ratio of surface to volume of the specimen. The greater is the ratio of surface to volume, the greater the growth. The percentage increase in length on specimens with a ratio of 0.93 was: 650° C., 0.42%; 750° C., 0.65%; 850° C., 1.38%; while at the other extreme, with a ratio of 4.70, the figures were: 650° C., 1.86%; 750° C., 2.40%; 850° C., 4.54%. The complete data are tabulated and micrographs of the structure shown. Contains 35 figures, 11 references. Ha + HWG (29)

Use of Metals at High Temperatures. H. A. DeFries. *Conference on Metals & Alloys, Case School of Applied Science, Cleveland, Ohio,* Paper No. 12, Nov. 1931. Mimeographed. 7 pages.

A general resumé. Plain 0.20% C steel is usable to around 900° F.; its load for a creep rate of 1% in 100,000 hrs. is 7,800 lbs./in.² A 5% Cr steel has only 5,100 lbs./in.² at 900° F., but is more resistant to scaling. One with 12% Cr and 0.10% C can be used to 1100° F., where it gives 4,000 lbs./in.² The 18 Cr, 8 Ni alloy with 0.07% C maximum can be used to 1300° F. where it has 3,000 lbs./in.² Above that temperature brittle breaks may occur without deformation as a warning. Other compositions are briefly discussed.

The Exact Measurement of the Specific Heat of Osmium and Rhodium between 0° and 1625° C. F. M. Jaeger & E. Rosenbohm. (In English.) *Proceedings, Koninklijke Akademie van Wetenschappen te Amsterdam,* Vol. 34, No. 1, 1931, pages 85-99.

The atomic heat at constant pressure is, for Os, 5.9152 + 0.0009019t. The atomic heat at constant pressure for Rh rises from 6.064 at 0° C. to 8.354 at 1200° C. and then falls to about 7.60 at 1625° C. No corresponding anomaly was found in the thermoelectric force against Pt. There is an inflection in temperature-electrical resistance curve for Rh at 1000°-1100° C., but no sudden break. While electrolytically deposited Rh or that obtained by reduction with hydrazine sulphate contains two modifications α and β, the α disappearing above 1400° C., the shape of the specific heat-temperature curve is not accounted for by transformation of allotropic modifications. HWG (29)

A Method for the Measurement of the Temperature Coefficient of Heat Conductivity of Materials (Sur une méthode de measure du coefficient de conductibilité calorifique des matériaux). L. Joly. *Comptes Rendus,* Vol. 192, Mar. 30, 1931, pages 797-799.

A discussion of the theory underlying the measurement of heat conductivity in materials, followed by a description of methods adopted by le Comité du Génie de l'Office national des Inventions for making such determinations.

The Performance of Cast Carbon and Low-Alloy Steels in High- and Low-Temperature Service. R. A. Bull (Electric Steel Founders' Research Group). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 394-435.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 191. In the discussion it is pointed out that imperfect castings have probably been the greatest single cause of trouble in the service of cast furnace parts. The superiority of cast materials over wrought materials of the same composition for elevated temperature service is also noted. It appears that the outstanding need in creep testing at the present time is a determination of the effect of the various alloying elements upon the recrystallization range of iron. At temperatures below the recrystallization temperatures, stresses of appreciable magnitude may be withstood without continuous deformation or creep, at least within the sensitivity of the measuring apparatus, employed, while above, continuous creep is produced by any stress regardless of its magnitude. Within the recrystallization range there appears to be a direct relationship between a definite rate of creep and the proportional limit as determined in the short-time tensile test. Emphasis is placed on the significance of design in elevated temperature serviceability. There is much need of coöperation between designers and manufacturers. A review of existing data makes it appear that cast Cr-Mo, Ni-Cr-Mo, C-Mo and Mo-Mn steels give promise of being superior alloys for elevated temperature high pressure service under 1000° F. WAT (29)

Properties of Bearing Metals at Normal and Elevated Temperatures. E. R. Darby (Federal Mogul Corp.) *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 316-339.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 191. In the discussion it is pointed out that the statement made in the paper, relative to white metal alloys, namely that Pb-base alloys are generally weaker and softer at elevated temperatures than are Sn-base alloys, is not entirely supported by the experimental data included, nor is it in agreement with results of recent determinations at the U. S. Bureau of Standards. Determinations of the resistance to pounding and of the hardness of some white metal bearing alloys indicate that the Brinell hardness of the Pb-base alloys containing 5 % or more of Sn equals or exceeds that of the Sn-base alloys up to 150° C. The hardness of the Pb-base alloys, excepting an alkali-hardened Pb alloy, and of a Sn-base alloy all fell within a narrow range (about 4 to 7 Brinell) at 200° C. The data indicate that the Pb-base alloys containing upwards of 2 % Sn are more resistant to pounding at 150° C. than the tin-base alloys. The Pb-base alloys containing 5 % or more of Sn excel the Sn-base alloy in this same respect at 200° C. Notched-bar Izod impact tests at elevated temperatures substantiate the conclusions drawn in the paper that the Pb-base alloys are weaker than the Sn-base metals. Considerable additional data are presented. In further discussion, the Magnus Company states that the German alloy "Bahnmetall' or "railroad metal" containing about 0.6 % Ca, 0.6 Na, 0.03 Li, 0.10 Al and balance Pb practically replaced Pb- and Sn-base babbitt metals in Germany during the World War. In recent years its use has been limited on account of the extreme care necessary in melting. A modification of this alloy, however, is now available commercially. WAT (29)

Industrial Gas Research in Scaling of Steel at Heat-Treating Temperatures. Clair Upthegrove. *Western Machinery World,* Vol. 22, Oct. 1931, pages 442-443.

Tests were carried out at the University of Michigan under the auspices of the American Gas Association. The experimental procedure was identical with that used by Jominy and Murphy for work at forging temperatures (*Transactions A. S. S. T.,* Vol. 18, 1930, pages 19-57). The steel tested was S. A. E. 1015. Tests made with increasing time show, as would normally be expected, that the amount of scaling increases with the length of time that the steel is exposed to the scaling medium. The rate of scaling, however, decreases with increasing time and with atmospheres of O and dry air, and at a temperature of 1520° F., the curve showing the change in rate is of the parabolic type. At the same temperature and with an atmosphere of carbon dioxide the curve showing the increase in the amount of scale appears to be a straight line. WAT (29)

The Creep of Materials and Creep Stresses. Jas. Cunningham. *Steam Engineer,* Vol. 1, Jan., 1932, pages 162-163.

General discussion. AHE (29)

The Trend of Progress in Great Britain on the Engineering Use of Metals at Elevated Temperatures. R. W. Bailey (Metropolitan-Vickers), J. H. Dickenson (English Steel Corporation), N. P. Inglis & J. L. Pearson (Synthetic Ammonia and Nitrates). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 218-244.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 192. In the discussion it is suggested that when very minute plastic changes are being considered in design work, instead of taking "rate of creep," it would be more precise to use "total creep." Steels at temperatures below 1000° F. have a tendency to show comparatively high primary and small secondary flow at reasonable design stresses. In many cases after the initial creep appreciably small further creep takes place. The primary creep can in such cases be regarded as the total creep. In all designs requiring a high stability of dimensions stress analyses should therefore be made on a basis of total creep. The University of Michigan presents data on elevated temperature torsion tests of tube materials. The loading apparatus and measuring equipment used in making these tests are shown. A mathematical analysis which, in a modified form is shown in the formula, expresses the relationship between shear stress, f in lbs./in.^{2}, shear creep rate Φ in strain/hour, the temperature Θ in ° F., and e, the base of Napierian logarithms.

$$f = \frac{8.7 \times 10^6}{e^{0.006(-)}} \left(\frac{\Phi}{2}\right) 0.15$$

Another discusser states that up to about 800° F. the characteristics of tension and torsion are almost identical, but beyond 800° F. they differ quite widely. In the author's closure, it is suggested that this departure in agreement above 800° F. is due to a difference in the rates of straining. WAT (29)

The Electrical Conditions of Hot Surfaces During the Absorption of Gases—Carbon and Copper Surfaces at Temperatures up to 850° C. G. I. Finch & J. C. Stimson. *Proceedings Royal Society,* Vol. 132, 1931, pages 192-199.

The electrical conditions of a carbon rod and a Cu sheet have been studied at temperatures up to 850° C. in vacuo and in contact with various gases. The carbon rod does not exhibit constant and reproducible surface potential values until after the initial evolution of occluded gases has ceased. It is suggested that the emission of gas results in structural changes occurring in the surface and that such gas is probably chemically bound by the surface. The Cu sheet is not "normalized" until some time after the slight initial gas evolution has ceased so that in this case sintering is probably taking place. Copper oxide completely blankets the surface of the metal, so that it does not exhibit a surface potential either in a vacuo or in contact with oxygen. Evidence is obtained that the charge acquired by any of the surfaces examined tend to approach zero as the "normalization" temperature is increased. It is found that at 850° C. the values of the surface potentials on the metal surfaces fall into three distinct groups, (1) oxygen, (2) vacuo, nitrogen, argon, and carbonic oxide, and (3) hydrogen. At this temperature the specific effect of the surface potential appears to be very much reduced, and the value obtained is largely determined by the nature of the gas with which hot surface is in contact. WAT (29)

Needs of the Oil Industry for Metals at High Temperatures. E. S. Dixon (Texas Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 66-99.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 191. In the discussion it was pointed out that it would be worth while to obtain further replies to Dixon's questionnaire and amplification of those received. Attention is directed to the fact that the stresses producing creep in cylindrical vessels are not entirely simple tension stresses. Thermal conductivity, expansion and fatigue are important and should be considered simultaneously with creep. Many of the replies to the questionnaire were uncertain of the actual operating temperatures. A greater effort should be made to obtain such data. A summary of the annual steel tonnage used in the United States in the oil refining industry on the basis of a normal year, as compared with the year 1931, is presented. Another discusser states in order to develop maximum resistance to corrosion the 18-8 Cr-Ni steel should be heat treated. Experience has shown the 24-12 Cr-Ni alloy to be more resistant to sulphur attack. Of the thousands of tubes of the low-carbon 18-8 Cr-Ni alloy in service there have been but approximately 12 failures. These have been traced to overheating as result of lack of sufficient temperature control. The Standard Oil Company of Indiana considers pressure, temperature and corrosion the most important factors to be considered. Thermal expansion and a high degree of ductility are of less importance. At present, pressures do not exceed 1500 lbs. and metal temperatures should not have to operate above 1250° F. This company does not feel that a warning before failure is a necessary qualification of the metal. The Calorizing Company presents data taken from a typical still showing the life of tubes at elevated temperatures. It is shown that it is the relatively short period at higher temperature at the end of the cycle that determines the life of the tube more than the normal operating temperature. The tubes operate for 90% of the time in a stress range which would give from 10,000 to 100,000 hours of life with only 1% elongation. Data is also presented on tensile strength to 1800° F on an alloy containing not less than 20% Cr, 8 Ni, not over 1.2% C, and Al from 0.5 to 8.0% depending on the type of casting and service. This material holds its room temperature strength up to 1200° F. and is highly resistant to sulphur attack. Still another discusser states that their crude oil is not corrosive and therefore plain C steels are satisfactory provided necessary operating precautions are taken. The problem is very complex and each refiner must treat his needs separately. WAT (29)

Steam Turbine Materials for High Temperatures. R. C. Allen (Westinghouse Electric & Mfg. Co.). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 30-48.

For abstract of paper see *Metals & Alloys,* Vol. 2, Dec. 1931, page 324. In the discussion it is pointed out that in tensile creep tests of carbon steels if the temperature is increased from 750° to 850° F. the stress should be lowered 60% of the previous value in order to keep the creep rate unchanged. Data on creep tests in tension are not always entirely satisfactory; creep tests in torsion are necessary. For satisfactory design work at high temperatures, formulas are needed which will take care of creep of the material and give the dimensions of parts as a function of the allowable creep. Similar formulas are needed for bending and torsion. In this manner rational stress calculation taking creep into account will result in more economical machine structures. Another discusser states that the strength of silver solders at elevated temperatures is not important in general use. However, research work carried out by Handy & Harman on the strength of silver-soldered butt joints on stainless steel made with an oxy-acetylene torch showed an average breaking strength on 12 test bars of 70,000 lbs./in.^{2} at room temperature. 12 other specimens gave an average value of 13,400 lbs./in.^{2} at 1000° F. If silver-soldered joints are likely to be subjected to elevated temperature, careful tests should be made under conditions approximating the actual service if possible. WAT (29)

Engineering Requirements in the Automotive Industry for Metals Operating at High Temperatures. A. L. Boegehold (General Motors Corp.) & J. B. Johnson (Army Air Corps). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 169-200.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 192. In the discussion it is stated that the use of a cast iron containing Al which can be nitrided to give very hard surfaces has been neglected in making cylinder blocks, as well as pistons. Cr plating the bearing surfaces of crankshafts, pistons and the like should materially lengthen the life of such parts. The greater cooling rate offered by Al pistons reduces the effective pressure so that the power developed may not be appreciably increased by the higher compression ratio allowable with Al pistons. Electroplating about a 0.001 inch thickness of Sn on the skirt of cast iron pistons is a recent innovation in piston practice and is claimed to offer improved car performance. It is strongly emphasized that over 0.5% Pb in Babbitt is very detrimental at temperatures approaching 400° F. Cu over 3 % has an embrittling effect at such temperatures. Attention should be given to the materials for brake drums as increasing car speeds have subjected these parts to temperatures as high as 800° F. The British Aluminum Co. states that an Al alloy containing 1.3 % Cu, 2.2 Si, 1.3 Ni, 1.0 Fe, 0.1 Mg and Ti, known as RR50, has good casting properties, shows high impact fatigue resistance and maintains a fair degree of strength at high temperatures. This alloy is used in many leading aircraft engines in England. Forged pistons in engines of a heat treated aluminum "Y" alloy (similar to alloy H, A.S.T.M., B26-30T) shows favorable characteristics. It is also stated that cast iron pistons wear even longer when no dirt is admitted to the engine. There seems to be no doubt that the life of cast iron pistons is double that of Al pistons. WAT (29)

Impact Characteristics of Steel Rails at Low Temperatures. J. F. Cunningham & J. Gilchrist. *Rolling Mill Journal,* Vol. 5, Nov. 1931, pages 731-732.

Tests are described made to ascertain the behavior of rails at low, sub-zero temperatures at which many fractures occur; tests were made on new and used rails. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 325. Ha (29)

Extreme-Temperature Metals. H. W. Gillett. *A.S.T.M.-A.S.M.E. Joint Research Committee Symposium on the Effect of Temperature on the Properties of Metals,* Feb. 1, 1932, *Preface; Mechanical Engineering,* Vol. 54, Feb. 1932, pages 113-114.

Abridgment of preface to the above symposium published in book form jointly by the American Society for Testing Materials and the American Society of Mechanical Engineers. It is pointed out that the keynote to the whole symposium is found in the opening paragraph of the first paper, where Kerr states that the engineer who now has immediate requirements in advance of what can be supplied will make those requirements still more stringent in the future. Very few of the alloys listed in the 1924 symposium as most promising for high temperature service, have survived in 1931. They have been replaced by better alloys. While Cr and Ni are the vital elements in high temperature alloys considerable attention is directed to the use of W and Mo as well as nitrided steels. Mention of Konel metal which bids fair to show outstanding creep resistance, brings Co also into the picture. Boegehold and Johnson indicate that the automotive engineer would be receptive to Be-Al piston alloys. Much further research is needed to develop high-temperature data on cast iron and on many Al- and Cu-base alloys. Spooner and Foley find sufficiently numerous data on long-time tests so that they discard entirely all quick-pull tests as of too little value to cite. While many papers express an implied or an explicit desire for an accelerated creep test, there is a general feeling that the little knowledge obtained by the various short-cut methods so far developed is a dangerous thing. The warnings of Bailey and of Chevenard that it is still prudent to draw conclusions only from truly long-time tests indicate that careful foreign thought is in agreement with the cautious attitude of most American investigators. Bull indicates that foundry practice governs the high-temperature service of cast alloys as much as the alloy composition. It is pointed out that large crystal size is advantageous, as in a cast structure as compared with a forged structure. Chevenard points out further that increasing doubt is being thrown on the existence of anything that can properly be termed a creep limit. Comparison is now more commonly made on the basis of some defined rate of creep, or of no perceptible creep within a certain precision of measurement. WAT (29)

REDUCTION METALLURGY (31)

Blast-Furnace Reactions. COLIN DUNCOMBE ABELL. *Foundry Trade Journal*, Vol. 45, Dec. 10, 1931, page 362.

A paper presented before the West Yorkshire Branch of the Institute of British Foundrymen. The address dealt with several aspects of the cold-blast-furnace process not usually discussed in text books. OWE (31)

Production of Lead-Tin Alloys from Tin Slags. (Die Herstellung von Bleizinnlegierungen aus Zinnschlacken.) E. R. THEWS. *Die Metallbörse*, Vol. 21, Jan. 3, 1931, pages 3-4.

Twelve different economic and metallurgical factors controlling the success of the melting process are pointed out. The utilization of Sn-bearing Pb ashes, the use of oxidized Pb ores, the influence of As, the adoption of charcoal, the composition of the charge, the alloys obtained and the melting of a Sn-Fe alloy are covered. EF (31)

Limiting Factors in Quicksilver Metallurgy. C. N. SHUETTE. *Engineering & Mining Journal*, Vol. 132, Nov. 9, 1931, pages 398-400.

Progress in the metallurgy of Hg has been directed principally toward reducing the limit imposed by the lowest grade of ore that may be treated profitably. The principle progress has been in the development of furnaces for the treatment of finely divided low-grade ore. The design of the condensers is highly important. Economic figures are presented. WHB (31)

Roasting of Spathic Iron Ore in a Shaft Furnace (Das Rösten von Spateisenstein im Schachtofen mit Aussenfeuerung). E. VOGEL. *Stahl und Eisen*, Vol. 51, Dec. 3, 1931, pages 1504-1505.

In calculating the best economic conditions in roasting spathic ore in a shaft furnace with heating gases and cooling the roasted material by air, it was found that the fuel consumption is lower, the lower the temperature at which the ores are discharged and the more complete is the oxidation of the ores in the shaft. Therefore, it is necessary to use a great excess of combustion air and great volumes of cooling air. GN (31)

Progress in the Reduction and Refining of Copper during 1930. FRED. LAIST. *Mining & Metallurgy*, Vol. 12, Jan. 1931, pages 47-49.

New Cu plants, smelting processes, heat economy and waste heat recovery are considered. Ha (31)

Correlated Data of Blast Furnaces. (Hochofenzahlen und ihre Beziehungen zu einander.) A. WAGNER & A. HOLSCHUH. *Archiv für Eisenhüttenwesen*, Vol. 5, Dec. 1931, pages 279-290.

The report checks the formula which has been developed by E. C. Evans & F. J. Bailey to calculate the consumption of C for melting pig Fe in the blast furnace (*Journal Iron & Steel Institute*, Vol. 117, 1928, pages 53-144; E. C. Evans, L. Reeve & M. A. Vernon, *Journal Iron & Steel Institute*, Vol. 123, 1931, pages 95-181; G. Eichenberg & R. Hahn, *Archiv für Eisenhüttenwesen*, Vol. 3, 1929/30, page 213). It contradicts the assumption of Evans and Bailey that the heat losses through radiation are related to the area of the hearth but shows that the heat efficiency of the blast furnace is greatly affected by the radiation losses/ton of pig Fe. The findings of Evans and Bailey on the influence of the moisture of the combustion air upon the C consumption/ton of pig Fe need further study. The consumption of C was found to be lowest during winter, whereas the content of moisture of the air attains its minimum during the winter. GN (31)

The Thermal Dissociation of Pyrite. (Dissociation Thermique de le Pyrite.) LOUIS D'OR. *Journal de Chimie Physique*, Vol. 28, July 1931, pages 377-408.

Pyrite on thermal dissociation passes through the following systems: a complex gaseous phase, consisting of various kinds of sulphur molecules, S, S_2, S_6 and S_8; a primary solid phase which is the pyrite itself, in hemihedral cubes; a second phase (solid) which is a solution of S in FeS, in holohedral hexagonals. These 3 phases give place to a monovariant equilibrium. The partial pressures of the different kinds of molecules may be calculated by the following formula: $p = T \times 10^{-\frac{A}{T} + B}$

For S_2, A = 13,380 B = 13.8205 (p in mm.Hg)
For S_6, A = 26,464.5 B = 26.4195
For S_8, A = 33,170 B = 32.246
} first approximation

The pressure of the S is negligible as compared with that of the other constituents. The results of a study of the dissociation by means of a spiral quartz manometer, very carefully and accurately installed and controlled are shown diagrammatically. A preliminary series of measurements was made on the hexadiedral crystalline pyrite, a second series on triglyph pyrite. The deduction of equations for partial pressure was based on the hypothesis that the only constituents of S fumes are S, S_2, S_6 and S_8. The work reported indicates that there is still another kind of S molecule which Preuner and Schupp's work did not show and which occurs between the equilibria in the dissociation of the pyrite. But, as in the conditions of that equilibrium, this molecule only seems to play a secondary part; higher values for the coefficients of the pressure equations may be adopted in the primary approximation. As for the equation $P = \Sigma p$, with the coefficients mentioned, it represents faithfully enough (within limits of experimental error), the total pressure measured. The reaction FeS + S fumes $\rightleftarrows FeS_2$ is easily brought about in the 2 directions at temperatures of not less than 500-730° C. Below 500° the recomposition of the pyrite takes place slowly. The mechanism of the reaction is multiple; consideration of the structure of the pyrite shows that it is probable that the S can disengage itself from the pyrite directly to the molecular state S_2, and allow the dissociation to take place simultaneously according to: Pyrite $\rightarrow$ pyrrhotite + S: and Pyrite $\rightarrow$ pyrrhotite + S_2, the former process increasing in importance as the temperature rises. MAB (31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Enamel Containing Antimony for Cooking Utensils. HUGO KUHL. *Glashütte*, Vol. 60, 1930, pages 886-887.

In most enamels, antimony exists in its trivalent state which is most stable. The pentavalent compounds are converted into trivalent compounds by the loss of oxygen during fritting, long firing or high temperatures. 3% solutions of tartaric acid or 4% acetic acid dissolve antimony from enamels in very small quantities. WAT (32)

Testing of Paints for Bending Strength and Adhesion (Zur Prüfung von Anstrichen auf Biegefestigkeit und Haftvermögen). R. KEMPF. *Oberflächentechnik*, Vol. 8, Dec. 1, 1931, page 247.

An apparatus is described in which a thin steel ribbon on which the paint to be tested is put is continually moved in an S-shape between 2 rollers so that the paint is bent first one way, then the other alternatingly. It can be used for other materials, also. Ha (32)

Concrete Coverings Used for Pipe Lines. J. F. HOUGH (Portland Cement Association). *Oil & Gas Journal*, Vol. 30, June 4, 1931, pages T-78-84.

The advantages of a concrete coating for pipe lines are protection against corrosion, elimination of soil stress effect found in bituminous coatings, addition of strength to the pipe, prevention of "floating" of gas pipe out of the trench, creeping of pipe in the trench will not disrupt the cement coating, and quickness of application. VVK (32)

The Technique of Vitreous Enamelling. J. E. HANSEN. (Ferro Enamel Corp.). *Sheet Metal Industries*, Vol. 5, May 1931, pages 23-29; June 1931, pages 97-103; July 1931, pages 179-182; Oct. 1931, pages 423-428; Dec. 1931, pages 557-560.

Handbook concerned with wet process enamelling. The classification of enamels is given, i. e., one-coat agate or granite ware, etc. Selection and fabrication of enamelling materials and the importance of the design of parts to be enamelled are discussed. Part II. The preparation of the pieces for enamelling. The author recommends that mold facings be omitted and discusses pouring practice, cleaning of the work, and cupola practice. Part III. The pickling and cleaning processes. A 6% solution of H_2SO_4 heated to 140°-150° F. is recommended over one of 11% muriatic acid. Part IV. Enamel mill room practice is treated. The author recommends that a sufficient number of mills be installed so as to avoid repeated cleaning for color changes or enamel changes. Need for uniform mill practice is stressed and the ill effects of too small a mill charge are shown in the fifth part. Color matching and the methods of obtaining definite colors in both sheet iron and cast iron enamels constitute the major portion of the article. AWM (32)

Development of Low-Temperature Enamels on a Fluoride Eutectic Basis. JOHN F. HUNT & R. M. KING. *Journal of the American Ceramic Society*, Vol. 15, Feb. 1932, pages 116-121.

Three fluoride eutectics were substituted for cryolite and fluorspar in three standard enamels: sheet-steel ground coat, sheet-steel cover coat, and cast iron single coat, with a view to lowering their maturing temperature. Substitution in ground coats produced inferior enamels, but no apparent change was evident in cast iron enamels. In the case of sheet-steel cover coats satisfactory enamels were obtained with a maturing temperature 150° F. lower than the original enamel which matured at 1450° F. WAT (32)

Viscosity Control of Machine Coatings. F. J. GAVIN. *Metal Cleaning & Finishing*, Vol. 3, Feb. 1931, pages 137-138.

The methods of controlling the viscosity by first accurately determining the rate of solvent loss and then providing means of adding definite and correct portions of thinning materials is discussed. Ha (32)

Primers, Pigments and Paints. (Farbenbindemittel, Farbkörper und Anstrichstoffe.) W. HUSSE. *Zeitschrift Verein Deutscher Ingenieure*, Vol. 75, Oct. 31, 1931, page 1373.

The properties required for rust-proof coatings are discussed and the nitro-cellulose lacquers especially investigated as to their suitability and which methods are best applied for their use. Ha (32)

Paint as a Protective Medium for Iron and Steel. ERNEST S. HEDGES. *Chemical Age*, Vol. 25, Aug. 15, 1931, pages 148-149.

Adherence and functions of the paint film; protective effect of pigment; effect of corrosion products. VVK (32)

Finishing Aluminum Shingles. F. J. GAVIN. *Metal Cleaning & Finishing*, Vol. 3, Jan. 1931, page 55.

The article gives a complete description of the process of applying enamels to the surface of aluminum shingles. Ha (32)

Metals and Mortars. (Metalle und Mörtelstoffe.) D. DIECKMANN. *Tonindustrie Zeitung*, Vol. 55, Oct. 29, 1931, pages 1211-1212.

The rust protection of iron by concrete is critically discussed and the detrimental effect of the "Sorel" cement ($MgO + MgCl_2$ solution) as well as the corrosion acceleration by gypsum are criticized. The reverse behavior towards lead is pointed out. EF (32)

The Use of Turpentine and Volatile Thinners in Finishing Materials. R. W. BRANDT. *Metal Cleaning & Finishing*, Vol. 3, Jan. 1931, pages 59-60.

Production and use of turpentine, benzine, benzol and others is discussed. Ha (32)

Protection of Aviation Materials by Means of Paints, Varnishes and Dopes. (La protection des materiaux en aeronautique au moyen de peintures, vernis, enduits). G. DIXMIER. *Revue de Metallurgie*, Vol. 28, Dec. 1931, pages 690-694.

Good check on adherence and continuity of coating substances can be obtained by making the base metal a pole in the properly devised electric circuit, immersing it in a salt solution, placing the second electrode into the solution and deforming the base metal until the continuity of the protective film is destroyed, closing the circuit. For deformation a Guillery machine (a modification of Erichsen) is quite suitable. Curves obtained with different varnishes on the same base and with the same varnish but on differently finished base are given. JDG (32)

MANUFACTURERS' LITERATURE REVIEWS

364 **Testing Machine**—The Steel City Testing Laboratory, Detroit, Michigan, has prepared a leaflet describing their Universal Hydraulic Testing Machine, Type MP 10. This machine is for tensile, elasticity, compression, bending, folding, shearing, punching and Brinell hardness tests.

365 **Air Tools**—Catalog AT 2000 of the Madison-Kipp Corporation, Madison, Wis., is devoted to their chippers, filers, grinders and accessory parts for these tools. It includes a description of their steel writer which writes on glass or steel almost as quickly as writing with a lead pencil.

366 **Shears**—Bulletin E-902 of the United Engineering & Foundry Co., Pittsburgh, Pa., illustrates and describes their various types of light shears of inexpensive construction for use in the rolling mill.

367 **Grinding**—An interesting article in the March issue of *Grits and Grinds*, published by the Norton Company, Worcester, Mass., is entitled "Grinding Alloy Steel Bar Stock by the Centerless Method."

368 **Furnaces**—Bulletin No. 329 of the W. S. Rockwell Co., 50 Church St., New York, N. Y., discusses their continuous furnaces of the pusher type, both electric and fuel fired. Several pages are devoted to sketches showing designs which have been developed to meet different requirements.

369 **Magnetic Switches**—The General Electric Co., Schenectady, N. Y., has just issued an attractive bulletin, No. GEA-1568, showing their different types of magnetic switches. The construction of these switches is illustrated.

370 **Lead**—The March issue of this publication of the Lead Industries Association, Graybar Building, New York, contains several write-ups on unusual and interesting uses of lead, including lead faced building blocks, lead sidewalk flashing and lead-asbestos anti-vibration pads.

371 **Arc Welding**—An 80-page booklet prepared by The Hobart Brothers Co., Troy, Ohio, is designed to present such facts about the electric arc welding process as are essential to its successful application to practical work. It is a brief, logical and non-technical manual.

372 **Gas Carburizing**—A recent pamphlet put out by the Surface Combustion Corp., Toledo, Ohio, contains a reprint from the April issue of *Metals & Alloys*. It is a description of the continuous gas carburizer, installed at the Chrysler Corporation's plant at Newcastle, Indiana.

373 **Bright Annealing**—A leaflet distributed by the Electric Furnace Co., Salem, Ohio, describes the Preeco special atmosphere electric furnaces for bright annealing in one operation.

374 **Welding Electrodes and Accessories**—Bulletin GEA-1546 of the General Electric Co., Schenectady, N. Y., illustrates the proper applications of their electrodes. A portion of the booklet is given over to a list of their welding supplies and accessories.

375 **Circuit Breaker**—The Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., has issued two 8-page circulars on its new line of "De-ion" circuit breakers. These breakers use a new method of arc extinction that enables elimination of all fuses in panelboards, distribution switchboards within the breaker's capacity and industrial applications where fused safety switches are now used. Circular 1939 contains a general description of the new breakers and Circular 1937 gives construction and application details of the 225-ampere breaker.

376 **Arc Welding Supplies**—A new 24-page bulletin, No. 3304, of the Lincoln Electric Co., Cleveland, Ohio, gives a full description with prices of electrode holders, cables, protective lens, protective clothing and various supply parts as well as electrodes for all kinds of welding.

377 **Testing and Balancing Machines**—Catalog 50-Part H of the Tinius Olsen Testing Machine Co., Philadelphia, Pa., is a 116-page book devoted to their miscellaneous testing machines for efficiency of cutting or abrasion tools, alternate stress in materials, impact, torsion, cold bend, hardness, as well as for oils and bearing metal and other special purposes. The price of this catalog is $1.00.

378 **Thermalloy**—Bulletin 100 of the Electric Alloys Co., Elyria, Ohio, gives the analyses of the various grades of Thermalloy, and a short description of the physical properties of each type. These are heat and corrosion resistant alloys.

379 **Molybdenum in 1931**—This booklet, published by the Climax Molybdenum Co., 295 Madison Ave., New York, N. Y., is divided into three parts. The first is a reprint of an article, "Molybdenum, Today and Tomorrow," which appeared in *Metals & Alloys*, the second is a selected bibliography, and the third describes some of the work of their own laboratory.

380 **Welding**—A feature article in the May issue of *Oxy-Acetylene Tips*, published by the Linde Air Products Co., 30 East 42nd St., New York, is entitled "Controlling Expansion and Contraction." Another interesting article in the same issue is "Inexpensive Automotive Repairs."

381 **Refractories**—A new catalog No. 232 issued by McLeod & Henry Co., Troy, N. Y., describes various types of super-refractory blocks and bricks, as well as complete settings made of silicon carbide. The catalog includes, in detail, the manufacturing processes for silicon carbide refractories, their physical characteristics, advantages, limitations and a description of applications for industrial furnaces, kilns, muffles, etc.

382 **Electric Immersion Heating Units**—Bulletin No. 270 of H. O. Swoboda, Inc., Pittsburgh, Pa., describes their bare electric immersion heating units for asphalt, pitch, oil, varnish and similar viscous substances with electric insulating qualities.

383 **Roll Polisher**—A folder issued by the Aetna-Standard Engineering Co., Youngstown, Ohio, contains several photographs which demonstrate the mechanical features of their equipment for polishing sheet and tinplate rolls.

384 **Nickel Comparator**—The Kocour Co., 4724 S. Turner Ave., Chicago, Ill., has issued several leaflets and booklets describing their apparatus for the determination of the nickel content of electroplating and electrotyping solutions. They also supply a test set for determining the relative strength of alkaline cleaner solutions.

385 **Abrasives**—A booklet published by The Carborundum Co., Niagara Falls, N. Y., entitled "Abrasive in the Service of Industry" gives a short historical sketch of the art of shaping and finishing metals by grinding, including a discussion of present day practice and ending with a short chapter on the possibilities of the future.

386 **Die Steel**—The Research Department of Ludlum Steel Co., Watervliet, N. Y., has issued a "Blue Sheet" which contains brief but detailed information concerning the physical properties and characteristics of Ontario air hardening die steel. It includes tabulated and charted results of tests conducted on the steel.

387 **Protective Coating**—The Quigley Co., Inc., New York, N. Y., has prepared a booklet discussing their Triple-A Protective Coating, and giving a list of many industries now using this coating to meet their corrosion problems.

388 **Copper & Brass Bulletin**—The April issue of this publication of the Copper & Brass Research Association, 25 Broadway, New York, describes many things made from copper and brass, from the copper roof of a Chinese temple to items made of copper and brass available in the 5 and 10 cent stores.

389 **Metallurgical Microscope**—Clay-Adams Co., Inc., New York, N. Y., has issued several mimeographed sheets giving complete specifications for their metallurgical projector, microscopic and micro-photographic apparatus which they call "Opacus." Illustrations of the apparatus are shown and prices for it and its accessories are given.

390 **Foundry Practice**—The feature article of the April issue of *Better Methods*, published by The Beardsley & Piper Co., Chicago, Ill., is entitled "Producing Castings for Dry Process Enameling." The several other articles in this issue will also be of interest to foundrymen.

391 **Testing Machines**—Bulletin No. 28 of the Baldwin-Southwark Corp., Philadelphia, Pa., is a 36-page pamphlet which gives a short historical sketch and development of the machines and full description with illustrations and diagrams of their 20,000-100,000 lb. testing machines, the 200,000-600,000 lb. machines and those for 600,000 lb. and up.

GENERAL (0)

Sheet Steel and Tin Plate. R. W. SHANNON. Chemical Catalog Co., New York, 1930. Cloth, 6¼ x 9¼ inches, 285 pages. Price $5.00.

Shannon's book is the only one of its kind that has come to our attention. There are many well-known publications relating to the metallurgy and heat treatment of steel, the processes involved in shaping and preparing it for subsequent use, and the methods of applying protective coatings to various steel products, but this treatise fits comfortably into a niche that has not been filled heretofore. Any one who reads the book in the interest of learning more about sheet steel and tin plate will not be disappointed. The subject matter has been well chosen and is treated to good advantage throughout the volume.

It is particularly fortunate that the author decided to handle his subject primarily for the guidance and benefit of the consumer. With the extensive diversity of products and grades now produced to meet the requirements of the trade, a descriptive guide of this kind is unquestionably valuable. For all those who use or contemplate the use of sheet steel and tin plate in any way—for engineers, architects, purchasing agents, writers of specifications, sheet metal workers, dealers, salesmen, and students of the subject—here is a fund of information that will be usually helpful.

The reviewer's emphasis on the foregoing feature is not intended to divert attention from the other useful elements in the book. The foundation for the special treatment of the subject has been well laid by a discussion of each successive and essential step in the process of production. The reader can obtain, from the earlier chapters, a very good understanding of the various methods employed in the industry and the bearing they have upon the properties of the finished products.

The few technical inaccuracies encountered in this work are relatively unimportant from the standpoint of the consumer and do not detract from the general value of the publication. Incidentally, even those who are well informed on the subject will find the descriptive matter and various compilations of data convenient for ready reference.
R. E. Zimmerman (0)-B-

Metallurgie. Agenda Dunod 1932. R. CAZAUD. Dunod, Paris, 1932. Cloth, 4½ x 6 inches, 371 pages. Price 20 Fr.

The 48th edition of one of a series of handbooks on various phases of technology, engineering, industry, and commerce, this volume is intended to serve managers, engineers, superintendents, foremen, etc.

Admittedly, limitation to less than 400 very small pages renders most difficult the description, even briefly, of the raw materials, equipment, and processes for the preparation of the common and semi-rare metals, their statistics and the properties and uses of them and their alloys. As a result, some subjects have received proportionately too detailed treatment and others insufficient. For example, there are drawings of almost every type of electric melting and refining furnace and of an electric iron reduction furnace, but none of a blast furnace or open hearth or Bessemer converter. Tables show the dimensions of standard structural shapes but there is not treatment of hot and cold working. The sketchy character and sense of incompleteness thus resulting in parts of the book could have been completely avoided by slight rearrangement and perhaps 50 additional pages of text.

On the other hand, principles of each subject discussed are very clearly presented and classification of materials and processes used to introduce many of them. The treatment of metals other than iron seems in most cases better balanced.

Subjects considered are metallurgical agents (fuels, refractories, slags), apparatus (furnaces, blowers, etc.), thermal control (pyrometry and gas analysis), metallurgy of iron (cast iron, wrought iron, steel), electrometallurgy (reduction, refining, melting), mechanical testing, physical metallurgy (equilibria, micrography, macrography, heat treatment), and metals other than iron (preparation, alloys and uses of Cu, Pb, Zn, Cd, Sn, Ni, Co, Sb, Hg, Al, Mg, Bi, Be, Au, Ag, Pt, Cr, Mo, Mn, W, V, Ti, Zr. Jerome Strauss (0)-B-

English Terms Used for Gears. (Englische Bezeichnungen für Zahnräder.) FRITZ G. ALTMANN. *Maschinenbau*, Vol. 10, May 21, 1931, pages 351-354.

Some 200 German terms and their English equivalents, arranged in 2 sections, German to English and English to German, the former by subject, the latter alphabetically, are given.
MAB (0)

Chemical Composition, Shaping and Heat Treatment of Steel. (Chemische Zusammensetzung, Formgebung und Wärmbehandlung des Stahles.) H. BENNEK. *Die Wärme*, Vol. 54, Apr. 25, 1931, pages 300-304, Sonderheft "Werkstoff und Herstellung im neuzeitlichen Dampfkesselbau."

Structural changes and changes in physical properties due to the addition of the most important alloying elements. Relationship between rate of deformation and strength values. Recrystallization, aging and etching for stress flow lines. Purpose of heat treatment and possibilities of defects. Hardening through in relation to cross section and amount of alloying elements present. The paper which deals with the problems outlined above was presented before the Zentral Verband der Preussischen Dampfkessel Ueberwachungsvereine, 1931.
EF (0)

Practical Research Results on Non-Ferrous Metals. *American Metal Market*, Vol. 38, Aug. 1, 1931, pages 3, 10.

Reprinted from "Ten Years of Research for the Metal Industries," by British Non-Ferrous Metals Research Association. Researches are on atmospheric corrosion and tarnishing of metals and study of effect of impurities on Cu. Progress made in ternary Pb alloys for cable sheathing, water pipe, Al brass condenser tube, Sn solders, locomotive fire box and stay copper, brass castings, alloys for high temperature service, autogenous welding of Cu, annealing furnace practice, spectroscopic assay of metals, electro-deposition, gases in metals, galvanizing, die-casting alloys, condenser tube corrosion, Ni researches, Zn sheet, Al, Sn, etc.
DTR (0)

The Book of Metals. DONALD WILHELM. Harper & Brothers, New York, 1932. Cloth, 6¼ x 9½ inches, 341 pages. Price $4.00.

Some 35 eminent metallurgists have given the author correct technical facts in regard to iron, steel, alloy steels, aluminum, copper, brass, bronze, nickel, zinc, lead, tin, gold, silver and the platinum metals, and he has strung them together and rephrased them with the idea of making the facts understandable, in particular to two boys of 14 and 16, to whom the book is dedicated, and to others of the same mental age, as far as previous knowledge of metallurgy goes. The volume is said by the "Scientific Book of the Month Club" to be "breezy, non-technical and accurate."

We tried to get a 15-year old boy to read it, but couldn't persuade him to get more than half-way through it. Perhaps that was the fault of the boy and not of the book, or due to competition from various detective stories the boy was then reading of his own accord.

To the reviewer's mind, the somewhat flippant, "breezy" style in which Wilhelm tries to make the book a popular one by his own interpolations, adds nothing to the interest of the book, even to a youngster. Most youngsters dislike being "written down to," and the parts that are quoted more or less verbatim from writers like Jeffries, Frary, Welty, Stanley, Agassiz and Griffiths, which are clearly put but not written in advertising parlance, will probably appeal, both to young and old readers, more than Wilhelm's own part.

Due to the guidance of the metallurgists who have helped the author, the material is accurate in general. Reference to a "slope" instead of a stope in a discussion of mining, to an automobile "toppet" valve, and to the dimensions of Solomon's brass bowl "9 feet high and nearly 18 inches from brim to brim," are the only actual errors noted.

The few photographs by Margaret Bourke White are, of course, superb. These and the occasional relief from Wilhelm's style afforded by the quotations from others are the most attractive features of the book.

The material in the volume is good. We don't personally care for the type of sugar-coating used, but if any non-technical readers do want to know something about metals, this is an accurate book for them to read.

Second and Third Supplements to the Non-Ferrous Metals Handbook. (Nachtrag II und Nachtrag III zum Werkstoffhandbuch Nichteisenmetalle.) Beuth Verlag, Berlin, 1931. Loose leaves, 5¾ x 8¼ inches, II, 28 pages, III, 28 pages. Price 3.15 RM each.

These additions to the German non-ferrous metals handbook cover compression testing, creep and fatigue testing, electroanalysis, potentiometric analysis, microscopy and macroscopy, lead, torsion testing, corrosion test methods, working of Al, electric melting furnaces, metallic coatings. They are quite brief, but cover the high spots and generally give a selected bibliography that will lead to more detailed information. The page on creep testing is not helpful. Most of the others are as accurate as can be expected with such brief treatment.

Profitable Practice in Industrial Research. Edited by M. Ross. Harper & Brothers, New York, 1932. Cloth, 5¾ x 8¾ inches, 269 pages. Price $4.00.

Fourteen articles by directors of research are assembled into this book, which is published under the auspices of the National Research Council. Jewett and Mills of the Bell Laboratories, Kettering of General Motors, Whitney and Hawkins of General Electric, Mees of Kodak, Skinner of Westinghouse, Stine of duPont, Burgess of Standards, Weidlein of Mellon, Jackson of Massachusetts Institute of Technology, together with Sparagen, Holland and Little, discuss research from their own points of view.

These articles give a good picture of the usefulness of research and the general principles of operation of research laboratories in individual firms, government bureaus, universities, consulting laboratories and trade associations. The research programs of technical societies, such as the American Society for Testing Materials, might well have been given a chapter.

The book is useful to the research worker, but still more useful to the executive interested in the possibilities and limitations of research in adding to the profits of his firm. Research is a specialized business, requiring a certain type of worker, a certain environment, and a certain permanent position in the affairs of the firm utilizing it, if it is to pay dividends. The experience of experts who have made it pay is available in this volume.

Limitations of our Fundamental Knowledge of the Properties of Metals. F. O. CLEMENTS. *Lecture at joint meeting American Society for Testing Materials and American Institute of Mining & Metallurgical Engineers*, Feb. 18, 1932. Advance copy, 7 pages. Mimeographed.

Popular-type discussion, sometimes jocular. Lists atomic structure, mechanism of hardening steel by quenching, reasons for variability in heat-treating of heats of similar chemical analysis, distortion on heat-treatment, catalytic action of metals, metals of high elastic modulus, high temperature properties, endurance of notched steels and of carburized steels, damping, wear, machineability, magnetic properties, etc., as subjects on which relatively little progress has been made compared to what is needed. Failure of the Ambassador bridge cables is cited as puzzling. Automobile engineers desire to build lighter vehicles; hence corrosion-resistant light alloys are needed.

Photoelectric Properties of Zinc Single Crystals. J. H. DILLON. *Physical Review*, Vol. 38, 1931, pages 408-415.

An experiment is described in which the photoelectric properties of outgassed single crystals of Zn were studied. After the emitting surfaces of the crystal had been treated with ultraviolet light and some of the Zn evaporated thermally, a stable condition was reached. In this stable condition a difference in the long wave limits of the polycrystalline surface and cleft 0001 face of approximately 260 A.U. was observed. The results are discussed with regard to possible sources of contamination and the presence of occluded gas layers. WAT (1)

The Electrical Conductivity of Single Aluminium Crystals in Directions Inclined at Various Angles to the Crystal Axes. MALCOLM FRASER. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, July 1931, pages 112-129.

Single Al crystals were prepared by the method of Carpenter and Elam, consisting (briefly) of 2 heatings and one stretching. The purity was from 99.6 to 99.75%. The orientation of the crystal axes of the face-centered cubic system into which Al crystallizes were determined by the Laue spot method. Within the accuracy of the experimental methods (1%) the specific electrical resistance was found to be independent of the orientation relative to the crystal axes. It was about 1% greater than that of the annealed material from which it was prepared; this is ascribed to the solution of impurities in the long annealing process for preparing the single crystal. 10 references. Photoelectric and Thermionic Properties of Palladium. LEE A. DUBRIDGE & W. W. ROEHR. *Physical Review*, Vol. 39, Jan. 1, 1932, pages 99-118.

The photoelectric and thermionic properties of pure palladium have been studied during an extended outgassing in high vacuum. The threshold, obtained by extrapolation of special sensitivity curves, shifted from below 2300 A.U. to above 3000 A.U. and then back to a final value of 2486 A.U. as outgassing progressed. In the final state the photocurrents excited by monochromatic light increased with temperature; the relative increase was greater for the longer wavelengths. At the higher temperatures (1100° K.) the spectral sensitivity curves approached the axis asymptotically. The results are shown to be in excellent agreement with Fowler's recent theory and his methods of analysis yields the value 4.97 ± 0.01 volts for the true work function (2486 A.U.). The thermionic work function for the clean specimen was found to be 4.99 ± 0.04 volts, and the value of the constant A is very close to 60 amp./cm.^{2}deg.^{2}. WAT (1)

Physical and Chemical Properties of Rhenium. (Physikalische und Chemische Eigenschaften des Rheniums.) C. AGTE, H. ALTERTHUM, K. BECKER, G. HEYNE & K. MOERS. *Zeitschrift anorganische und allgemeine Chemie*, Vol. 196, Feb. 23, 1931, pages 129-159.

A comprehensive review of the properties of the new metal rhenium is given of which the most important points are: the metallic properties are similar to W (high melting point) and to Os (semi-rare metal, high ductility). Melting point 3440° ± 60° absolute. Specific electrical resistance 0.21 x 10^{-4} ohm. cm. = 15% (4 times greater than W); temperature coefficient between 0° and 100° = 3.11 x 10^{-3}. The electron emission between 1900° and 2700° absolute is only about ⅛ to ¼ that of W. It can be hot forged, rolled and hammered; tensile strength about 50 kg./mm.^{2} with 24% elongation. Heat expansion coefficient in the c-axis is 2.6 times greater than in an axis vertical to it; in β (001) = 12.45 x 10^{-6} ± 8%, and in β (100) = 4.67 x 10^{-6} ± 8%. Rhenium can be obtained by electrolysis in only very limited amounts as a cathodic coating. It is considerably more resistant to oxidizing gases than W. The presence of Re can be proven analytically by precipitating mercury-and thallium-perrhenate, or with brucine and veratrine. The line spectrum of Re is given and its presence can be detected by this means as well. The heat quantitative method is in the form of NH_4ReO_4. Rhenium metal is easily dissolved in HNO_3, slowly in H_2SO_4, and to a limited extent in HF and HCl. Carbides, nitrides and amalgams could not be formed. Ha (1)

Some Relation Among the Ferromagnetic Constants. J. R. ASHWORTH. *Proceedings Physical Society*, London, Vol. 42, Aug. 15, 1930, pages 449-452.

Attention is directed to a ferromagnetic equation written after the model of van der Waal's equation of state for fluids. It is shown that the ratios of the absolute critical temperatures to the maximum intensities of magnetization are nearly the consecutive numbers 2, 3, 4, 5, 6 for Fe, Co, Ni, Heusler's alloy and magnetite, respectively. A formula for the discontinuity of the specific heat at the critical temperature is derived which agrees well with experimental determinations and a simple formula is given connecting this discontinuity with the true specific heat at the critical temperature. Certain simple relations among the constants of ferromagnetism disclose themselves which show that the ferromagnetic properties of Fe and Ni are to one another as those of Co and magnetite. See also *Metals & Alloys*, Vol. 2, Sept. 1931, page 159. (1)

Rhenium (Rhenium). C. AGTE & K. BECKER. *Die Umschau*, Vol. 35, June 27, 1931, pages 520-522.

Some Photoelectric Properties of Mercury Films. DUANE ROLLER, W. H. JORDAN & C. S. WOODWARD. *Physical Review*, Vol. 38, Aug. 1931, pages 396-407.

Films of very pure Hg were deposited slowly in a high vacuum on an oxidized Fe plate maintained at liquid air temperature. As each film increased in thickness, the photoelectric current excited by each of the Hg arc lines 2537A.U., 2653A.U. and 2700A.U. increased from zero to a maximum value and then decreased to a final constant value. In each the threshold wave-length at the time of maximum sensitivity was about 2750A.U. Its final value, that for a thick layer of mercury, was 2730A.U. ± 15A.U.; this did not change even when the Hg was allowed to melt, this confirming a former conclusion that the threshold wave-lengths for solid and liquid Hg are the same. There was no indication of a large shift in the threshold wave-length at any time during the formation of the films. WAT (1)

The Formation Heat of TiO_2 (Die Bildungswärme von Titandioxyd). W. A. ROTH & G. BECKER (Technische Hochschule Braunschweig). *Zeitschrift für physikalische Chemie*, Bodenstein Festband, 1931, pages 55-60.

Ti was burnt in the calorimetric bomb and the heat of formation determined amounted to +218.7 (±0.3) kg./cal. at a constant pressure. The formation heats of the dioxides of the IV group in the periodic system distinctly show a relationship to the number of order. EF (1)

Investigation of Aluminum Tubes. I. G. SHOULGIN. *U. S. S. R. Science Research Dept. Supreme Council National Economy* No. 448, 1931; *Transactions Central Aero-Hydrodynamic Institute*, No. 80, 1931, pages 1-16.

This investigation was carried out, by the section for testing aeronautical materials, for the purpose of elaborating a system of technical standards of Al tubes. The chemical composition and mechanical properties were determined. The tubes were grouped in 3 classes, according to chemical composition: (1) containing less than 1%; (2) 1-1.5%; (3) more than 1.5% of impurities. As regards the mechanical properties, it is concluded that these are influenced by external defects, and the system of testing employed must depend on the nature of the work performed by the tubes. Normalized tubes up to 20 mm. in diameter should be tested for tension in complete (that is, uncut) sections. Tubes of 20-30 mm. diameter may be tested both in complete and in flat sections. Tempered tubes up to 30 mm. in diameter must be tested uncut. The elongation under tension should be measured along a length of 10 diameters. Tests for elongation and cone-widening of the aperture are regarded as the most characteristic, although compression tests may also be employed. Crushing and bending tests are considered to be useless, as they give no indications of films, pinholes and other flaws. (1)

On an Electromotive Force Between Two Metals in Relative Motion. J. B. SETH, BHISHAMJI GULATI & SWARAN SING. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, Aug. 1931, pages 409-429.

The phenomenon that when 2 metals are rubbed together the seat of rubbing becomes a source of an electromotive force was thoroughly investigated. This is ascribed partly to the rise of temperature, the 2 metals forming a thermocouple and, partly, to the contact of the metals. In the tests, a rotating disk was used and the other metals pressed against it. 2 laws could be established: (1) the e.m.f. is proportional to the relative speed of the 2 rubbing surfaces; (2) the e.m.f. is independent of the pressure with which the 2 surfaces are pressed against each other. The tests are described and discussed in detail. 18 references. Ha (1)

The Behavior of Powdered Metals under Pressure. (Das Verhalten pulverförmiger Metalle unter Druck.) F. SKAUPY & O. KANTOROWICZ. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.-Sept. 1931, pages 482-485.

Electrical conductivity was used as a means of elucidating the behavior of metallic powders in compressing and in sintering at high temperatures. See "Electrical Conductivity of Pulverized Metals under Pressure," *Metals & Alloys*, Vol. 2, May 1931, page 94. Ha (1)

Advances in the Production and Utilization of Some Rare Elements. (Fortschritte in der Darstellung und Anwendung einiger seltener Elemente.) W. NODDACK. *Die Metallbörse*, Vol. 21, Apr. 1, 1931, pages 603-604; Apr. 8, 1931, pages 651-652.

The following elements are treated more or less exhaustively in regard to history, occurrence, production, properties and present commercial importance: He, Ne, Ar, Kr, Xe, Li, Be, Ra, Ce, Ge, Hf, W, F, Rh and the platinum group. EF (1)

The Electron Theory of the Metals, I. and II. (Zur Elektronentheorie der Metalle.) L. NORDHEIM. *Annalen der Physik*, Series 5, Vol. 9, 1931, No. 5, pages 607-640; No. 6, pages 641-678.

The problem of the nature of metals is treated strictly theoretically on the basis of the Fermi-statistics in connection with the theories of Pauli and Sommerfeld. The physical prerequisities for the treatment of the electric and thermal conductivity on the basis of the length of the free path of electrons are explained and the fundamental equations for the thermo-electrical phenomena derived. The solution of this equation and the transition probabilities are discussed, and the results of the investigations can be summed up briefly as follows: Free electrons give a good approximation for the actual conditions of good conductors; Sommerfelds formulas are corroborated for high temperatures, and the free length of path for the electrons gives a useful means for explanation of the dependence of the electric conductivity on the temperature. The behavior of alloys can be satisfactorily explained by the new theory. The application of the theory is demonstrated by the example of an ideal crystal and by the comparison of calculated and observed conductivities of metals and some alloys. Ha (1)

Crystalline Boron (Sur le bore cristallisé). L. Hackspill, A. Stieber & R. Hocart. *Comptes Rendus,* Vol. 193, Nov. 3, 1931, pages 776-778.

The authors have prepared samples of boron containing at least 99% of boron, the material approximating arsenic in color, having a Moh's hardness of 9 and a density at 20° C. of 3.33 ± 0.01. A description is given of experiments they have carried out on the spectroscopic analysis (Debye-Scherrer) of this material. 2 diagrams. OWE (1)

Damping Capacity of Materials. G. S. von Heydekampf. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 157-175.

See abstract of preprint, *Metals & Alloys,* Vol. 2, Nov. 1931, page 256. Includes discussion in which de Forest points out that damping may give information on amount and distribution of non-metallic inclusions. Wrought iron has high damping capacity. Sturm points out that, in creep tests, an alloy of low rate of creep shows high initial set while one of higher creep rate shows lower initial set. This is illustrated by curves of Al-Mn and Al-Si alloys. Creep and damping capacity may be interconnected. HWG (1)

The Photoelectric Effect from Thin Films of Alkali Metal on Silver. Herbert E. Ives & H. B. Briggs. *Physical Review,* Vol. 38, Oct. 1931, pages 1477-1489.

The thin films of alkali metals which spontaneously deposit in vacuo on other metals have long been known to exhibit photoelectric effects which vary in amount and character, depending on the underlying material, but the exact nature of this dependence has been obscure. Ag, because of its region of exceedingly low reflecting power in the ultraviolet and the accompanying variation of optical constants, is exceptionally well suited for studying the influence of the underlying metal. It is found that the region of low reflecting power profoundly affects the photomission, but in a manner not to be explained simply by reduction of light reflected back through the alkali metal film or by the absorption of light by the Ag. The results are very satisfactorily explained upon computing, from the optical constants, the intensity at the surface, of the interference pattern formed by reflection just above the Ag surface. The positions of the maxima and minima of photomission, and their variations with angle of illumination and plane of polarization are accurately indicated. WAT (1)

The Theory of the Magnetization Curve of Isotropic Ferromagnetic Bodies in Medium and Strong Fields (Zur Theorie der Magnetisierungskurve isotroper Ferromagnetica in mittleren und starken Feldern). R. Gans. *Physikalische Zeitschrift,* Vol. 33, Jan. 1, 1932, pages 15-17.

Heisenberg, *Zeitschrift für Physik,* Vol. 69, 1931, page 287, developed a theory which permits the calculation of the magnetostriction of ferromagnetic single crystals and Akulow, *Zeitschrift für Physik,* Vol. 69, 1931, page 794, has used this theory to determine the magnetization curves of single crystals of iron. In connection with this theory, its application for the magnetization of ferromagnetic isotropic metals is discussed with special reference to cobalt. GN (1)

Stannite of Calcium, Strontium and Barium. (Stannite des Calziums, Strontiums und Bariums.) Setsuro Tamaru & Haruo Sakurai. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 195, Jan 7, 1931, pages 24-34.

The conditions under which Sn compounds can be obtained were investigated. With Ca, stannous Ca ($CaSnO_2$), Ca metastannate ($CaSnO_3$) and $CaSnO_4$ were formed. With the other elements $BaSnO_2$ and $SrSnO_2$ could be obtained in a similar manner; the process is described. Ha (1)

Electrolytic Investigations on Single Crystals of Zinc (Elektrolytische Untersuchungen an Zinkeinkristallen). K. H. Kreuchen. (University of Kiel). *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 155, July 1931, pages 161-198.

The electrolytic behavior of an ideal crystal according to Kossel's theory of crystal growth is discussed in the introduction. Single crystals of Zn were prepared by the Bridgeman method. The (0001) cleavage plane in the freshly split state yielded a P.D. of 30 millivolts against the poly-crystal. The author presents his conception of surface potential, specific potential and equilibrium potential and succeeds in obtaining large single crystals of Zn by electrolytic orientated growth. Galvanic cells in which the Zn electrode was substituted by a single crystal yielded queer time/current curves, the course of which are interpreted by the author. EF (1)

Magnesium (Le magnesium). A. Dumas. *Journal du Four Electrique,* Vol. 40, Sept. 1931, pages 354-359; Dec. 1931, pages 474-476.

From 3 major methods proposed for production of Mg (electrolysis of chlorides, reduction at very high temperatures with carbon and electrolysis of magnesia) only the first is widely used. Since it is simple itself, the process depends for effectiveness on the methods for production of chlorides either in the monohydrated or anhydrous form. The former can be used as such or further dehydrated by using KCl. Recently, dry methods of chlorination of the oxides were introduced in which a mixture of globerite and coal is penetrated by the current of chlorine while heated to a high temperature. The Cl and $MgCl_2$ are evacuated. The Cl follows a closed cycle. $MgCl_2$ is electrolyzed in large tanks usually having a refractory lining and an independent set of electrodes. The second part gives the properties of Mg and some of its applications. JDG (1)

The Thermal Expansion and Atomic Heat of Solid Mercury. L. G. Carpenter & F. H. Oakey. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Aug. 1931, pages 511-522.

The investigation was made from — 73° C. to the melting point of Hg, i. e., — 39° C. The test arrangement is described in detail and the results of the cubic expansion coefficient and atomic heat are represented in curves. Ha (1)

Preparation of Pure Magnesium by Sublimation. (Préparation du magnésium pur par sublimation). J. Hérenguel & G. Chaudron. *Comptes Rendus,* Vol. 193, Nov. 3, 1931, pages 771-773.

The authors, requiring pure Mg for experiments designed to determine the corrodibility of this metal, prepared a series of samples of resublimated Mg in apparatus described in the article. Using this apparatus, the Mg contained only traces of chlorine. OWE (1)

Aluminum (Das Aluminium). E. Kuhn. *Dinglers Polytechnisches Journal,* Vol. 345, Mar. 1930, pages 41-43.

Metallurgy of Al; references and table compiling data on physical properties. EF (1)

Influence of the Elastic Stress State on the Magnitude of the Initial Permeability. (Über den Einfluss des elastischen Spannungszustandes auf die Grösse der Anfangspermeabilität.) M. Kersten. *Zeitschrift für technische Physik,* Vol. 12, Dec. 1931, pages 665-669.

The present paper directs attention to the correlation of the initial permeability of ferro-magnetic material to the thermal and mechanical pretreatment: the initial permeability can be increased by proper heat treatment and is cut down by mechanical stress such as rolling and drawing. With reference to Becker's interpretation of the technical magnetization curve, the initial permeability of a ferromagnetic body with large internal stresses is approximately computed. The theoretical derivations are checked by Ni wire which was elastically and plastically drawn. A theoretical relationship permitting the anticipation of the maximum value of initial permeability is satisfactorily confirmed by experiments on several Fe-Ni alloys. EF (1)

Optical Excitation Functions of Cadmium and Zinc Lines. (Die optischen Anregungsfunktionen der Kadmium- und Zinklinien.) K. Larché. *Physikalische Zeitschrift,* Vol. 32, Feb. 15, 1931, pages 180-181.

A paper before the Deutsche Physikalische Gesellschaft, Dresden, 1931, is summarized which refers to (a) the determination of the excitation function of 74 lines of Cd and Zn, and (b) measurements of the relative intensities of Cd and Zn lines and (c) the correlation of the slope of the intensity maxima to the life times of the lines investigated. The Beryllium Molecule. W. H. Furry & J. H. Bartlett. *Physical Review,* Vol. 38, Jan. 1932, pages 210-225.

The interaction of a normal Be atom with one which has an electronic configuration 2s2p has been studied by means of the Heitler-London method. Of the eight possible molecular states, two are calculated to be stable. An attempt to obtain agreement with experiment in the case where a normal Li atom interacts with one in the $2p^2P$ state has not been successful. WAT (1)

Scattering of Hard Gamma Rays. L. H. Gray. *Proceedings Royal Society* (London), Vol. A 130, 1931, pages 524-541.

The relative scattering powers of Mg, Al, Cu, Zn, Cd, Sn and Pb for Ra C γ rays filtered through 4 cm. of Pb, and for Th C γ rays filtered through 3 cm. of Pb have been investigated by observing the ionization produced by radiation scattered within the angular range 10-30°. For Ra C γ rays the decrease of scattering power per extranuclear electron from Mg to Pb is 2%; for Th C γ rays there is a gradual increase of about the same amount, but this is of the order of magnitude of error in the application of the correction for reabsorption of scattered radiation in the scatterer. Therefore these measurements establish the fact that the binding forces in heavy elements do not influence appreciably the scattering power of extranuclear electrons for radiations of energy corresponding to 2×10^6 electron volts. WAT (1)

Photo-electric Effect and Electron Reflection on Hydrogenated Surfaces of Potassium. (Ueber lichtelektrische Wirkung und Elektronenbeugung an hydrierten Kaliumoberflächen.) W. Kluge & E. Rupp (Res. Inst. of Allgemeine Elektrizitäts Gesellschaft). *Physikalische Zeitschrift,* Vol. 32, Feb. 15, 1931, pages 163-172.

A testing method is described which is fitted for carrying out photo-electric measurements and investigations of interferences by means of reflected electrons on the same surface of the metallic sample. The electron reflection maximum led to a value 7.3 V for the inner potential of K and 5.4 A.U. for the lattice constant of KH. EF (1)

The Relative Permeability of Iron, Nickel, and Permalloy in High Frequency Electro-Magnetic Fields. Edwin Michael Guyer. *Journal of the Franklin Institute,* Vol. 213, Jan. 1932, pages 75-88.

Relative magnetic permeability of Fe, Ni, and permalloy measured over range of 70 to 200 meter wave-lengths by heterodyne balance and reasonance methods. Results showed that, when certain definite precautions were observed in making the measurements, nothing suggestive of anomalous dispersion of magnetic permeability in this wave-length region was found. When these precautions were neglected irregular breaks resulted in permeability curves as a function of wave-length which varied in position with conditions of the circuit. High frequency resistance of Fe, Ni, and permalloy wires was also measured over range of approximately 50,000 kilocycles from 2 to 3 meter wave-lengths. As before, when definite precautions were taken in measurements, no anomalous variations at certain frequencies were found to exist. Apparatus of various methods in full, together with graph of results. DTR (1)

Tantalum, the Long Elusive Metal. *Metal Progress,* Vol. 18, Dec. 1930, pages 50-53.

The history and properties of Ta, occurrence of its ore, methods of reduction, and uses of the metal are described. WLC (1)

On the Molecular Spectra of Mercury, Zinc, Cadmium, Magnesium and Thallium. H. Hamada. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, July 1931, pages 50-67.

Results of tests to determine the energy states and spectral excitation of diatomic molecules. It can be stated that a band system emitted from such molecules has 2 broad maxima and one flat minimum of intensity. One of the maxima always coincides with a resonance line; the other lies at the region of longer wave length and is generally connected with a coarse structure. Ha (1)

Recently Discovered Complexities in the Properties of Simple Substances. P. W. Bridgman (Harvard University). *Transactions American Institute Mining and Metallurgical Engineers,* General Volume 1931, pages 17-37.

Science lecture before A. I. M. E. meeting at Boston in Sept. 1931. Due to the extensive study of the atom, physicists have recently been inclined to neglect the study of matter in bulk. Surprisingly complex phenomena recently observed include (1) the so-called structure sensitive phenomena; (2) complexities of such a nature that they are masked by the presence of extraordinarily small amount of impurities; (3) complexities depending on internal molecular rearrangements which can be understood only from the view of the quantum theory. The faults, imperfections or cavities produced at regular intervals in a crystal lattice are discussed under (1). These faults divide the crystal into blocks of from 10^4 to 10^6 atoms each, and account for the low strength shown by matter. Work of Goetz on Bi crystals and Smekal on NaCl is discussed in some detail. Under (2) and (3), complexities observed chiefly at low temperatures or high pressures are treated. JLG (1)

Zinc and Its Alloys. *Bureau of Standards Circular* No. 395, 1931, 214 pages.

The physical and mechanical properties of Zn summarized from the technical literature, together with results obtained at the Bureau, are given. Special consideration has been paid to the effect of structural conditions of the metal resulting from impurities and from such factors as mechanical working, recrystallization, etc., upon the measured physical properties. The corrosion resistance of Zn, especially as related to its usefulness as a protective coating for steel, is discussed. The various alloy systems are summarized from the standpoint of constitution. Particular attention is given to the die-casting alloys and the properties which determine their usefulness industrially. A rather complete bibliography is included in the form of selected references appended to the various sections in which the different properties are discussed. The early history of Zn dating back to the year 500 B. C., is discussed. Many tables, charts, and diagrams illustrate the data presented. It is probably one of the most complete collections of data ever compiled on Zn and its alloys. WAT (1)

Rare Metals—1931 edition. Fansteel Products Co., N. Chicago, Illinois. 70 pages.

This interesting 70 page brochure differs from the 1929 edition in several points. Commercial Ta is now 99.9% pure instead of 99.8%, and costs 1/7 as much as Au instead of ¼. The temperature up to which Ta is not affected by O is revised downward to 400° C. Ta weights for laboratory balances are now available from supply houses. New products described are TaW metal, an alloy of Ta and W, tantalum carbide (Ramet) tools, wire drawing dies, and lapping powder, and metallic Cs and Rb. Smaller sizes of W, Mo and Ta wires are now available and the tables of wire data have been correspondingly augmented. It is stated that powdered Mo is being used in bronze to add resistance to abrasion and impact. The statement that a trace of Mo in iron retards the tendency to rust is also made and may be questioned, since the corrosion-resistant properties claimed for the product in question are supposed to be conferred by Cu; the Mo is added for other purposes. Straight Mo iron is not ordinarily reputed to be improved as to corrosion. On the whole, however, the information in the pamphlet appears essentially reliable, and it shows interesting advances in the production and use of rare metals. HWG (1)

Hydrogenized Iron. P. P. Cioffi. *Physical Review,* Vol. 38, Jan. 1932, pages 363-367.

The paper is one of those presented in the Symposium on Magnetization of the American Physical Society, Sept. 1931. Single crystals of iron grown by a new method with high temperature heat treatments in hydrogen were found to have better magnetic characteristics than single crystals grown at lower temperatures in hydrogen or in vacuum. Experiments show that the improved characteristics were not due to the large grain size but rather to the high temperature hydrogen treatment. It is now possible to produce iron having very high initial and maximum permeability regardless of grain size and orientation. WAT (1)

Beryllium and Aeronautical Construction. (Le glucinium et la construction aeronautique.) Leon Guillet & Marcel Ballay. *Revue de Metallurgie,* Vol. 28, Oct. 1931, pages 525-528.

Pure Be cannot be used for mechanical purposes because it is too brittle. It does not alloy easily with Mg, though claims were made that the Mg-Be alloys possess the strength of steel. It alloys easily with aluminum but the product is not superior to Al-Si alloys without heat treatment and, even in the heat treated condition, it is not superior to Al-Mg alloys. Quenching and aging of Cu-Be alloys, at 820° and 350° C. increases its Brinell hardness from 110 to 425, greatly diminishing the electrical resistance. Be acts in the same manner in Cu-Sn, Cu-Zn and Cu-Al alloys at least in those having a high Cu content. Brinell hardness of 350-400 is produced here by aging at 250°-350° C. Fe-Be alloys containing more than 2% Be are hardened by drawing at 520° C. after 1100° C. quench. The alloys are so coarsely crystalline that their practical usefulness is doubtful. Ni-Fe alloys to which Be is added are free from grain coarseness and, after quenching from 1100° C. followed by aging at 450° C., give a hardness of about 600 Brinell, though their C content may be very low. 1% of Be added to stainless Ni-Cr alloys hardens them in the same way after quenching at 950° C. and aging at 500° C. No data is given regarding the corrosion-resisting properties of these alloys after treatment. JDG (1)

Examination of Beryllium (Untersuchungen über Beryllium). Heinz Borchers. *Metallwirtschaft,* Vol. 10, Nov. 13, 1931, pages 863-866.

7 references. Be does not form a compound with H. It is not affected by dry or moist air or water. Be powder burns in air when ignited with a Mg ribbon, but a larger piece oxidizes on the surface when heated in O which retards further oxidation. Heated in air, it is covered with white oxide and nitride 300° C. below the melting point. At higher temperatures it has great affinity for even traces of O. Be does not combine with A, and is a suitable atmosphere for melting Be. Be readily forms a carbide, which reacts with SiO_2 at about 1400° C. and with Al_2O_3 when molten, forming BeO. BeO is not soluble in Be. 99.7% pure Be has a melting point of 1285° C. The impurities consisted of 0.28% Fe and 0.02% Al. Small quantities of C depress the melting point. At about 1500° C. and 5 mm. pressure, Be volatilizes at a fairly rapid rate. As the oxide and nitride volatilize at about the same temperatures complete purification of Be by distillation is not possible. Brinell hardness of electrolytic Be 280-300, remelted Be 145-150 and refined Be 140. Electrolytic Be is very brittle. Electrolytic Be contains, as impurities, mainly Fe, also Al, Si, Mg, C and gases. C can be removed by holding the metal for some time at 100° C. above its melting point, the carbides sinking to the bottom. Gases can be removed by melting in vacuum and Fe by distillation. Crucibles for melting consisted of MgO coated with BeO. CEM (1)

Photoelectric and Thermionic Emission from Cobalt. Alvin B. Cardwell. *Physical Review,* Vol. 38, Dec. 1931, pages 2033-2040.

The total photoelectric emission from a strip of Co foil excited by the undispersed radiation from a quartz arc was studied during an extended outgassing process and after stable conditions had been reached. The sensitivity rose quickly in the initial period, then decreased to a stable value. A change in the long-wave limit consistent with the change in the sensitivity was observed. Curves were plotted showing the variation of the full arc sensitivity with temperature. At a temperature near 850° C. abrupt changes in these curves were observed. X-ray analyses seemed to indicate that this resulted from a structural change. The long-wave limit for Co which had been cooled suddenly from above 850° C. and which was known by X-ray analysis to have a face-centered cubic structure was between 2967 A.U. and 3022 A.U. (4.25 ± 0.08 volts). A sample which was cooled slowly from above 850° C. and which was known from X-ray analysis to have a hexagonal close pack structure had a long-wave limit between 2757 A.U. and 2967 A.U. (4.12 ± 0.04 volts). A plot of the thermionic current as a function of temperature indicates that there is an abrupt change in the Richardson (A) or (b) and perhaps both at a temperature near 850° C. WAT (1)

The Surface Tension of Liquid Metals. Part IV. The Surface Tension of Mercury. L. L. Bircumshaw. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Aug. 1931, pages 596-602.

The surface tension of Hg has been determined by the method of maximum bubble pressure from 20° C. down to — 37° C. The surface tension seems to pass through a maximum at approximately — 33° C. Ha (1)

Investigations on the Electric Conductivity of Thin Metallic Layers. (Untersuchungen über die elektrische Leitfähigkeit dünner Metallschichten.) G. Braunsfurth. *Annalen der Physik,* Series 5, Vol. 9, 1931, No. 4, pages 385-418.

The specific resistance and the temperature coefficient of the electrical conductivity show irregularities for thin metal layers for which reasons the present investigation was made. The preparation of the thin layers and the methods of testing are described and a theory on the influence of the thickness of the layer is developed on the basis of the test results; a formula expressing this is developed. For the rare metals Pt, Sr, Rh, the absolute thickness of the anomalous layer lies between 2×10^{-8} and 1×10^{-7} cm; for thinner layers, peculiar discontinuity points in the curves occur, due probably to a loosening of the structure. The temperature coefficient decreases with increasing specific resistance. Ha (1)

Theory of the Magnetization Curve of Ferro-magnetic Single Crystals. (Zur Theorie der Magnetisierungskurve ferromagnetischer Einkristalle.) F. Bloch. *Physikalische Zeitschrift,* Vol. 32, Apr. 1, 1931, page 290.

Briefly refers to a paper at the Deutsche Physikalische Gesellschaft, Dresden, 1931, and deals largely with the measurements of Kaya on ferro-magnetic single crystals. (1)

The Photoelectric Properties of Tantalum. Alvin B. Cardwell. *Physical Review,* Vol. 38, Dec. 1931, pages 2041-2048.

Ta was carefully outgassed and its photoelectric properties studied after stable conditions were reached. Heating 1000 hrs. at temperatures up to 2200° K. produced an apparent stable condition of the surface. Curves, showing the variation of the photoelectric current as a function of the temperature, are plotted for different wave-lengths. For wave-lengths near the threshold, there is a great increase in the photoemission with increasing temperature. With decreasing wave-lengths, this variation becomes very much smaller. Extrapolated values from the F (λ) curves show the long-wave limit to be at 20° C., 2750 A.U.; and at 700° C., 2825 A.U. Further heat treatment at temperatures up to 2500° K. produced a final stable condition. Here again are plotted curves showing the variation of the photoelectric current as a function of the temperature for different wave-lengths. In this case, the great increase in the photoelectric sensitivity with temperature for wave-lengths near the threshold becomes smaller as the wave-lengths used decrease, finally reaching negative values for wave-lengths more than 300 A.U. shorter than the threshold value. Extrapolated values from F (λ) curves at 293° K. and 973° K. show the long-wave limit at the respective temperatures to be 3050 A.U. and 3160 A.U. From curves plotted according to Fowler's theory, the true threshold wave-lengths were found to be as follows: (1) for Ta in first apparent stable condition (average) = 2742 A.U. (4.50 volts). For Ta in final stable condition (average) = 2974 A.U. (4.15 volts). WAT (1)

PROPERTIES OF FERROUS ALLOYS (3)

The Physical Properties of Manganese Sulphide with Relation to its Effects in Steel. EDWARD C. KREKEL. *Colorado School of Mines Quarterly,* Vol. 25, Oct. 1931, 30 pages.

The publication is a thesis and is a tribute to the memory of the author, who died suddenly Aug. 10, 1926. The melting point of manganese sulphide is very high, at least well above 1600° C. Manganese reacts with iron sulphide to form manganese sulphide and iron. The reversibility of this reaction has not been verified. Manganese sulphide and iron form a eutectic mixture. It is probably this eutectic which is the substance commonly mistaken for manganese sulphide in steel. The compound $Fe_3Mn_2S_5$ as formulated by Rohl very possibly exists, but it is unlikely that this is the substance which occurs in steel. The preparation of manganese sulphide is described and the conclusions are illustrated with a number of micrographs. WAT (3)

Fe-Mn-Ni-C, a New Manganese Steel. JOHN HOWE HALL (Taylor-Wharton Iron & Steel Co.). *Metal Progress,* Vol. 20, Nov. 1931, pages 69-72.

A modification of Hadfield's manganese steel with 3½% Ni and approximately eutectoid C content is described and its properties discussed. The ease of working and the weldability of this new alloy are stressed. WLC (3)

Several Grades and Uses of Bessemer Steel. Correspondence from B. GRINDAY, Youngstown, Ohio. *Metal Progress,* Vol. 21, Jan. 1932, pages 70-71.

The writer directs attention to some neglected possibilities of Bessemer steel which has greater ductility, better machining qualities and wider range of analysis than is generally realized. WLC (3)

The Hadfield Manganese Steel; Its Structure and Properties (Der Hadfield-Manganstahl; sein Gefüge und seine Eigenschaften). G. GUZZONI. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 6, 1931, page 868.

The structural conditions of this steel are examined. With very rapid cooling, a complete austenitic structure is possible. When annealed, the austenite is converted directly into troostite. At the same time, hardness and brittleness increase and magnetism is restored. The important factors for the formation of the structure were determined. The austenitic structure is closely related to the best properties of the Hadfield Mn steel. Its principal quality is the high resistance to wear. The Brinell hardness is 500. Ha (3)

The Strength of Cast Iron in Relation to Thickness. P. A. HELLER. *Foundry Trade Journal,* Vol. 45, Oct. 15, 1931, page 243.

Extended abstract of article which appeared in *Die Giesserei* (1931, Vol. 18, pp. 237-241). It is accompanied by 3 diagrams. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 3. OWE (3)

Austenitic Cast Iron. J. E. HURST. *Foundry Trade Journal,* Vol. 45, Oct. 15, 1931, pages 237-239.

The author describes the properties of a 15% Ni-7% Cu austenitic iron cast by the centrifugal process and containing varying quantities of Cr. Increasing quantities of Cr hardened the material, the ultimate strength and modulus of elasticity being increased. The stress at which substantial permanent set is taken up is raised, but the magnitude of the permanent set is lowered. The effect of initial stress tends to increase the stiffness, raise the limit of proportionality, and decrease the liability to subsequent permanent set and deflection. The strength properties are satisfactory in alloys containing up to 4.21% Cr. The iron becomes unmachinable at 7% Cr. Heat treatment has very little effect on the Brinell hardness of these alloys but the strength properties are generally improved, the improvement increasing as the Cr content of the iron increases. Quenching definitely increases the ductility of the high-chromium materials. The coefficient of expansion of an alloy containing 15.13% Ni, 6.95% Cu, 2.75% Cr, over a temperature range of 650° C., was found to be 1.89×10^6. The alloys possess good corrosion- and heat-resisting properties. The article is accompanied by 3 tables and 7 figures. OWE (3)

Iron-Tungsten-Carbon System. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress,* Vol. 20, Dec. 1931, pages 75, 83, 99.

The writer reports on a study by Shuzo Takeda on Fe-W-C system. Equilibrium diagram is reproduced on page 75. WLC (3)

The Manufacture and Testing of Forging Quality Steel. NORMAN L. DEUBLE. *Iron & Steel of Canada,* Vol. 14, Dec. 1931, pages 179-181, 190.

Article, accompanied by 6 macrographs, reprinted from the Sept. 1931 issue of *Heat Treating & Forging.* See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 3. OWE (3)

Tests Indicate Thick Steel Plates Meet Specification. F. O. DUFOUR. *Engineering News Record,* Vol. 107, Oct. 29, 1931, pages 689-690.

Results from about 2 doz. coupons from 2 1/16 in. plate rolled from a single ingot show uniform yield point and ultimate strength varying from 53,800 lbs./in.^{2} at the bottom to 60,800 lbs./in.^{2} at the top of the plate. The variation is due to a segregation of non-ferrous elements in the top part of the ingot. This segregation is accompanied by a variation in physical properties: from the bottom to the top of the plate, with increasing percentages of C, Mn, P and S; there is, likewise, an increase in the yield point and the tensile strength and a decrease in ductility. These relations are shown in tables. Ha (3)

The Valuation of Cast-Iron According to Brinell Hardness. (Die Bewertung des Gusseisens nach der Brinellhärte.) CHR. GILLES. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 27, 1931, pages 894-898.

A further discussion of the relation of rating of cast-iron according to hardness to wall thickness again leads to the conclusion that the Brinell hardness permits only a limited measure for strength and the resistance to wear of cast iron; it is of a certain value only in the case of a pearlitic structure with a very fine distribution of graphite. But it is very difficult to produce such structure. The founder generally knows by experience what kind of a cast iron he has to supply for the dimensions of the piece in question. Ha (3)

Stainless Iron and Steel. J. H. G. MONYPENNY. Second Edition. John Wiley & Sons, Inc., New York, 1931, Cloth, 6 x 9¾ inches, 575 pages. Price $7.00.

The first edition of this book, published 5 years ago, was exhausted in 2 years. Not only the increased size of the book but also the greater clarity with which the reasons for the behavior of the steels are discussed, bear witness to the recent rate of progress in the knowledge of the chromium and chromium-nickel steels.

The treatment is very complete. In discussion of heat treatment, corrosion, and high temperature properties, for example, the reader's memory is refreshed on the general theory before the specific case of stainless steel is dealt with. The work of metallurgists in many countries is culled and all available information is brought in to supplement the author's own wide experience in this field. The result is an extremely useful monograph. It will be the first book to look in for information on these alloys and its existence will save time that would otherwise have to be spent in going through the very extensive literature of the subject.

The advantages of these steels are of course prominently set forth, but the disadvantages and difficulties are equally frankly given. It is written in the scientific vein.

The information is confined to wrought steels, data on cast steels being rather conspicuously absent, which seems odd in so comprehensive a monograph.

The structure and mechanical properties of the plain chromium steels are dealt with first, then the effect of nickel and that of other alloying elements in both the plain Cr and the Cr Ni types. The effect of variations in composition and heat-treatment, corrosion resistance, high temperature resistance, and manufacture and working are discussed from the point of view of the whole group of steels.

Some of Monypenny's specific comments are particularly interesting. He points out that acid "corrosion tests" for material to be subjected to other corrosive media or to atmospheric exposure are very likely to lead to erroneous conclusions. The claim that 0.07% C is a limiting value below which intergranular brittleness is avoided in the 18-8 type, is denied, and 0.03% given as a more probable value. The addition of W, Ti, or V, may retard, but does not eliminate carbide precipitation. Mention is made of the addition of Si plus a heat-treatment designed to precipitate the carbide deliberately, which may be effective.

The utility of short-time high-temperature tensile tests, as a preliminary to creep testing, is emphasized. Monypenny is not enthusiastic about Hatfield's "time-yield" test, pointing out that the rate of creep does not become constant in the time allowed in the Hatfield test, and that the indication of the time-yield data in respect to 18-8 are at variance with reliable creep data. The discrepancies in creep data themselves obtained by various investigators are greatly smoothed out if the data for alloy steels are referred to each investigator's own data for mild steel, and since engineers are acquainted with the service behavior of mild steel at high temperatures, they can appraise the real possibilities of the alloy steels in service quite accurately by comparison.

In discussion of properties after long exposure to elevated temperatures, it is stated that some Ni Cr Mo steels that appear free from temper-brittleness on short-time tests, show it after several months at 400°-450° C.

Although the thermal conductivity of the stainless steels is low, in most cases where heat-transmission is involved other thermal resistances than that of the metal parts themselves are the controlling factors, so that low conductivity is seldom a real drawback.

Even the metallurgists not especially interested in stainless steels will find the book of much value from the general metallurgical viewpoint. Those who are interested will find it indispensable. H. W. Gillett (3)-B-

Steel and its Heat Treatment for Parts that must Resist Wear. H. W. MCQUAID. *Heat Treating & Forging,* Vol. 16, Sept. 1930, pages 1159-1162, 1164.

Discussion of the relative status and economy of the different steels and treatments which can be used where a hard surface is required; some classifications according to their relative costs. The grain size has an important bearing on the machining properties and distortion in heat treatment. This should be taken into account when specifications are made for a certain purpose. Ha (3)

High Carbon, High Chromium Stainless. H. T. MORTON & I. A. RUMMLER. (Hoover Steel Ball Co.) *Metal Progress,* Vol. 21, Feb. 1932, pages 49-52.

The authors present a study of 1.0% C and 17.0% Cr stainless steel for valve parts used in oil lines. Forging must be done in the range 1850-2200° F., followed by normalizing from 1600° F. Shearing, if any, must be done hot, 1900-2100° F. This steel absorbs heat slowly and care must be exercised in all heating operations to be certain of complete and uniform heating of the material. Slow solution of the Cr carbides makes a temperature of 400° F. above the critical necessary in the hardening of the alloy. Full hardness of 59-63 C Rockwell is obtained by quenching from 1900-1925° F. After tempering up to 800° F. cooling may be slow or rapid above 1100° F. it should be followed by quenching. Range 825°-1075° F. should be avoided for drawing, as a brittle condition results. Charts of properties and micrographs illustrate the paper. WLC (3)

Further Data Required on Tough-Hardness of Steel. E. F. LAKE. *Steel,* Vol. 88, Mar. 26, 1931, pages 42-44.

The usual physical tests do not give a correct view on the tough-hardness of a steel; impact tests seem to be the best to judge toughness. Steels for moving parts show usually best results when hardened correctly and drawn at temperatures between 700° and 800° F. Cr-Ni alloys show the necessary properties to the best degree. Ha (3)

The Development of Alloy Steels. C. E. MACQUIGG. *Mining & Metallurgy,* Vol. 11, Dec. 1930, pages 578-580; *Heat Treating & Forging,* Vol. 17, Feb. 1931, pages 151-152, 154.

A brief outline of the views of the present and the past concerning the composition and use of alloy steels. Ha (3)

The Manufacture of High-Grade Castings in the Brackelsberg Rotary Furnace. PETER M. MACNAIR. *Foundry Trade Journal*, Vol. 45, Dec. 17, 1931, pages 377-381.

A description of the methods adopted for obtaining low C iron by means of the Brackelsberg rotary furnace, together with a description of the mechanical properties obtained. The article is accompanied by 3 tables, one of which gives particulars of the relative melting costs of iron produced in the cupola and in the Brackelsberg furnace. The following advantages for the Brackelsberg furnace are summarized: (1) Low C content, giving fine graphite distribution with good tensile and shock properties with ease of machinability; (2) freedom from nuclei, giving fine graphite distribution and a small grain size, thus giving superior mechanical properties; (3) control of Si, S, P and Mn, giving any type of desired metal; (4) sound castings, giving superior mechanical properties and reducing wasters; (5) homogeneous metal, giving same composition throughout castings; (6) ease of adjusting composition of metal, if required, before casting; (7) hot metal, giving sufficient fluidity to cast very thin sections; (8) suited for manufacture of alloy cast irons, giving homogeneous metal with minimum oxidation losses of expensive alloying elements; (9) low C, fluid metal, suitable for malleablizing by the whiteheart or blackheart process. OWE (3)

The Upper and Lower Yield Points of Structural Steel (Om övre och undre sträckgräns hos byggnadsjärn). AXEL LUNDGREN with additions by ARVID JOHANSSON & G. MALMBERG. *Jernkontorets Annaler*, Vol. 114, Oct. 1931, pages 493-544.

When the stress is continually increased up to a certain point (the upper yield point), within the yield range of the load-extension diagram, it generally falls down to a certain lower value. The lowest stress obtained within the yield range is called the lower yield point. A Swedish Government Committee recently proposed the insertion of specifications concerning the yield point for structural steel, and the experiments were undertaken to determine the influence of test piece dimensions and traction velocities in order to arrive at a rational basis for the proposed specifications. No marked relation was found between the dimensions and the load extension diagram, but plate materials gave very little difference between the upper and lower limits, and the round test pieces gave irregular results. The relation between the breaking limit B and the upper yield limit S_o and lower limit S_u varies from $\frac{S_o}{B} = 61\% - 72\%$ and $\frac{S_u}{B} = 51\% - 61\%$. For a steel containing 0.10% C the breaking strength of 22 kg./mm.[2] is recommended and for a steel of 0.25% C 26 kg./mm.[2]; a tolerance of 5% is allowed. Traction velocities corresponding to an increase of stress of less than 30 kg./mm.[2] gave consistent results. The best strength is obtained when the steel is finished at 400°-500° C. HCD (3)

The Influence of Pickling and Zinc Coating on the Tensile Properties of Drawn Steel Wire (Der Einfluss des Beizens und Verzinkens auf die Festigkeitseigenschaften von gezogenem Stahldraht). H. VAN DE LOO, W. PÜNGEL & E. H. SCHULZ. *Stahl und Eisen*, Vol. 51, Dec. 24, 1931, pages 1585-1590; *Mitteilungen Forschungs-Institut der Vereinigten Stahlwerke*, Vol. 2, 1931, Report 7, pages 113-148.

9 wire ropes of the same C content and the same diameter were drawn with different force and subjected to pickling tests, tempering tests and galvanizing tests in order to determine the effect of these treatments on the properties of the finished galvanized wire. The results can be summarized briefly. (1) Pickling tests. HCl produces, in all concentrations, considerably less brittleness than H_2SO_4; with HCl, only a decrease in the number of bendings and twistings is noted, while the H_2SO_4, tensile strength, elongation, bending and twisting are reduced; the latter 2, very greatly. The content of C seems to enhance the decrease of bendings, but to impede that of the torsions. Pickling brittleness can be completely eliminated with HCl. After pickling with H_2SO_4, weakly drawn wires recover least. Pickling brittleness can be removed by annealing but the temperatures required have a great influence also on non-pickled wires. Short annealing at between 400° and 500° C. in lead removes the brittleness entirely after pickling with HCl but not with H_2SO_4. (2) Tempering tests in lead and galvanizing. Tempering reduced the strength and increased the elongation in all wires; this increases with annealing temperature and annealing time. Bending and twisting numbers are decreased by tempering. A change of temperature and duration does not exert any influence on the bending number. All properties deteriorate with increasing C content and increasing degree of stretching with the exception of twisting, where the influences could not be clearly defined. Galvanizing exerts, with regard to tensile strength, elongation and springiness, the same influence as tempering. Bending and twisting deteriorate more than by tempering. The decrease is smaller, the more the wire is stretched. The number of bendings is practically independent of temperature, time and C content. The twisting number decreases with increasing temperature and duration and the less, the higher the C content. Examinations of the structure of the layer of zinc did not reveal any influence on the properties of the wire; but with higher temperature a uniform $FeZn_7$ layer could be detected. The practical conclusion is that wire for galvanizing should be pickled in hydrochloric acid. The slight brittleness occurring hereby is eliminated again completely by the heating in the galvanizing process. If pickling is done with sulphuric acid, only strongly drawn wires should be used because they, too, lose the brittleness. In order to obtain satisfactory bending and twisting values, it is advisable to draw down as much as possible a wire which is to be galvanized; a high C content is favorable. The familiar experience of galvanizing as quickly as possible and at low temperature is again confirmed by the tests. All individual tests and test results are thoroughly discussed. 44 references. Symposium on Malleable Iron Castings. C. L. WARWICK. *Proceedings American Society for Testing Materials.* Vol. 31, Pt. 2, 1931, pages 317-387.

Summary prepared by a special committee of the American Foundrymen's Association and the American Society for Testing Materials. Includes discussion. Uses, manufacture and properties of malleable are discussed. Supplementary data shows variations in properties and effect of various factors on strength. Higher strength malleable and cupola malleable are briefly described. Factors in design of patterns for malleable castings are discussed and a résumé of current specifications for malleable is given. The whole symposium has been summarized by Schwartz in *Metals & Alloys*, Vol. 2, Sept. 1931, pages 143-149. In discussion Kelly objected to the statement of the committee that embrittlement of malleable in galvanizing could be prevented by control of chemical composition. Wolf and Meisse said this could be done only by holding P below 0.15% and Si below 0.80%, which is not the case in normal malleable. They also suggested that the average physical properties tabulated by the committee were higher than those of the average malleable if all producers were considered. HWG (3)

Hardness and Wear-Resistance of Piston-Rings and Cylinders (Härte und Verschleissfestigkeit von Kolbenringen und Zylinder). H. LEMKEN. *Deutsche Motorzeitschrift*, Vol. 8, June 1931, pages 366-368.

The author states that hardness alone does not represent the significant criterion for the wear resistance of piston rings and draws attention to American experience. Among various factors, the significance of the micro-structure is stressed. Includes 4 micro-photographs. EF (3)

Comparative Investigations on Lancashire Iron and Low Carbon Steel (Jämförande undersökningar mellam lancashirejärn och kolfattigt stal). TORKEL BERGLUND & ARVID JOHANSSON. *Jernkontorets Annaler*, Vol. 115, Sept. 1931, pages 409-484.

Mechanical, magnetic and electrical resistance tests were made on several low C steels, such as Swedish Lancashire, Lancashire with pig Fe charge, soft steel made in the electric furnace, Flodin Fe, and English and American Armco Fe. Tensile and impact tests were made on hot rolled material and bending tests and Erichsen deep drawing tests on sheets subjected to varying degrees of cold-rolling. The magnetic properties of both cold and hot-rolled materials were studied, while the electrical resistance was measured on cold drawn wire. No decided differences were noted, though the Lancashire iron seemed more uniform than those of extra low C content. The anti-magnetic properties are decidedly better; the coercive force shows very small increase on aging. The value of this property is about twice as great for Armco Fe after aging as for Lancashire Fe. Fe prepared in the C arc shows very erratic properties, possibly because the impurities are not very readily controlled. The Flodin Fe shows a low stretching limit compared to the breaking limit, which is quite similar to the Armco Fe. 11 tables and 75 figures contain the extensive numerical and photographic data. HCD (3)

The Wear of Cast Iron. *Bulletin of the British Cast Iron Research Association*, Vol. 3, July 1931, pages 10-13.

A résumé of the present situation regarding the wear of cast iron. The question continues to occupy the attention of metallurgists and engineers, particularly in the automobile industry, where the higher speeds and greater mileage now prevailing demand that the wear of cylinders and pistons be at a minimum. In addition, modern production methods demand castings that can be easily machined on mass production lines. The Association has set up a simple wear testing machine for carrying out tests under sliding friction and a number of types of iron have been investigated. The difficulty with the wear test, however, is that it is almost impossible to reproduce service conditions in the laboratory test if the results are to be obtained in a reasonably short time. The question of lubrication and local conditions must also play an important part in wear, and many instances of unusually rapid wear are found on investigation to be due to conditions other than the composition and structure of the metal in question. A very popular test for the wear of cast iron is one in which the specimen to be tested is pressed at constant load against a rotating drum made of a standard steel or cast iron. The test may be either lubricated or not and is measured by the loss of weight or depth of wear in a given time or number of revolutions, irrespective of the wear of the steel drum. Tests indicate that a pearlitic condition is most favorable for wear resistance. Additions of Ni and Cr produce more uniform wear at a lower rate than unalloyed castings. Many opinions have been put forward regarding the influence of P on wear. It has been held that the network formation of the phosphide eutectic in good engineering irons result in a bearing metal type of wearing surface in which the hard phosphide network stands out in relief and the softer matrix wears away and with the particles of graphite forms a lubricant. No definite relation can be obtained between wear and Brinell hardness beyond the tendency for harder (pearlitic) irons to give better wearing properties than softer (ferritic) irons. The wear of the softer irons when tested against the same material has been found to be about 8% higher than the harder irons, indicating some connection between hardness and wear. Best resistance to wear seems to be obtained when both moving parts are made of the same material. It would appear that a useful line of research would be the testing of cast iron against a similar cast iron under conditions which enabled the wear of both specimens to be measured. The surface conditions of the specimens before testing could be varied by processes of machining, grinding, lapping, etc., and the results may throw some light on the nature and mechanism of formation of the "glazed" surface which is a feature of cast iron wearing parts. High-Silicon Pig Iron for the Production of Malleable Iron (Hochsiliziumhaltiges Roheisen zur Herstellung von schmiedbarem Guss). A. L. BOEGEHOLD & C. JOSEPH. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, page 868.

The irregularities in the physical properties of malleable iron are investigated. The influence of Sn, V, Cr, Ti, P, O and N are examined, but no positive results were obtained. Ha (3)

Ferromagnetism and Electric Properties. II. Explanation of the Increase of Magnetic Resistance of Ferro-magnetic Conductors of Electrons. (Ferromagnetismus und elektrische Eigenschaften II. Die Deutung der magnetischen Widerstanderhöhung ferromagnetischer Elektronenleiter.) WALTER GERLACH. *Annalen der Physik*, Series 5, Vol. 8, 1931, No. 6, pages 649-662.

The increase of the longitudinal magnetic resistance of ferro-magnetic bodies at constant temperature, at different temperatures and after previous magnetization can be accurately represented by a formula containing the square of the magnetization; the increase starts only above a critical magnetization which is the component of the magnetization in the direction of the magnetic field. Ha (3)

Note on Melting of Electric Furnace Cast Iron for Rolling Mill Rolls (Note sulla fusione di cilindri di ghisa per laminatoi al forno elettrico). L. DELGROSSO. *La Metallurgia Italiana*, Vol. 23, Dec. 1931, pages 1127-1134.

A 15-ton Heroult furnace using Soderberg electrodes melts 12 tons of pearlitic high test iron in 3-4 hrs., at 700 k.w.h/metric ton. The metal is cast at 1250°-1280° C. Loss of Mn and Si is only 10% against 30 to 50% in a reverberatory furnace. The graphite flakes are smaller and more uniformly distributed in the electric furnace iron. Analyses of a dozen heats from the electric and a dozen from the reverberatory are given. The range was total carbon—electric 2.21-2.52%, reverberatory 2.25-2.60%; combined carbon 0.65-0.75%, 0.63-0.75%; Mn, 0.55-1.01%, 0.70-1.21%; Si, 0.96-1.25%, 0.85-1.30%; P, 0.32-0.42%, 0.30-0.40%; S, 0.02% or less, 0.05-0.08%. The chief difference in composition is the lower S content of the electric iron. Test specimens taken from the gates of the roll castings ran 27,000 to 34,000 lbs./in.^{2} tensile for electric and 23,000 to 29,000 for reverberatory iron. Transverse test on 30 mm. diameter 650 mm. bars tested on 600 mm. centers gave 35 to 44 kg./mm.^{2}, 6 to 9 mm. deflection for electric, and 28 to 36 with 3 to 5 deflection for reverberatory. Brinell hardness on the rolls fell off less in the interior of the roll in the electric iron. In service, the electric furnace rolls were used on an average tonnage of 192/mo., the reverberatory on 178, the wear/mo. was 5 to 8 mm. reduction in diameter on the electric and 7-10 on the reverberatory, the electric averaging 11 mos. service against 9 for the reverberatory. Includes 7 figures. HWG (3)

Characteristics of Alloy Steels. I and II. GEO. M. ENOS. *Modern Machine Shop*, Vol. 4, Dec. 1931, pages 9-14; Jan. 1932, pages 14-18, 22-23.

The characteristics as expressed in equilibrium diagrams are explained. Properties and uses of alloy steels and the alloying elements are discussed and the classification by the S. A. E. system is explained. A table showing the ranges of compositions of some alloy steels suitable for dies and tools is added. The effects of alloying elements are explained by diagrams illustrating the structures of simple alloy steels in the fully annealed condition. The particular high-speed steel alloys with Ni, Cr, W, Mo, and the percentages present are discussed and the heat treatment described. Micrographs illustrate the various degrees of hardness. Ha (3)

Cast Iron Today. A. B. EVEREST (Mond Nickel Co., Ltd.). *Welding Journal*, Vol. 28, Mar. 1931, pages 80-83; Apr. 1931, pages 102-109.

Paper before the Institution of Welding Engineers. The nature of cast iron is discussed, together with the influence of the cooling rate and composition. The limitations resulting from varying sections in a casting are outlined, i.e., difference in hardness in thick and thin sections and porosity and openness of grain. Part II. Includes discussion. The development of the use of special irons is discussed, referring first to work on the control of the nature of the carbon and the control of the rate of cooling. The author treats the use of alloys by showing the specific results brought about by Ni, Cr, Cu, Al, Mo, P, and S. AWM (3)

Mechanical Properties of Forged and Cast Steel with High Manganese Content. (Mechanische Eigenschaften von geschmiedetem und gegossenem Stahl mit hohem Mangangehalt.) P. BARDENHEUER & G. SCHITZKOWSKI. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, Report 191, 1931, pages 237-245; *Stahl und Eisen*, Vol. 51, Dec. 17, 1931, page 1575.

The paper gives the results of the investigation of the mechanical properties of steels, containing 0.15-0.4% C and 0.9-3.0% Mn, which were tested in forged and cast state after various heat treatments. The properties were determined at temperatures between —20 to +100° C. In accordance with foreign investigations it was found that Mn contents up to 2% favorably affect the mechanical properties. The high Mn steel is distinguished by a high toughness and high tensile strength. The best properties are found in the forged as well as the cast steel, which contains 0.15-0.30% C. and 1.7 to 1.9% Mn. These steels gave after annealing at 900° C. for 5 hrs., air cooling, repeated annealing at 680° to 710° C. and subsequent slow cooling to room temperature in the furnace the best properties, as given in the following table:

State of Material	Yield Point lbs./in.^{2}	Tensile Strength lbs./in.^{2}	Elongation %	Reduction of Area %	Notch Toughness mkg./cm.^{2}
Forged	49800-64000	85300-99900	25-30	39-69	21-25
Cast	43300-43500	71900-85300	24-26	49-50	12-18

When the Mn content surpasses 2%, the properties, in particular the toughness, decrease the more the higher the carbon content is, and machining becomes difficult. This effect is more pronounced in the cast steel than in the forged steel. In the temperature range —20° to +100° C. the properties are not essentially affected by the temperature. Yield point and tensile strength slowly decrease with increasing temperature. In the forged steel elongation and reduction of area practically show no change, in the cast steel they slowly increase with the temperature. The notch toughness of neither one of the 2 steels shows a distinct dependence upon the temperature. Most of the properties of structural steels with 0.15-0.3% C and 1.7-1.9% Mn are similar to those of the structural Ni and Cr-Ni steels, so that in some cases they may be used instead of these steels. As cast steel this material can, after a suitable heat treatment, be used for the formerly used Ni-Cr alloyed steels. 13 references. GN (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Under-water Corrosion of Copper-Bearing Steels (Ueber die Unterwasserkorrosion des gekupferten Stahls). H. CASSEL & F. TÖDT. *Metallwirtschaft*, Vol. 10, Dec. 11, 1931, pages 936-937.

Contains 3 references. Recent literature on the behavior of copper-bearing steel when completely immersed in water, is discussed; it is somewhat contradictory. The resistance to corrosion of copper-bearing steel is analogous to that of copper plated steel. As the copper layer is porous in both cases it does not provide much resistance to corrosion and the addition of copper to steel for under-water use is purposeless. CEM (4)

Corrosion Resistance of Aircraft Cables With Different End Connections. *Aviation Engineering*, Vol. 5, Dec. 1931, pages 36-38.

The official report of the Deutsche Versuchsanstalt für Luftfahrt describes a very complete investigation on the corrosion resistance of aircraft cables with different end connections. 3 types of wire were used: (1) a steel wire coated with pure Zn by the hot process, as customarily applied for the manufacture of standard aircraft cable; (2) a steel wire coated with pure Cd by the Udylite process; (3) a stainless V2Z-steel wire furnished by Krupp. 3 types of connections were used, sleeve fittings, splices and soldered splices. The sleeve fitting when finished looked very much like the "Tru-Loc-Fitting" of the American Cable Company. Splices were made in the usual way with thimbles. The soldered splices were also made with thimbles, the 2 ends merely being soldered together. This last type of connection is used almost exclusively by the German aircraft manufacturers. It requires considerable skill and experience to manufacture, but is 100% efficient in strength. The splice connection without the solder is from 10-30% lower in strength than the strength of the cable. 4 months of exposure to a salt water spray fog attacked the Cd coated cables less than the Zn coated ones. The stainless steel cables were very resistant to this attack, but do not prove satisfactory when attacked by concentrated hydrochloric acid as is used for making soldered terminals. Zn coated cables with sleeve end connections show 100% cable strength. The bare stainless steel wires are too hard for this process and should be galvanized at the ends prior to applying the fittings. Cd coated wires are too soft to hold the fittings; the Cd should be removed before the fitting is put on with galvanizing substituted at the points of contact. The corrosion resistance of the sleeve fitting is very high. In soldered splices, the hydrochloric acid necessary for the soldering operation, is very likely to promote corrosion, both in the Zn and the Cd coatings. WAT (4)

Data on the Resistance of Metals Suitable for Dies to the Abrasive Action of Plastic Clay. *Glass Industry*, Vol. 12, June 1931, page 127.

The object of the investigation, carried out at the Bureau of Standards, is to obtain data on the relative "wear values" of metals when subjected to abrasion by the continuous flow of plastic clay, such as occurs in dies for molding stiff mud clay columns. The abrasive material is a mixture of 60 parts of plastic clay and 40 parts of silica sand. 15% of water is added and the mass is tempered to a "stiff mud" condition. The volume of the plastic clay-sand mixture extruded through the orifice of the die specimen is constant for all tests and is extruded at a constant volume rate. The extrusion pressures cannot be governed closely inasmuch as they vary over a comparatively wide range for slight changes in the moisture content of the sand-clay mixture. A small decrease in moisture content causes a large increase in extrusion pressure. As the extrusion pressure increases, the wear loss also increases. It was, therefore, necessary to determine the relation between abrasion loss of the specimen and the extrusion pressure so that the comparative wear values could be determined for the different metals and alloys tested. Preliminary tests indicated that the abrasion loss and the extrusion pressure were directly proportional. Later data, however, indicated that the relation is parabolic according to the equation:

$$y^2 = \frac{CX}{K^2}$$

in which:

y = the abrasion loss of the specimen.
X = the extrusion pressure.
C = a constant.
K = the relative "wear value" of the material.

In the following table are given the relative K values, each representing the average of 8 tests. These values are calculated on a basis of unity for the material showing the least resistance to abrasion and represent the relative lengths of clay columns that can be extruded from dies of these materials which will produce the same amount of abrasion loss in each case.

	K
Zinc manganese bronze	1.00
Electrolytic copper	1.72
Rustless steel	7.09
Soft cast iron	7.91
Steel alloy (soft)	8.25
Steel alloy (hard)	8.41
Medium cast iron	9.00
Hard cast iron	9.36
High C steel (hardened)	19.56
Co-Cr-Mo steel (cast)	127.90
Co-Cr-Mo steel (rolled)	148.58
Co-Cr-W steel	334.35

4 tests in duplicate were also made on a sample of nitrided steel. The comparative wear value K for successive tests were 33.61, 26.84, 21.24, 14.50, which indicated decreasing resistance to abrasion as successive layers of the "case hardened" steel were removed. WAT (4)

Review of the Behavior of Aluminum Against Materials of the Chemical and Foodstuff Industries. (Uebersicht über das Verhalten des Aluminiums gegenüber Stoffen der chemischen und der Nahrungsmittel-Industrie.) Compiled by H. BOHNER, H. BUSCHLINGER & H. ROEHRIG. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 3, Sept.-Nov. 1931, pages 301-346.

A very complete compilation of data and experimental results of the resistance of Al and light-metal alloys against organic and inorganic matters, with numerous illustrations of apparatus, tanks, machinery, etc. used in these two industries. Ha (4)

Protection of Pipes against External Corrosion. *Gas Age-Record*, Vol. 66, Dec. 13, 1930, pages 937-939.

Corrosion of Pipes Sub-Committee Report before the Institution of Gas Engineers, Nov. 1930, London, England. External corrosion may be due to contact corrosion of the soil or to stray electric currents and may be prevented by preventing water coming in contact with the metal or by applying a reverse electromotive force so that the metal is either neutral or cathodic. This investigation was concerned only with the prevention of water reaching the metal. 2 methods were used to determine the permeability of protective coatings to water. One, as used by the Gas Light & Coke Co., depends upon a measurement from time to time of the effective electrical resistance of the protective coatings applied to the pipe and immersed in water or solution. This method affords useful information regarding the course of the penetration of water, etc., because, with increasing depth of penetration, the electrical resistance of the protective coating will generally decrease until it reaches a constant value indicating penetration to the underlying iron pipe. The other method, as used by the South Metropolitan Gas Co., depends upon the measurement of the electromotive force developed between the metal of the protected pipe and a copper plate immersed in water or other solution. An electromotive force is developed at once if and when water penetrates to the pipe material. It is also possible to discriminate between penetration through the actual protective coating and penetration to the metal through minute pinholes in the protection. In the latter case the electric current flowing will, owing to the very large resistance in the circuit be very small compared with that flowing when the coating itself has been more completely penetrated. The 2 methods have given comparable results when testing exceptionally good coatings but, for less perfect coatings, the results were not always reconcilable. Specimen curves are given. VVK (4)

The Passivity of Metals. VI. Comparison between the Penetrating Powers of Anions. SIDNEY CHARLES BRITTON & ULICK RICHARDSON EVANS. *Journal Chemical Society*, Vol. 133, Pt. 2, 1930, pages 1773-1784.

The penetrating power of different anions has been compared by the measurement of leakage current at an aluminum anode, with potassium chromate as a film-producing solute. The decreasing sequence of penetrating power for Al is Cl′, Br′, I′, F′, SO_4'', NO_3' HPO_4''. At a lead anode, the order is NO_4'', Cl_3', Br′, I′, HPO_4'', SO_4''. Ha (4)

Acid-Proof and Heat-Resisting Materials of German Origin (Säure- und wärmebeständige Werkstoffe deutscher Herkunft). H. KALPERS. *Korrosion, Beilage zur Chemischen Apparatur*, Vol. 6, Oct. 25, 1931, pages 45-47.

Among a number of special steels, a special cast iron (thermisilid) has proved to be particularly valuable for use as an acid-resisting and heat-resisting material. A comparison shows the following properties:

	Thermisilid about	Ordinary cast iron about
Melting Point	1220° C.	1150° C.
Density	6.9	7.2
Electric conductivity	1.05	1.3-2.0
Heat conductivity, reduced to cast iron	0.5	1.0
Bending strength	21.0	40-50
Sagging	1.0	2.0-2.4
Brinell hardness	290-350	150-250

A table shows the resistance to different acids and other attacking solutions. Ha (4)

High Chromium Steels in the Chemical Industry. F. M. BECKET (Electro Metallurgical Co.) *Journal Society Chemical Industry*, Vol. 51, Jan. 15, 1932, pages 49-52.

A general review of the industrial uses of Cr and Cr-Ni steels. Some recent developments include an alloy of 60% Ni, 20% Mo with small amounts of Mn and V for resistance to HCl; a cast alloy of 60% Ni, 17% Mo, 14% Cr and 5% W for resistance to chlorine and its compounds and also to phosphoric acid; and a cast alloy of 85% Ni, 10% Si and small amounts of Cu and Al for resistance to hot H_2SO_4. The author also announces a new alloy of 18% Cr, 6% Mn, 4% Ni, and 1% Cu. This steel has exceptional deep-drawing properties. It is slightly more resistant to a greater variety of chemical attack than the Cr-Mn-Cu steels and possesses a somewhat higher strength at high temperatures. VVK (4)

Modern Rustless Steels. A. C. ROWE. *Chemical Age*, London, Vol. 26, Jan. 30, 1932, page 90.

Four varieties of stainless steels with the base analyses identical are: stainless steels containing Cu, steels without Cu for tubes, steels with .5 to 1.0% W for parts to be welded where the work can not be normalized after welding and steels containing 3 to 4% Mo for resistance to H_2SO_4. Recent developments include a free-cutting stainless steel with a composition of .05 to .12% C, .25 to .5% Mn, .5% max. Si, 12.5-15.0% Cr, steel sheets veneered with stainless steel of a thickness of .015″ and heavier (an American development), a Cr-Ni steel wire rope to resist salt water or salt air and to operate at temperatures up to 900° C., a Ni-Mo iron for resistance to HCl and a 5% Cr steel for purposes requiring a fairly stainless steel at a lower price. VVK (4)

Field Measurement of the Corrosiveness of Soils. *American Gas Journal*, Vol. 134, Apr. 1931, pages 34-35.

Investigation of the corrosive action of soils on gas pipe lines made by the National Bureau of Standards has resulted in development of apparatus and formulation of a test procedure enabling distribution men to carry out same by measuring the electrical resistivity of most types of soil. MAB (4)

Coatings for Pipes. SCOTT EWING. *American Gas Journal*, Vol. 135, Nov. 1931, page 38.

See previous abstract. Investigations of coatings for pipe lines made by the American Gas Association with the coöperation of the Bureau of Standards covers the testing of specimens of 42 types of coatings in 14 different locations. The first group were removed from 11 locations after 9 months. Some buried by the Bureau of Standards were removed after a period of burial of 6 years. A third group were removed after a period of 17 years. These were prepared and buried by the United Gas Improvement Company. The specimens were subjected to various tests, measurements and inspections at the Bureau laboratory. The results show that thin coatings develop numerous pinholes, thick asphalt coatings do not prevent surface rusting, but do prevent pits. The pinhole test was considered the most satisfactory for determining the condition of the coatings. MAB (4)

Tarnishing of Metal Wares in Freshly Painted Show Cases. (Anlaufen von Metallgegenständen in frisch gestrichenen Auslagekästen.) FREITAG. *Oberflächentechnik*, Vol. 8, Dec. 15, 1931, page 256.

The author points out that drying oil paints form, under the influence of air, traces of formic acid, acetic acid, formaldehyde and acetaldehyde which may change the surface of metallic objects by forming metal oxides. Before using a freshly painted case every trace of such disintegration products of the oil paint should be removed by careful airing. Ha (4)

The Resistance of Copper-Nickel Steels to Sea Action. J. NEWTON FRIEND & W. WEST. *Engineering*, Vol. 131, June 12, 1931, page 774.

Temperature Rise as Cause of Friction Oxidation. (Temperature-erhöhung als Ursache der Reiboxydation.) MAX FINK. *Stahl und Eisen*, Vol. 52, Jan. 14, 1932, page 42.

It had been formerly contended that theory of friction oxidation (rolling oxidation) was once due to sharp increases in temperature at all the points of contact due to friction of the rolls. However, Tomlinson had discovered that the temperature plays only a subordinate part. Two steel rolls were subjected to a friction test of 50 kg. compression force and approximately 1% slip in an Amsler friction testing machine, the steel rolls being washed by a current of liquid air. Within a very short time, after only a low temperature rise, the characteristic dark coating appeared on the turning surfaces of the rolls. The test results thus confirm Tomlinson's view that the appearance of oxidation is not due to a rise in temperature on the contact surfaces of the two rolls. DTR (4)

The Theory of Metallic Corrosion in the Light of Quantitative Measurements—The Corrosion of Iron and Mild Steel. G. D. BENGOUGH, A. R. LEE & F. WORMWELL. *Proceedings Royal Society*, Vol. 134A, Nov. 1931, pages 308-343.

The oxygen absorption method of measuring corrosion which was developed for zinc has now been adopted for iron and steel. 2 types of corrosion-time curves have been obtained in KCl solutions, namely, exponential for weak and linear for strong solutions. Each is associated with a characteristic corrosion product. Hydrogen gas was evolved in all solutions and the proportion of the total corrosion due to this type of action was considerable in all solutions stronger than N/1000. The general shape of the hydrogen evolution-time curves were similar to those for the corresponding oxygen-absorption curves. Micrographic observations were made to supplement the corrosion velocity measurements. The results showed that the characteristic distribution of corrosion over completely immersed horizontal specimens was determined neither by initial air-formed film nor by differential aeration that could occur in stagnant solutions, but mainly by the distribution of a particular form of precipitated corrosion product. The deposits of rust which are usually supposed to behave as oxygen screens and stimulate corrosion by differential aeration do not so behave in any solution stronger than N/1000 KCl. The rust was found to consist almost entirely of ferric oxide and stable magnetic oxide. In very weak solutions in the presence of oxygen the rust was usually built up into coherent mounds which could not act as oxygen screens but gradually reduced corrosion rates. Highly purified iron gave nearly the same rate of corrosion as mild steel in N/10 KCl, but the rate of evolution of hydrogen gas was less. In conductivity water both purified iron and steel corroded at much higher rates than zinc, but in N/10 KCl much more slowly. The main causes of these differences are to be found in the different properties of the corrosion products. WAT (4)

Corrosion Phenomena in Tin Cans (Fenomeni di corrosione nelle scatoli di latta). O. CARRASCO & E. SARTORI. *Giornale di Chimica industriale ed applicato*, Vol. 13, Dec. 1931, pages 557-564.

Recent literature is reviewed with 7 references. 17 sets of observations on e.m.f. of Fe-Sn couples or couples between lacquered and unlacquered specimens of one or both metals are recorded, in electrolytes of citric or tartaric acid plus H_2O_2, H_2S, chlorides, etc. In many cases, the ordinary position of Fe and Sn in the electrochemical series is inverted in such electrolytes and the Sn acts protectively. Oxidizing additions make Sn more electronegative to Fe. Sulphur and H_2S make iron more electropositive. At a given pH in citric acid, chlorides lower the e.m.f. of the cell. Agitation decreases the tendency toward anodic behavior of either electrode. Lacquering of Sn diminishes its basic character without giving it cathodic relation to bare tin. Bare steel vs. lacquered steel, after a time, has the latter anodic. Rolled steel behaves differently from fused, in rolled iron. The latter is always less noble than tin. Theoretical discussion is given on the experimental observations. The authors admit that perforation is more common in lacquered tin coated cans used for acid fruits, but consider that a lesser evil than loss of color and taste in unlacquered cans. They do not approve the use of lacquered black iron without Sn. More attention to quality of steel, care in rolling and use of heavier tin coatings are urged. HWG (4)

Relation Between Pinholes, Electrical Conductivity, and the Protective Value of a Pipe Coating. Scott Ewing (Research Associate Bureau of Standards). *Gas Journal,* Vol. 195, Aug. 26, 1931, pages 488-489.

A contribution to the Distribution Conference of the American Gas Association, Apr. 1931. The measurements and tests which have been made so far indicate that it is possible to determine the protection afforded by a pipe coating with reasonable certainty by measurement of its conductance in a conducting solution after it has been buried. By a study of the canvas pad or some similar device it is believed that a rapid field method could be developed for determining the conditions of a coating on a pipe line. The thin coatings are decidedly inferior to the heavier coatings and it is doubtful if there is ever a combination of costs and circumstances on permanent lines which makes the application of very thin coatings (0.01 in. or less) justifiable. MAB (4)

Remarks on Corrosion Testing from the View-Point of the Designer. (Bemerkung zur Frage der Korrosionsprüfung vom Standpunkt des Konstrukteurs.) P. Brenner. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

Corrosion testing should aim to give the designer data on the behavior of materials and protective coatings under the actual corrosion conditions in practice. Of primary importance are data on the changes of the mechanical properties, as tensile strength, elongation, endurance limit as caused by corrosion. With light metal alloys laboratory corrosion tests have been developed which give results of satisfactory agreement with natural corrosion tests. Corrosion tests with simple specimens are incomplete since the results obtained are unfit to lead to conclusions on the behavior of complicated structural parts. GN (4)

Corrosion of Refinery Equipment. G. Egloff. *Oil & Gas Journal,* Vol. 28, Jan. 2, 1930, pages 42, 127.

Estimated loss due to corrosion of metals in the United States is $1,000,000,000 a yr. In the American Oil Industry alone the corrosion bill for 1928 is estimated at $135,000,000. Growing uses of corrosion-resistant products in the oil industry include Duriron, Everdur, Monel Metal, nickel aluminum, Ascoloy. VVK (4)

Potential Measurements and Solubility Tests on Copper-Tin and Copper-Zinc Alloys. (Spannungsmessungen und Lösungsversuche mit Zinn- Kupfer- und Zink- Kupfer-Legierungen.) O. Bauer. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

Measurements of potentials do not always indicate conclusions to be drawn on the behavior of a metal or an alloy in the electrolyte used. Oxidic layers or metallic deposits affect the results. Corrosion is essentially affected by the access of O, and corrosion in most cases then increases since O acts as a depolarizer. The attack of HCl on Cu and brass ceased when O was excluded. The loss of weight gives no clear picture of corrosion in many cases. This holds in particular for heterogeneous alloys. The determination of the alloying components which have gone into solution is necessary. The gradual change of the chemical composition of electrolytes must be studied in corrosion tests in still solutions, for metal ions going into solution can accelerate corrosion, as has been observed with Cu and brass in HCl. GN (4)

Electrochemical Protection of Aluminum Alloys against Corrosion by the Help of Zinc. (Elektrochemischer Schutz von Aluminiumlegierungen gegen Korrosion mit Hilfe von Zink.) G. W. Akimoff. *Zeitschrift für Metallkunde,* Vol. 23, Sept. 1931, page 249.

Corrosion tests in the Black Sea demonstrated that duralumin in contact with Zn would not corrode even for long periods. The protective action extends over large areas of the duralumin to portions greatly distant from the point of contact with the Zn. An electrochemical explanation is advanced. A Modern Soil Survey with Shepard Rods. Arthur B. Allyne (Southern Counties Gas Co. of Calif.) *Gas Age-Record,* Vol. 68, Aug. 22, 1931, pages 269-272, 282.

Shepard rods are 2 steel cane electrodes, about 36 inches long, bakelite covered except the tips, that support 2 small dry cells and a resistance-meter which measures the resistivity of the soil at the depth the pipe is to be laid. 2 holes are dug about 1 ft. apart with a 2 in. post hole digger to pipe depth. Upon connecting these canes together at the top with a battery wire, a direct reading is obtained in ohm-cm. that is translated into probable pipe life for that location. In general the correlation is as follows:

Rod readings ohm-cms.	Probable life of bare steel pipe years
0 — 1000	0 — 9
1000 — 2500	9 — 15
2500 — 10,000	15 or more

Any soil that gave a reading below 1000 would require heavy pipe protection, between 1000 and 2500 moderate protection and above 2500, light protection or none at all. The Shepard rod appears to be satisfactory for alkali or western soils but not for acid soils. The author describes the survey of their distribution system; one district of the 8 comprising the system was surveyed in 41 days and states that the work will be completed in one to 2 years. VVK (4)

The Attack-Reducing Effect of Sodium-Silicate to Bromide and Chlorine Water and Calcium Chloride Solutions. (Ueber die Angriffsvermindernde Wirkung von Wasserglaszusätzen zu Brom-und Chlorwasser bezw. Chlorkalk-Lösungen.) H. Bohner. *Aluminium Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Sept.-Nov. 1931, pages 347-348.

It has been found that additions of sodium-silicate to the above mentioned solutions lessens or even entirely prevents the corrosive action on Al. Tables showing the effect with various amounts from 0.1 to 15% on various Al alloys are reproduced. Ha (4)

Rust Prevention. (Rostschutzmittel.) A. Bresser. *Oberflächentechnik,* Vol. 9, Jan. 19, 1932, pages 11-14.

The chemical causes and nature of rust (iron-oxides) are discussed and means described to prevent this damage as much as possible. The treatment with phosphate coatings. ("Coslettize" and "Parkerize") is explained; it consists principally in dipping the well cleaned articles in a boiling bath of phosphoric acid and iron phosphate. These coats are flexible, the various modifications of treatment are described. Further protection is obtained by coats of bitumina, tars, pitches, gutta percha, rubber, natural and artificial resins; silicium-tetra-chloride, nitriding and chroming are briefly discussed. Ha (4)

Artificial and Natural Formation of Protective Layers in Water Pipes (Ueber künstliche und natürliche Schutzschichtbildung in Wasserleitungsröhren). L. W. Haase. *Gas und Wasserfach,* Vol. 74, June 13, 1931, pages 572-576.

Refers to pipes for hot and cold water and considers mainly the behavior of iron, lead and copper pipes. EF (4)

The Corrosion of Aluminium Alloys. Henry Gibb. *Metal Industry,* London, Vol. 40, Jan. 8, 1932, pages 27-30, 34.

Strips of Al alloys, cast both before and after being treated with Cl gas, were placed at the sea shore so that they were submerged by each tide. The strips were cleaned at regular monthly intervals for 6 months. Tables give the results in loss in weight. An alloy containing 84.28% Al, 14.40% Zn, 0.39% Si, 0.48% Fe, 0.50% Cr was the most resistant, losing 1.7 mg./cm.^{2}/400 days. Pb and Si are suitable addition elements but calcium silicide is not. Al alloys containing Cu in excess of 2.5% are unsuitable for corrosion resistance. Gassification increases the resistance to corrosion of the Al-Zn-Cr alloys with the exception of those containing 5-8% Si and 0.1% Ca. PRK (4)

Methods and Apparatus for Testing Corrosion Resistance of Metals. (Über Methoden und Apparate zur Korrosionsprüfung von Metallen.) G. Gollnow. *Die Chemische Fabrik,* Vol. 4, Aug. 5, 1931, pages 326-328; Aug. 12, 1931, pages 335-336.

A review, including 14 references. Loss in weight of samples of metals is determined after immersing them in the corroding solution for a long period or in a solution of greater strength for a short period. Solutions of acids, salts and H_2O_2 are used. Accelerated tests are made by using a spray or by 2 electro-chemical methods, Duffek's method of measuring difference of potential or Tödt's method. For Al, a solution of 3% NaCl and 0.1% H_2O_2 is suitable. Another accelerated method is to alternately immerse in a solution and expose to the air. CEM (4)

The First Corrosion Symposium. (Erste Korrosionstagung, Berlin.) *Zeitschrift für Metallkunde,* Vol. 23, Nov. 1931, pages 316-319.

Brief account of the first corrosion symposium held by the Verein deutscher Eisenhüttenleute, Verein deutscher Ingenieure, Verein deutscher Chemiker, and Deutsche Gessellschaft für Metallkunde, Berlin, October 20, 1931. RFM (4)

Purpose and Aim of Coöperative Research in the Field of Corrosion and Protection Against Corrosion. (Zweck und Ziel der Gemeinschaftsarbeit auf dem Gebiete der Korrosion und des Korrosionsschutzes.) P. Goerens. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

The paper emphasizes the need of a closer coöperation of all groups interested in the problems of corrosion due to the complicated nature of its problems, in order to avoid unreasonable arguments between producer and consumer, to get a better evaluation and compilation of data referring to corrosion and to give the metallurgist new stimuli to produce new materials. An outline is given by which this coöperation may be effected. GN (4)

Corrosion in Shipbuilding. (Die Korrosion im Schiffbau.) E. Goss. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschrift für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

Deals with corrosion on plates, riveted joints, steam engines, turbine blades, Diesel engines, water mains, etc. GN (4)

Protection of Metals from Corrosion. (Protection des Métaux contre la Corrosion.) J. Glaymann. *L'Usine,* Vol. 41, Jan. 8, 1932, pages 29-31.

The different means of protecting metals from corrosion by electroplating with Cr, Ni, Cd, etc., by chemical means, that is surface treatment by oxygen, phosphates, Al, Pb, etc., are discussed and explained. Ha (4)

Correlating Soil Characteristics with Pipe-line Corrosion. I. A. Denison (Bureau of Standards). *Gas Age-Record,* Vol. 65, Apr. 19, 1930, pages 544-546.

Paper before the American Gas Association Distribution Conference, St. Louis, Apr. 1930. A corrosion soil survey was made of a 32-mile section of a group of pipe lines in the southeastern Great Lakes region. It was found that the corrosivity of the soil was a function of the acidity and drainage of the soil. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA32. VVK (4)

A New Apparatus for Testing Materials for Corrosion and Erosion Resistance (Ein neuer Apparat zur Prüfung von Baustoffen auf Korrosions -und Erosions -Beständigkeit). W. Denecke. *Die Chemische Fabrik,* Vol. 4, Sept. 2, 1931, pages 358-359.

The apparatus consists of 2 vessels, each closed at the top by a stopper and connected near the top and at the bottom by tubes. A stirring device passes through the stopper of the vessel in which the sample is placed, the paddles being below the solution level. The tip of a large burette passes through the stopper of the other vessel and a stopcock is connected to the lower connecting tube, forming a means of introducing or draining out part or all of the solution. By means of the stirrer, the solution can be circulated through the 2 vessels and it is possible to keep it a constant strength or change it at will through the inlet and outlet without removing the sample. CEM (4)

The Corrosive Effect of Gasolines and Motor Benzols on Copper. F. H. Garner & E. B. Evans. *Journal Institution of Petroleum Technologists,* Vol. 17, July 1931, pages 451-463.

Considerable attention has been directed in recent years to the corrosive action that certain motor fuels exert upon the metal parts of the fuel systems of automobile and aircraft engines. Free sulphur has been shown to be an active copper-corroding agent, while certain sulphur compounds containing loosely attached sulphur also cause this formation of sulphide. The problem of detecting and identifying the corrosive elements, with a view to their elimination and of devising satisfactory tests for the detection of corrosive action and the estimation of the amount of deleterious matter present is obviously of interest to the refiner and marketer of motor fuels. A summary of the previously published literature on this subject is given in this paper and is followed by an account of experimental work carried out with the objects of selecting the most satisfactory test for corrosion and devising a convenient and accurate method for the estimation of free sulphur, together with some discussion of the results. WHB (4)

Some Water Works Corrosion Problems. Ira D. Van Giesen (Dep't of Water and Power, Los Angeles, Calif.) *Journal American Water Works Association,* Vol. 22, Jan. 1930, pages 36-48.

Various examples of relatively rapid corrosion are given. An open equalizing tank painted with a water-emulsified asphalt showed breakdown of the paint coating on the north side where it was exposed to the rays of the sun when not covered with water. The heat of the sun had expanded the air particles in the emulsion pushing the coating away from the metal and exposing it to attack. The remedy suggested is covering the tanks and in using other than an emulsified paint unless the paint is emulsified under vacuum. A case of graphitized cast iron, due to stray current electrolysis, showed a surface layer of black, then a layer of yellow, then a layer of brown, and finally the unaltered iron. The analyses of these constituents follow:

	Corroded	Yellow	Brown	Unaltered
Si	7.07 %	6.97 %	2.04 %	1.73 %
Mn	0.51	0.45	0.38	0.37
P	2.22	2.04	0.97	0.83
S	0.023	0.018	0.061	0.060
Combined C	0.32	0.09	0.52	0.65
Graphitic C	11.28	9.15	3.68	2.40

"It would appear that the process of graphitic corrosion calls for an internally stressed cast-iron in which the combined C has a tendency to precipitate out of the solid solution as graphite, and the presence of a highly ionized soil. The primary cause is inherent in the cast iron, and the soil is a secondary factor. The remedy, then, would be a protective coating applied to the surface of the cast iron to insulate it from the soil moisture. This would be efficient only as long as the coating was intact. Better cast-iron is probably a better solution." Cases of corrosion due to dissimilar metals in contact are mentioned with the recommendation that the same metal should be used throughout and if it is necessary to change the type of metal used, to coat the pipes for several feet in both directions from the point of metal-change with asphaltum compound. VVK (4)

The Grounding of Telephone Cable Sheaths to Water Pipes. Ira D. Van Giesen (Bureau of Water Works & Supply, Department of Water & Power, Los Angeles, Calif.). *Journal American Water Works Association,* Vol. 23, Feb. 1931, pages 149-159.

The grounding of noise-producing currents of aerial telephone cables to water pipes has no effect from a corrosion standpoint. These currents have frequencies from 50 to 3000 cycles and their magnitude and energy are small. However, if the locality is served by an electric street railway with the usual track return system, there *may* exist a difference of ground potential between the 2 areas connected by the pipe system and the grounded aerial cable which will result in corrosion. A condenser of sufficient capacity to handle the noise currents and of a sufficiently high potential rating to withstand the direct ground potential connected in the grounding circuit is all that is necessary to prevent corrosion. Service Pipes of Various Materials. R. W. Reynolds (West Palm Beach Water Co.). *Journal American Water Works Association,* Vol. 23, May 1931, pages 658-666.

Data and curves are given for the friction loss of corroded and uncorroded galvanized pipe, cement-lined pipe and copper tubing. VVK (4)

Study of the Couple Fe, FeS. The Passivity of FeS (Étude du Couple Fe, FeS, Passivation de FeS). A. Travers & Jean Aubert. *Chimie et Industrie,* Vol. 26, Nov. 1931, page 1040.

Discussion of the corrosion of iron with reference to attempts to determine the value of the electrolytic compounds formed in steels. Armco iron seems to resist corrosion by S very well, a report of 2 very mild steels having a content of S only up to 0.025%. In testing the corrosion of iron by H_2S, it is very important that the S used in preparation of the sulphide be free from iron. Iron sulphide is passive in oxidizing, especially in a solution of 5% chromic acid but, in a concentrated acid, the sulphur is active and has a potential much higher than iron. Hence, it is necessary, in preparing the H_2S, to have an acid with a concentration high enough to act on the iron to remove the FeS. MAB (4)

Corrosion of Tinned Equipment in the Milk Industry, Causes and Prevention (Korrosion verzinnter Apparate, Ursachen und Verhütung). W. Mohr & M. Schulz. 58 pages, 27 figures. Published by *Milchwirtschaftliche Zeitung*, Stendal, 1930.

Reprint of serial publication in *Milchwirtschaftliche Zeitung* during 1930. A study of black spots on tinned copper used in the milk industry. A long series of experiments is described in detail. It is concluded that the spots form because of solution of Sn and subsequent oxidation of the tin salts. Oxidation may occur through use of sodium hypochlorite as disinfectant, through bacterial action, etc., or by anodic oxidation from stray currents or from cells set up by scratching through the Sn, or the use of untinned bronze parts in connection with the tinned apparatus. Tinning flux not removed, or copper salts in the flux cause a dark coloration, as do SO_2 or H_2S. The best prevention from black spots is careful tinning, including removal of all flux, freedom from scratches and porosity. Good dip tinning, or a combination of tinning by wiping and metal spraying pure tin on the hot first coat, followed by polishing of the sprayed coating, is required. Metal spraying by itself does not give a sufficient pore-free coat. Cd-Zn is alleged to form a better coating but Cd should not be used on surfaces to come in contact with milk products. HWG (4)

Pyrophoric Iron on the Hoops of Acetic Acid Containers (Pyrophores Eisen an den Reifen von Essigbildnern). C. Luckow. *Korrosion und Metallschutz*, Vol. 7, Sept. 1931, page 210.

Attention is called to a phenomenon met with in acetic acid factories, i.e., the formation of basic Fe^{III} acetate which displays pyrophoric properties. EF (4)

The Capacity of Aluminium Articles to Resist Chemical Attack. (Zur chemischen Widerstandsfähigkeit von Aluminiumgeräten.) A. Klepp. *Apparatebau*, Vol. 43, Mar. 20, 1931, page 67.

A low resistance to corrosion of Al articles is always due to a high content of Fe and Si. The use of Al vessels, etc, for organic acids is entirely unobjectionable. Ha (4)

Corrosion of Metals by Phosphoric Acid. Peter R. Kosting & Conrad Heins, Jr. (Bureau of Chemistry and Soils, Washington, D. C.). *Industrial & Engineering Chemistry*, Vol. 23, Feb. 1931, pages 140-150.

The paper contains valuable data on the corrosion of metals by C. P. and crude phosphoric acids. Accelerated corrosion tests were carried out with 52 metals and alloys, under various conditions, using 10%, 25%, 50% and 85% acids. The effect of temperature, aeration, and purity of solution were investigated, and the physical appearance of the metals after exposure was noted. It was found that temperature rise increases the rate of corrosion. In concentrated acid, the corrosion rates of stainless steels suddenly increase near the boiling point. The purity of the acid affects the resistance of metals to phosphoric acid. Products of corrosion tend to increase the corrosion of the special brasses and bronzes. Halogens destroy the passivity of stainless irons and steels and so cause rapid corrosion. As, hydrochloric acid, pine oil, mucilage, and pyridine inhibit the attack of concentrated acid on Fe. Sulphuric acid increases the corrosion rate of Fe, brasses, etc. but cuts down that of Pb. Aeration increases the corrosion of non-ferrous metals and alloys. Bibliography of 50 references. MEH (4)

Methods of Testing the Corrosion of Metals. (Sur les méthodes d'essais de corrosion des métaux). E. Herzog & G. Chaudron. *Comptes Rendus*, Vol. 194, Jan. 11, 1932, pages 180-181.

The authors discuss a paper by J. Cournot (*Comptes Rendus*, 1931, 193, 1337) in which reference was made to the application of mechanical tests after corrosion for the purpose of distinguishing between corrodible and non-corrodible materials. They then point out that they had previously published a description of a method of testing corrosion, in which not merely the loss in weight of the specimen but the alteration in its mechanical properties was made the measure of its resistance to attack. This method of testing consisted in the use of a stamping test (presumably a type of Erichsen test), which enabled a very clear distinction to be made between local and general corrosion in the case of test pieces which had been subjected to attack. This type of test has proved of particular value in the examination of such Al alloys as Duralumin, which have been corroded in seawater. The article is accompanied by 1 table. OWE (4)

Corrosion in Refrigerator Installations (Korrosion in Kühlanlagen). M. Hirsch. *Zeitschrift für die gesamte Kälte-Industrie*, Vol. 37, Dec. 1930, pages 231-233.

Gives information published mainly by the American Society of Refrigerating Engineers. EF (4)

Rust Protection of Wire Products with Cadmium. C. M. Hopp. *Wire & Wire Products*, Vol. 6, Nov. 1931, pages 427-434, 447.

The properties of Cd, methods of application to wire products, the equipment required and recent developments in connection with inhibitors are fully described. The most important is the electrolytic method wherein Cd is electrodeposited on the iron and steel products in a suitable electrolyte. Dipping and spraying can also be employed. As inhibitor in the pickling process, hydrochloric acid is used. The deposit of Cd is very dense and relatively non-porous, so that it makes a good protection against rusting. 10 references. Ha (4)

Non-Rusting and Heat-Proof Chrome-Cast-Iron Alloys. (Ueber nichtrostende und hitzebeständige Chrom-Gusseisenlegierungen.) E. Houdremont & R. Wasmuht. *Krupp'sche Monatshefte*, Vol. 12, Dec. 1931, pages 331-337.

The Fe-C diagram at the presence of very high amounts of Cr is discussed and the causes for the great corrosion resistance explained by the behavior of the chromium carbide Cr_7C_3; a content of about 13% Cr in cast iron shows a remarkable improvement in the corrosion resisting properties. A table is given in which the results with a few alloys of this kind are given when subjected to attack by acids, alkalies and solutions, and also for behavior at temperatures up to 1000° C. A few examples are illustrated of the use of this cast iron in ornamental castings and other commercial ware. Ha (4)

The Preparation of Water for Railroad Use. C. H. Koyl. *Journal American Water Works Association*. Vol. 22, July 1930, pages 912-918.

The history of water softening on American railroads; the prevention of boiler pitting by (1) maintaining 15 gr./gal. caustic alkalinity in the boiler water, (2) coating the inside of the boiler with metallic arsenic and (3) an open feed water heater; the prevention of foaming by the addition of a little castor oil. The Present State of Pipe Protection in Municipal Gas and Water Conduits (Gegenwärtiger Stand der Rohrschutzfrage für städtische Gas- und Wasserleitungen). Kröhnke. *Gas und Wasserfach*, Vol. 74, Dec. 12, 1931, pages 1155-1159.

Requirements to be met with in the protection of pipe lines against physical, chemical and electric influences, and present state of failure prevention. The anti-corrosion information refers mostly to non-metallic coatings. EF (4)

The Economics of Steam Purification. L. F. Kuhman. *National Engineer*, Vol. 35, Aug. 1931, pages 258-262.

The importance of absolutely dry and clean steam in the operation and maintenance of steam lines is noted and examples of destructive corrosion are cited. Ha (4)

Rust in Vinegar Plants (Ueber die Rostbildung in den Essigfabriken). C. Luckow. *Korrosion und Metallschutz*, Vol. 7, Sept. 1931, page 209.

The paper deals mainly with the rusting process of cask hoops and its prevention. The influence of acetic acid in addition to the influence of water and oxygen upon the rusting of iron is discussed. EF (4)

Some Fundamental Considerations of Corrosion in Steam and Condensate Lines. R. E. Hall. *Heating, Piping & Air Conditioning*, Vol. 3, Nov. 1931, pages 943-959.

Presents the results of an investigation, covering a period of a year, into the factors influencing corrosion in steam systems. The investigation includes a study of the raw water and the production, the distribution, and the utilization of steam, with reference to heating systems and appliances only. Data are presented in full showing the extent and constitution of deposits in the heating systems in a large office building and a large hotel in New York City. These deposits were found to originate from the action of corrosion and were found to contain little or no evidence of carry-over from the boilers. The cause of the excessive corrosion was found to be the inleakage of air into the vacuum return system. The amounts of oxygen and carbon dioxide associated with the steam are shown to be insignificant as corrosion agents by the application of the law of Henry and Dalton. The cause of corrosion in heating systems can, therefore, be sought in the operation and, to a small extent, in the design of the systems and not in the quality of the steam used if that quality equals that encountered in these studies. WAT (4)

Some Fundamental Considerations of Corrosion in Steam and Condensate Lines. R. E. Hall & A. R. Mumford. *Heating, Piping & Air Conditioning*, Vol. 3, Dec. 1931, pages 1041-1049.

The factors that control the relations of steam to metal in steam heating systems are thought to be of 2 general types: (1) formation at various points in the utilizing system of troublesome deposits, the origin of which was primarily carryover of boiler water and sludge by the steam; (2) corrosive action, and formation of deposits thereby in the utilizing system, with the question to be answered of what responsibility, therefore, should be borne by the steam furnished by the generating system. According to the generally accepted view, corrosion in all cases comprises a velocity or intensity factor and a quantity factor. The velocity factor is a function of the pH value of water, since the rate of dissolution of iron is dependent on this. The quantity factor is a function of available dissolved oxygen. From the standpoint of elimination of corrosion, the ideal would be zero intensity and quantity factors; since this is impossible in practice, it is necessary to establish for both factors tolerances that provide sufficient limitations to render the corrosive action inappreciable in amount. The lower limit obtainable for dissolved oxygen with a deaerating heater is approximately 0.025 c.c./liter. This value in practice is considered satisfactory. When corrosion does occur in systems, it is usually restricted to well defined areas where special conditions exist. In such cases special remedies are required. Return lines in systems using exhaust steam from reciprocating engines rarely show serious corrosion due to the protection afforded by the oil film, or by the maintenance of high pH value in the condensed steam by the carryover of boiler water. The pH value is practically dependent upon the amount of carbon dioxide associated with the steam, when the water is condensate derived from steam which was generated from alkaline boiler water. In many cases, mechanical changes in the system are advantageous, such as the substitution of copper or brass for steel, care being taken to avoid bi-metallic contacts at the joints. WAT (4)

On the Passivity of Metals. W. J. Müller. *Transactions Faraday Society*, Vol. 27, Dec. 1931, pages 737-751.

Contains 31 references. Quantitative formulae are developed relative to the study of passivity on the basis of the electron theory of metals. Anodic passivity is characterized as a time phenomenon and has a definite upper limit of current density in the case of the metal having a soluble or non-existing film on it. When metal is covered with an insoluble film, "layer polarization" is encountered. In this case the initial current density and passivating period are simply related. Chemical passivation consists either in the evolution of oxygen at the anode or in solution at a higher valency, and can only take place when the current density in the pores of the film exceeds such a definite critical value as causes a change of the underlying metal in the pores. PRK (4)

Soil Corrosion Studies of the U. S. Bureau of Standards. K. H. Logan (Bureau of Standards). *Gas Journal*, Vol. 195, Aug. 19, 1931, pages 435-436.

Attempts are being made to obtain data of immediate practical use to the owners of underground pipe. There are 2 problems involved: the location of corrosive sections and the choice of protection against corrosion. The article discusses the progress made thus far in carrying out the tests, but no conclusions or results have been obtained. MAB (4)

Long Life of Structural Steel Piles. R. C. MANNING. *Canadian Engineer*, Vol. 61, July 7, 1931, pages 25-26.

7 steel trestle highway bridges built about 1900 in the vicinity of Chatham, Ont., were inspected by the author. They had apparently received no attention, were exposed to high and low fresh water, had not been painted and were in excellent condition. Although the surface of the steel was somewhat pitted there was no evidence of serious corrosion. The steel piles were not corroded at the water line or in the area between the present water line and the high water mark, which could be readily seen by the deposit of a light colored silt coating on the piles. VVK (4)

Soil Corrosivity Surveys of Great Value. K. H. LOGAN (Bureau of Standards). *Oil & Gas Journal*, Vol. 30, June 4, 1931, pages 28, 282-284.

Presented before the Division of Production, American Petroleum Institute, Dallas, Texas, June 1931. The variation of corrosivity of soils in the same location is shown by the calculated average life of 3 8" parallel pipe lines placed within a few feet of each other. The average lives were 26.6, 21.3, and 17.1 yrs. Chemical tests for identifying corrosive soils when unsupported by other data have proven rather unsatisfactory. While the presence of large amounts of acids, sulphates or chlorides indicate corrosiveness, corrosion has been found in the absence of these indicators of bad soils. Usually simple electrical tests will serve as well to identify corrosive soils as the more difficult chemical analyses. Among the chemical methods used are those of Holler who used a mixture of iron filings, soil and water and measured the hydrogen evolved and Grodsky in which very thin steel disks are placed in crystallizing dishes filled with soil and maintained at a constant temperature for 2 weeks. Among the electrical tests used is that of Putnam who used a coil of wire in a sample of soil and maintained a potential of 2 volts from one end of the coil to the other. After 96 hrs., the wire was examined for the location of the corrosion and the potential required to cause current to flow through the soil calculated. This apparatus was later modified. A potential of 1.4 volts is impressed across the soil through steel plates and after 10 minutes the current flowing through the soil is measured by a milliammeter. Shepard measured the current discharged from a pipe line. He also designed 2 rods for measuring the resistivity of the soil at the depth of the pipe. A method used by Williams and Corfield is the imposition of an e.m.f. on a piece of pipe placed in soil in a tin can, the loss of weight after a definite time indicating the corrosivity of the soil. A soil rod developed by Legg consists in a steel anode and a copper cathode placed at a definite distance apart, the current developing from the corrosion of the steel being measured by a milliammeter. Most, if not all, of the methods for identifying corrosive soils have been shown by their originators to be reasonably satisfactory under some conditions. None of the methods have been used extensively enough to permit defining their limitations. VVK (4)

An Example of Internal Corrosion in Brass. (Example de Corrosion du Laiton). G. MANDRAU. *Aciers Speciaux, Metaux et Alliages*, Vol. 6, June 1931, pages 293-294.

After a service of 15 yrs., a brass bolt was found subjected to internal corrosion, though no external agent was present to promote a galvanic effect. This bolt exhibited 3 distinct layers which had different compositions, yet the original metal was uniform in composition. The exterior part contained: 96% Cu, 0.56% Fe, 3.2% Zn. The intermediate layer contained: 67% Cu, 0.38% Fe, 32.5% Zn. And the core contained: 57.5% Cu, 0.42% Fe, 41.8% Zn. Microscopic examination revealed the presence of internal corrosion of galvanic origin between the constituents Cu-Zn of brass. GTM (4)

The Significance of the Hydrogen Absorption in the Solution of Iron (Die Bedeutung der Wasserstoffaufnahme beim Lösungsvorgang des Eisens). E. LIEBREICH. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 155, July 1931, pages 123-142.

The phenomena on which Evans bases his corrosion theory of aeration occur in an atmosphere of hydrogen, too. Liebreich, therefore, assumes a catalytic effect of the bivalent corrosion products, the distribution of which is materially dependant on hydro-dynamic currents. The author shows that the bivalent hydroxides originated at the Fe-surface render the potential less noble and result in an accelerated dissolution of the iron. The same phenomenon takes place in diluted 1/10 *N* H_2SO_4 in the presence of H_2 at the surface of Fe covered with fine glass powder. The cathodic overvoltage on corroded iron surfaces was found to be lower than on fresh surfaces; this effect is ascribed to the concentration of the hydrogen liberated. EF (4)

Early Steps in the Development of the Columbia Soil Rod. BUELL B. LEGG (Columbia Engineering & Management Corp.). *Gas Age-Record*, Vol. 67, Jan. 24, 1931, pages 111-118.

The Columbia Soil Rod for determining the corrosivity of soils is described and illustrated and the data obtained, charted. VVK (4)

Two Years' Progress in Corrosion Resistance. J. A. MATHEWS. *Paper Trade Journal*, Vol. 92, Mar. 5, 1931, pages 57-58.

A brief review is given of some of the causes of failures of 18-8 alloys, particularly in the sulphite industry. The latest metallurgical theories are given relative to carbide precipitation, and the need for proper heat treatment of metals is stressed, as well as the chemical composition of the alloys. Means of preventing metal embrittlement is indicated. Ha (4)

The Life of House Connections with Respect to Material, Inside Diameter, and Composition of the Water. (Die Lebensdauer von Hausanschlussleitungen in Abhängigkeit von Material, Lichtweite und Wasserbeschaffenheit.) F. MEYER. *Das Gas- und Wasserfach*, Vol. 74, July 25, 1931, pages 703-710.

Presented before 72nd annual meeting of the Deutsche Verein von Gas- und Wasserfachmännern, June 8-10, 1931. Includes discussion. Old cast iron pipes used in the city of Chemnitz for transmission of water supply are compared with more recent wrought iron piping. The latter had longer life. Since lead and zinc were attacked by the water, copper connections were used in the houses. Samples of the water taken from the supply each year since 1919 were analyzed, and the results are presented in a table. Results are also given of the attack of the water on lead and zinc. MAB (4)

Metallography & Macrography (5a)

The Crystal Structure of Copper Electrodeposited in the Presence of Gelatine. H. KERSTEN. *Journal of Physical Chemistry*, Vol. 35, Dec. 1931, pages 3644-3646.

The author refers to work by Trillat (*Revue de Métallurgie*, Vol. 25, 1928, page 286) who found apparent but not conclusive evidence for a difference in the length of the edge of the unit crystal lattice for Cu which had been deposited in the presence of gelatine from that which had been deposited under more normal conditions. His experiments show that any difference in the unit crystal lattice edge of the 2 types of deposited Cu is less than 0.01 A.U. The article is accompanied by 5 figures and 1 table. OWE (5a)

Results up to the Present Time on the Investigation of Equilibrium Systems in the Production of Steel. (Die bisherigen Ergebnisse der Untersuchung der Gleichgewichts-systeme bei der Stahlerzeugung). FRANZ SAUERWALD, in collaboration with WERNER HUMMITZSCH, (Berlin). *Archiv für das Eisenhüttenwesen*, Vol. 5, Jan. 1932, pages 355-366.

Includes summary of all equilibrium constants and deviations in results, 22 references, 14 tables and 10 diagrams. The following systems were critically examined: Fe-O, Fe-FeO-CaO, Fe-O-C, Fe-Si-O, Fe-Mn-O, and P-S. In many cases the observed results of one investigator are different than those of others, and only in the Mn systems is the number of check values greater, perhaps due to greater number of investigations carried out on Mn equilibrium systems. The writers found it of importance to ascertain for future work whether the law of mass action or a definite equilibrium condition applies, as in the Guldberg-Waage $K = \frac{C_a \times C_b}{C_c \times C_d}$ equation, whether for changes in concentration, the value K remained constant. The Interpretation of the Deformation Texture of Metals (Zur Deutung der Deformationstexturen von Metallen). W. BOAS & E. SCHMID. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 17, 1931, pages 53-56; *Zeitschrift für technische Physik*, Vol. 12, Feb. 1931, pages 71-75.

Assuming that a crystal embedded in a poly-crystalline metal has a deformation differing from that of a free single-crystal, at least 3 systems of translation are involved in the formation of the texture of cubic metals developed in tension and compression. The texture of the rolled metal depends on whether the tensile or the compressive texture predominates. That texture which results is stable under tension in the direction of rolling and compression normal to it. The arrangement is discussed for body-centered and face-centered cubic metals. Ha+HWG (5a)

The Influence of Hydrostatic Pressure on the Critical Temperature of Magnetization for Iron and Other Materials. L. H. ADAMS & J. W. GREEN. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, Aug. 1931, pages 361-380.

Measurements were made of the effect of pressure on the magnetic inversion-temperature (Curie point), 5 ferro-magnetic materials—Fe, Ni, magnetite, a 35% Ni steel and a meteoric iron—were tested in the form of small transformers and subjected to pressure in a water-jacket bomb. The tests show that the effect of pressure on the Curie point is practically nil although the possibility of a slight decrease in temperature with increasing pressure is not excluded. Since the energy change is of considerable magnitude, the volume change accompanying the magnetic transformation is, consequently, zero or very small. The author concludes that the Ni-Fe core of the earth must be far above the temperature at which it could be magnetic because its great volume has no important influence on the earth's magnetic field. Investigations on the Iron-Oxygen System (Untersuchungen über das System Eisen-Sauerstoff). H. SCHENCK & E. HENGLER. *Archiv für Eisenhüttenwesen*, Vol. 5, Oct. 1931, pages 209-214.

Report of the Institute of Metallurgy at the Technische Hochschule Aachen; Doctor thesis of E. Hengler. Since it is practically impossible, because of the miscibility gap, to make iron alloys containing more than 0.2% O; the specimens for this investigation were made by mixing finely ground metallic iron with FeO and compressing this mixture. The transformations of a group of Fe-O alloys, containing 0.072%, 0.11%, 0.15%, 0.16%, 0.21%, 0.25%, 0.29%, 0.42%, 0.58%, 1.07%, 1.80%, 2.55%, 2.82%, 6.2%, and 8.38% O_2 were studied by means of a Saladin apparatus according to Roberts-Austen. The thermal analysis as well as diffusion tests and microscopic examinations show a critical point at the concentration of 0.2% O_2 which is assumed to be the limit of solubility of O in solid iron between A_3 and A_4. Up to 0.2% O_2, A_3 is probably somewhat lowered and A_4 is slightly increased at the most about by 3° C. By determining the melting points, an attempt was made to establish the solidus and liquidus line of the partial diagram FeO-Fe_3O_4. The phase changes in solid state among FeO and Fe_3O_4 were microscopically examined. These results and those of previous investigations were used to re-establish the system FeO with as much as 28% O_2. GN (5a)

The Constitution of the Aluminum-Rich Al-Fe-Si Alloys (Die Konstitution der aluminiumreichen Al-Fe-Si-Legierunger). V. Fuss. *Zeitschrift für Metallkunde,* Vol. 23, Aug. 1931, pages 231-236.

Seeing with Invisible Light. Herbert W. Forster. *Scientific American,* Vol. 146, Jan, 1932, pages 7-11.

Describes the microscopic work on metals carried out at the Bell Laboratories in New York City. A microscope objective of given numerical aperture, when used with light of given wave-length, has some fixed limit of resolution, but the ultra-violet microscope developed by the Bell Laboratories appears to have a potential resolving ability probably greater than twice that of the apochromatic system. Micrographs of steel have been successfully obtained by this method at diameters ranging from 5000 to 9000. The difficulty is that at this high magnification the observer cannot be certain of what he is seeing. The image of the test piece is reflected on a fluorescent screen of uranium glass. By this method the difficulties encountered with ultra-violet light in connection with quartz lenses are corrected. Mention is made of the research in progress at the Bell Laboratories in conjunction with the Western Electric Co. on lead cable sheath in an effort to develop a material that will not deteriorate under severe service conditions. WAT (5a)

Colloid Chemistry—Theoretical and Applied. Vol. III. Technological Applications. Edited by Jerome Alexander. Chemical Catalog Co., New York, 1931. Cloth, 9¼ x 6¼ inches, 655 pages. Price $10.50.

Of the 42 chapters, written by various authors, 7 relate directly to metals. Of these, one by J. Alexander deals with the colloidal state in metals and alloys, chiefly in regard to the so-called "zone of maximum colloidality," and arguing more from the analogy of glass than from metallurgical facts. The amorphous theory is accepted, metals being supposed to contain "iso-colloids." β iron is assumed to be an adsorption compound of α iron dispersed in γ iron. Martensite is called a cementite ferrosol, a colloidal dispersion of iron carbide in iron, and its hardness is taken to be due to surface forces arising from the high state of subdivision. In precipitation-hardened alloys, hardening is ascribed to these forces, not to mechanical keying of slip-planes. This chapter is not written in a very convincing style; many cases where colloidal dimensions doubtless do account for observed phenomena are mixed in with others in which it is straining the point very much to assume that colloids come into the picture. Wherever a colloidal explanation can be thought of, it is given whether it ties in with metallurgical facts or not. The chapter would have been improved by having it censored by metallurgists and about half of it omitted as pure speculation. A chapter on Colloidal Conditions in Metal Crystals, by W. Guertler translated by Jerome Strauss, is a far better statement of the colloid point of view of age-hardening phenomena. The chapter "Colloid Systems in Metallography" by C. Benedicks, defines troostite as pearlite containing cementite in colloidal dispersion, martensite as a homogeneous supersaturated solution. One by K. Honda "On the Well-Known Five Structures in Carbon Steels" classes martensite as a homogeneous solid solution phase, troostite as a colloidal dispersion. Various theories stated by Honda in numerous publications are repeated. Yap, Chu-Phay in a chapter on "The Role of Surface Energy on the Equilibria of Iron and Iron Carbide," ascribes results obtained by Wark as due to his working with a fully martensitic structure (heterogeneous with cementite colloidally dispersed in ferrite). The differences in the location of the Acm line as determined by various workers is ascribed to variations in particle size of the cementite. The author disagrees with the slip-interference theory of Jeffries and Archer. The most satisfactory of the metallurgical chapters is a very short one by U. R. Evans on "The Properties of Thin Films on Metals." The final metallurgical chapter is by J. N. Friend on "The Colloids and the Corrosion of Iron," in which Friend's ideas on this subject are reiterated. Many of the other chapters in the book deal with matters of some interest to the metallurgist, such as those on adhesion, results of X-ray researches, wetting, dispersions, suspensoids, flotation, etc. In general, these are far more clear cut, definite, understandable and acceptable than are some of the metallurgical chapters, probably because in systems that can be studied by the ultra microscope, for example, facts can be assembled in greater profusion than can be the case with the metals, which are non-transparent and where the experimental difficulties in dealing with particles of colloidal size leave much to guess-work. The lack of agreement on many points among the authors of the metallurgical chapters brings out more clearly than does any single chapter, the haziness of the colloidal concepts as applied to metallurgy. In spite of the haziness, many interesting and useful points of view are brought out. H. W. Gillett (5a)-**B**-

The Sub-Crystalline Structure of Ferrite. C. O. Bannister & W. D. Jones. *Engineering,* Vol. 131, May 29, 1931, page 707.

Mainly pertains to the adsorption of ThB^{++} and of Pb^{++} on different Ag compounds. EF (5a)

The Origin of Intersticial Cementite and Its Effect Upon the Mechanical Properties of Soft Steel. (Die Entstehung von Korngrenzenzementit und sein Einfluss auf die mechanischen Eigenschaften weichen Flussstahles.) H. Kornfeld & G. Brieger. *Archiv für Eisenhüttenwessen,* Vol. 5, Dec. 1931, pages 315-322.

Report from the Research Laboratory of the United Steel Works, Dortmund. The conditions of formation of intersticial cementite were studied on sheets, 4 mm. thick, of a soft, killed open hearth steel of the following composition: C, 0.11%; Si, 0.09%; Mn, 0.41%; P, 0.01%; S, 0.03%. The steel was practically free from segregations and showed non-metallic inclusions only to a slight extent. All specimens were normalized at 910° C. for ¼ hr., then stretched in a 50 ton Amsler tensile testing machine by 5%, 10%, 15% and 20%, and then annealed at 740° C., 760° C., 780° C., 800° C., and 820° C. for ½ hr., 1 hr., and 3 hrs. After annealing, the specimens were cooled down to 600° C. with an average velocity of 55° C./hr. Yield point, tensile strength, elongation, reduction of area, notch toughness, structure and grain size were determined. The results are as follows: In accordance with the results of the investigation by A. Pomp & E. Holweg (*Mitteilungen Kaiser Wilhelm Institut,* Vol. 13, 1931, report 171, pages 1-28) it was found that, on the one hand, annealing between Ac_1 and Ac_3 is necessary to bring about the occurrence of intersticial cementite; on the other hand, the crystallization of intersticial cementite is most pronounced with the specimens that have been critically deformed, i.e. by about 15%. The values of yield point, tensile strength, elongation and reduction of area show no peculiarities except in dependence upon the degree of stretching. In considering the results of the mechanical properties individually for the various degrees of stretching, there is no pronounced effect of the annealing temperature apparent, though the values at the annealing temperature between 740° to 780° C. are somewhat lower, and also the longer times of annealing do not remarkably decrease the properties. However, there is a remarkable effect as to the degree of stretching. As to yield point and tensile strength the influence of stretching is as follows: when these properties are compared with those of specimens in normalized state. Stretching by 5% decreases the yield point by 2%, the tensile strength by 9%; stretching by 10%, decreases yield point and tensile strength by 12%; stretching by 15% decreases the yield point by 35% and the tensile strength by 16%; stretching by 20% decreases the yield point by 25% and the tensile strength by 13%. Obviously, yield point and tensile strength are essentially lowered in the range of critical, cold deformation. This effect could not be clearly established with the elongation due to larger fluctuations of the individual testing values. The reduction of area is not affected by the various treatments. The surface appearance of the specimens behaves similarly and the specimens stretched by 5% and 10% is about 30% lower than that of the normalized ones, regardless of annealing temperature and time. The notch toughness of the specimens stretched by 15 and 20% are in the average 50% and 40%, respectively, lower than in normalized state; the lowest values are attained at the annealing temperature of 760° C. In accordance with Pomp and Holweg the authors found no distinct relation between notch toughness and grain size, inasmuch as a specimen with typical intersticial cementite and a smaller grain size may have a lower notch toughness than the same material with a coarser grain but a normal pearlitic structure. When it is thus shown that intersticial cementite decreases the notch toughness it must be stated on the other hand that among the specimens with intersticial cementite, variations of its structure cause the contradiction of the established relation between grain size and notch toughness. Though intersticial cementite in combination with a coarse grain generally decreases the notch toughness, the material does not become brittle in the common sense. However, specimens with intersticial cementite show an increased tendency for brittleness through aging, as determined by stretching and subsequent aging at 200° C. in oil. This increased sensibility for aging in comparison with a normal pearlitic structure is caused, not only by a coarse grain, but actually by intersticial cementite. 10 references.

Contribution to the Thermo-Dynamics of Concentrated Solutions. I. Eutectic Systems. (Beiträge zur Thermodynamic der konzentrierten Lösungen. I. Mitteilungen: Eutektische Systeme.) E. Kordes. *Zeitschrift für physikalische Chemie,* Vol. 158, Sec. A, Dec. 1931, pages 1-34.

Kordes established a relationship between the Van't Hoff equation of freezing point lowering and the "general eutectic equation" which was empirically found by himself at an earlier date. Based on the new relationship, the dependence of the eutectic exponents on the melting point of the pure components and on the differential heat of solution in the eutectic is derived. It is shown that the position of the eutectic point in numerous binary systems can be anticipated by calculations involving the melting temperatures and the melting heat of the pure components. The evaluated eutectic is in satisfactory agreement with the actual eutectic found by experiments. Among the 22 binary constitutional diagrams considered, 7 systems with inorganic components and 12 built up by metallic compounds are met with, while the balance refers to the following binary metal systems: Al-Sn, Zn-Cd, and Sb-Pb.

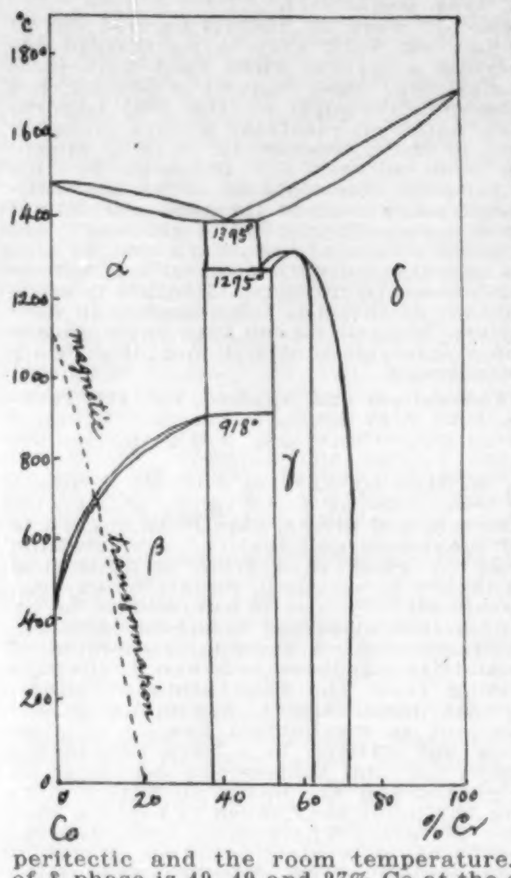
On the Equilibrium Diagram of the Cobalt-Chromium System. Y. Matsunaga. *Kinzoku no Kenkyu,* Japan, Oct. 1931, pages 549 to 564.

The equilibrium diagram of Co-Cr system was determined by means of thermal and magnetic analyses, microscopic examination, dilatation and electrical resistance measurements.



Results are shown in figure. In the liquid state, Co and Cr are completely miscible. In the solid state, there exist 4 phases of solid solutions α, β, γ and δ; α and β phases are solid solutions consisting mainly of Co, the former being a face centered cubic lattice and stable at higher temperature, while the latter is an hexagonal lattice and stable at lower temperatures, γ phase is a solid solution of an intermetallic compound, and δ phase a solid solution consisting mainly of Cr having body centered cubic lattice. α and δ phases form eutectic at 1395° C., 42% Cr. α and γ phases form a eutectoid at 1275° C., 51% Cr. β and γ phases form a peritectoid at 918° C., 38% Cr. The solubility limit of the α phase is 38.5, 38, and 38% Cr at the eutectic, the eutectoid and the peritectoid temperatures, respectively, while that of β phase is 38% at the peritectic and the room temperature. The solubility limit of δ phase is 49, 49 and 27% Co at the eutectic, the eutectoid, and the room temperature respectively. The existing range of γ phase is 62, 57-63, and 58-63% Cr at 1306° C., the eutectoid point and the room temperature, respectively. The magnetic transformation point of Co lowers down to the room temperature at 21% Cr. The hardness, electrical resistivity at the room temperature are also measured.

Martensite Crystallization in High Carbon Steels. (Die Martensitkristallisation in hochkohlenstoffhaltigen Stählen.) Heinrich Hanemann & Hans Joachim Wiester. *Archiv für das Eisenhüttenwesen,* Vol. 5, Jan. 1932, pages 377-382.

Article of the Metallographical & Metallurgical Institut der Technischen Hochschule Berlin. By means of quenching steel test samples in low melting alloys, such as Wood's metal, the homogenous austenite and the separation of martensite needles of high C steels was observed under the microscope. With the aid of systematic evaluation of the annealing operations, the beginning and course of martensite crystallization in steels of 0.83 to 1.69% C were studied in structure. The results were corroborated by magnetic measurement of 3 steels, 0.83, 1.17 and 1.34% C. Austenite is practically non-magnetic, while martensite, on the other hand, is strongly magnetic. Austenite in high C steels from below 200° C. to temperature of beginning of formation of martensite is unusually stable; at higher temperatures, however, it broke down into α-Fe (ferrite) and cementite without martensite conversion. The beginning of martensite crystallization is related to a definite temperature, which depends upon the C content. The course of this crystallization is such that temperature corresponds to an equilibrium between austenite and the η-phase. This $\gamma \rightarrow \eta$ transformation is practically independent of rate of cooling. Hence transformation of martensite is an inherently different process from transformation of austenite into ferrite and cementite; course of this formation proceeds according to its individual actions. Composition of 11 high C steels and temperatures of beginning of η-Fe separation, and magnetic intensities of 3 high C steels are given in tables. Included are diagrammatic curves showing transformation temperature against rate of cooling and effect of C content on the beginning of η-crystallization and 25 diagrams showing structure under all conditions of cooling, annealing, etc.

On the Critical Anisotropic Point of Ferro-magnetic Crystals. (Ueber den kritischen Anisotropiepunkt ferro-magnetischer Kristalle.) N. S. Akulov (University of Königsberg). *Physikalische Zeitschrift,* Vol. 32, Jan. 15, 1931, pages 107-108.

The relative change of electrical resistance for a magnetic crystal under the influence of magnetization is expressed by an equation of the same form as previously given for the change in physical properties. The following law is established: if 2 curves of the relative change of electric resistance vs. magnetization derived for 2 different angles between the magnetization vector and chief axis of the crystal intersect, then the curve for any angle must also pass through this point. Data given by Webster are used for demonstrating an example.

EF (5a)

On the Verification of the Theory of Magnetization of Single Crystals. FRANCIS BITTER. *Physical Review,* Vol. 39, Jan. 1932, pages 371-375.

The paper is one presented in a Symposium on Magnetization by the American Physical Society, Sept. 1931. The theory of magnetization outlined in the other papers of this Symposium makes it possible not only to construct the magnetization curves of single crystals in their principal crystallographic directions, as has been done, but also to predict the magnetization produced by any field acting on a crystal in any direction. The procedure is briefly the following, assume the material to be made up of small regions magnetized to a given intensity, but free to orient their magnetization independently of their neighbors. The potential energy per unit volume of such a region as a function of its direction of magnetization within an unstrained crystal is then expressed in an equation set forth in the present paper for both cubic and hexagonal crystals. The scheme presented herein is capable of representing the main features of the deviation effect in crystals; that certain departures from symmetry which require further investigation are found in some materials; and that studies of the magnetization of single crystals in large fields in the neighborhood of the axes of different magnetization should supplement studies of the initial susceptibility, as both quantities depend on the distribution of magnetized regions differing only slightly in depth. It may further be concluded that fields nearly parallel to a direction of difficult magnetization will probably be found structure-sensitive.

New Method For Measuring Rapidly Alternating Mechanical Forces (Neues Verfahren zur Messung schnellwechselnder mechanischer Kräfte). A. WALLICHS & H. OPITZ. *Stahl und Eisen,* Vol. 51, Nov. 26, 1931, pages 1478-1479.

The article describes a new apparatus for electrically measuring the forces occurring in cutting, turning, planing, sawing, etc. The apparatus works as follows: a measuring box filled with a solution of nitrate of lead is adjusted below the turning tool. The pressure of cutting is taken up by a diaphragm of steel, the elastic inflections of which narrow the cross-section of the liquid and thus increase its electric resistance. This resistance is measured and indicative of the pressure on the point of the tool. A special type of measuring box has been constructed for lathes where the available space is limited.

HWG (6)

The Influence of Shape in Tensile Test Pieces. A. C. VIVIAN. *Foundry Trade Journal,* Vol. 46, Jan. 28, 1932, pages 67-71.

Discusses very completely the view that when cast Fe is tested to destruction, the apparent tensile strength obtained is influenced by the shape of the test piece far more than is generally recognized. When test pieces of large diameter are broken, the comparatively low strength yielded by the test is usually attributed to weak metal in the center of the casting. It is pointed out that there is some reason to believe that when the tensile test piece is pulled, the load is transmitted to the skin of the test piece and then directed toward the center of the section by a species of shear force. Since cast Fe is not a perfectly rigid material, the longitudinal fibres at the center will not be stretched as much as the skin fibres, particularly if the specimen be relatively short and thick. Points out that if the various parts of the specimen are sufficiently long relative to their respective diameters, this shear effect is likely to be negligible, but that in the case of tensile test bars above ½" or ¾" diameter these parts are not made long enough to eliminate the shear effect and its consequent deleterious action on the apparent strength of the iron. The paper deals largely with the correlation of test results from bars of various sizes. The experiments, however, were carried out almost entirely on pieces cut from rubber sheet, the object of the tests being to exaggerate the conditions which are believed to exist within cast Fe test bars. The article is accompanied by 4 tables and 8 diagrams.
OWE (6)

Saving Money by Controlling Flange Wear. C. L. RINN. *Electric Traction,* Vol. 27, Nov. 1931, page 538.

Steel car wheel flange wear has been controlled by the Georgia Power Company, Atlanta, merely by keeping wheels mated in service. The flanges are checked in the car barn and the larger diameter wheel with the thick flange is ground until the diameter is reduced to about 1/64" smaller than its mate with the thin flange. This will create what is termed a floating condition, that is, neither flange lies heavily against the rail, thus modifying the flange wear tendency. 2 metal gages are used in the car barn inspection, one marked "attention," the other "limit." Attention gage fits over a flange that has worn 1/16", and the limit gage 1/8" less than the original or new flange thickness. When the attention gage fits over the flange it means that this wheel is tending toward a thin flange and its mate or the other wheel on the same axle should be ground at the next car inspection period (1,000 to 1,400 car miles). If the limit gage fits over the flange, its mate should be ground within a few days. The grinding is accomplished by means of a pit wheel grinder, without the expense of an automatic welder for building up flanges or heavy car wheel lathes and shop grinders. Car wheels may be used in this manner until the diameter has been down to the motor clearance limit. Diagrams of the gages are shown. Car wheels have still been in service after 180,000 miles, whereas wheels not checked in the above manner had to be replaced after 83,000 miles. Cars on this property are of the 4-motor, double-truck type weighing 38,000 lbs. with 26 in. diameter wheels.

Wires, Ropes, Struts. (Fils, cables, haubans). J. POMEY. *Revue de Métallurgie,* Vol. 28, Dec. 1931, pages 673-689.

Many tests designed for reproduction of the conditions which might be present in actual practice failed to reduce the properties of airplane connecting members to the point of danger or to produce fractures encountered in actual failures. Testing must be conducted on finished articles, but much information can be gathered from the use of a special impact test machine (described) based on the principle of a small impact pendulum or hardness testing apparatus designed for use with wires (described). Tendency is to replace 0.55 C steel with 0.20-0.40 C, 0.8-2.0 Cr and 4.0-5.0 Ni stock. Wires can be checked very well for uniformity by twisting two together. Any non-uniformity will show itself by the difference in the degree of the twist.

Strain Tests on Steel Plates Carrying H-Section Columns. GEO. C. PRIESTER & C. H. SANDBERG. *Engineering News Record,* Vol. 106, Mar. 19, 1931, pages 482-483.

A series of tests were made to illustrate the transmission of a load from a column through a steel plate to an elastic resisting medium. The formulas used for such problems are reviewed; the tests are described and the following conclusions are reached: for square plate, the major portion of the load from an H-column is transmitted to the plate along the flanges of the column; the contact area between the plate and its base is a function of the elastic properties of the base, the thickness of the plate and the location of the application of the load. This area is not a function of the magnitude of the load so long as the foundation is elastic.

Stressing of Material. Conditions for the Ultimate Limit. (Anstrengung eines Werkstoffes. Bedingungen für die zulässige Grenze.) G. D. SANDEL. *Die Wärme,* Vol. 54, May 9, 1931, pages 349-350.

The writer summarizes his paper as follows, "The gradual amount of deformation is characterized as a linear magnitude. Taking an ultimate limit of the amount as the maximum of deformation for each state of stress, a new strength criterion for quasi-isotropic materials is obtained. The anticipations based on theoretical derivations are in fair agreement with actual determinations. If the following definition: 'Equivalent degrees of deformation correspond to equivalent states of stress' is taken as a basis, the ultimate limiting condition is no longer hypothesis but axiom."

Some Tests of Intermetallic Abrasion. H. W. SWIFT. *Engineering,* Vol. 131, June 19, 1931, pages 783-785.

In abrasion testing pressure should be uniform over the surface in contact, the speed of rubbing constant, and means should exist for measuring the amount of wear. The machine used for these tests consists of a cylindrical drum, the flat annular end of which is rubbed against the surface of the specimens under test. Three specimens are tested simultaneously. They are weighed together after every 20,000 revolutions, and the test covers normally from 250,000 to 500,000 revolutions or 350,000 to 700,000 ft. of rubbing. Results are expressed in terms of the mean depth of wear in mils per million feet of rubbing determined from the loss in weight of the specimens, and their density. The following materials were tested: nitralloy steel, gear steel, mild steel, cast iron, phosphor bronze, and "Halo." A table gives results obtained by rubbing specimens of the same material against drums of the same and different materials. In general the results show that a hard material will resist abrasion better than a soft one. Tests give indication of best combinations of materials to be used together where friction is an important factor. Comparison of results shows that for cast iron, the best mating material is nitralloy steel; with mild steel, phosphor bronze or nitralloy should give good results; with gear steel, nitralloy is best; with phosphor bronze, at lower pressures gear steel and at high pressures nitralloy.

Barkhausen Effect: Orientation of Magnetization in Elementary Domains. Richard M. Bozorth. *Physical Review,* Vol. 38, Jan. 1932, pages 353-356.

Since the postulate of the elementary domain by Weiss, and the discovery of the discontinuous nature of the magnetization process by Barkhausen, there have been many investigations attempting to throw more light on the nature of the elementary regions in each of the magnetization changes as a unit. On the experimental side it is of interest to know the sizes of the domains, the extent to which the domain is localized in space, the extent to which it is "saturated" in one direction, and the orientation of its magnetization vector before and after the change. It has been found that nearly all the magnetization takes place in jumps. The evidence set forth herein indicates that the elementary domain is a region well localized in space, within the whole of which the elementary magnets reverse. The paper is one of the Symposium on Magnetization of the American Physical Society, Sept. 1931. WAT (6)

Torsional Stresses, with Plastic Shear. Erik Abt. *Engineering,* Vol. 131, June 5, 1931, page 721.

Short article describing method suitable for solving torsional problems where time is not available for research and complicated investigations. A flexible membrane is stretched across an opening of a form similar to a twisted shaft which is distended by constant pressure. Stresses in any point of the cross section can be determined by measuring the steepest gradient of the distended surface at this point. The volume enclosed between the membrane and the base is a measure of the twisting moment. Maximum shear stress is assumed to be constant when plasticity develops. Diagrams are given illustrating this method of testing. LFM (6)

Magnetization and the Magneto-Caloric Effect. Francis Bitter. *Physical Review,* Vol. 38, Aug. 1931, pages 528-548.

The magneto-caloric effect is defined as the reversible evolution of heat accompanying a change in the magnetization of a ferromagnetic substance, in contradistinction to the irreversible evolution of heat referred to as hysteresis. In two previous notes it was suggested that ferromagnetic substances are spontaneously magnetized in small regions containing roughly 10^5 atoms. Here the following points are briefly discussed: (1) the formation of these units called blocks; (2) the interaction of these blocks to form clusters, which probably give rise to the Barkhausen effect; (3) the changes that take place in the neighborhood of the Curie point; (4) the changes that take place during magnetization. The essential results of the above discussion are that a sudden change in the applied field will produce changes in the energy of every block. The new energy distribution is not stable, and equilibrium is reached by means of an adiabatic diffusion process resulting from thermal agitation, which brings with it a reversible change in temperature. The mechanism is illustrated by means of a simple model. If the strains due to magnetostriction, stray internal fields, and the effect of crystal orientation are neglected, the magneto-caloric effect is amenable to calculation. It is pointed out under what experimental conditions such neglects are justifiable. A detailed comparison is undertaken between experimental observations of the magneto-caloric effect in nickel in high fields and the theoretical predictions based on the assumption that the effect is due to processes involving Weiss' molecular field. The agreement is satisfactory at temperatures not too near the Curie point. Too little is known about the magnetic transformation to permit a quantitative analysis to be made. Akulov's static theory of the magnetization curve of single crystals predicts the absence of a magneto-caloric effect due to rotation of the regions of spontaneous magnetization, i. e., the work done in rotating the magnetization of such a region is equal to its change in potential energy, and therefore there can be no change in heat content. Experimentally this relation is approximately satisfied for Fe and Ni, and less well for Co. If, in the case of Co, the discrepancy is real, a magneto-caloric effect of the order of 0.03° C. is to be expected. The magnetization curves for crystals of Ni and Co on the basis of Akulov's theory are calculated. It is pointed out that experiments on the magneto-caloric effect of single crystals would be of great help in determining the mechanism of magnetization. WAT (6)

Effects of Bending Wire Rope. Frederick C. Carstarphen. *Proceedings American Society Civil Engineers,* Vol. 57, Dec. 1931, pages 1439-1466.

An ever-present suspicion appears in the discussion of wire rope to the effect that the popular formulas for the estimation of the loss of strength due to bending may not be consistent with experiment. This can be settled only by holding the problem up to engineering and analytical scrutiny. This paper is a start along this path. New and more comprehensive formulas are presented, which may serve a useful purpose in bringing to light data and analyses of the problem that have not been published by those who have given their attention to the subject. Wire rope is one of the most used, and most abused, commodities of industry. Therefore, all of its properties should be known, to the end that the public and the wire rope manufacturer may agree upon the increase in its costs, if necessary, to provide for more safeguards in the selection of materials and in the process of manufacture, so that its performance may be predicted for a properly supervised service. Formulas are developed for the bending stresses in various sizes of wire rope while being bent around various sizes of sheaves. Equations are also set forth on the loss of strength as result of such bending. Much of the paper is mathematical. It is shown that a systematic grouping of wires into helices bent about a core may be regarded as having the properties of a yielding foundation. Calculations for loss of strength due to bending wire rope, that are made upon the assumption of pure bending, lead to results that are not satisfactory. Treating the subject from the view point that each strand of the rope is an open-coiled helical "spring" in tension while being bent leads to more satisfactory results. WAT (6)

The Hardening of Metals by Rotating Magnetic Fields. Edward G. Herbert. *World Power,* Vol. 16, Oct. 1931, pages 274-277; *Revue General de l'Electricite,* Vol. 30, July 4, 1931, pages 12-16; *Heat Treating & Forging,* Vol. 17, Dec. 1931, pages 1118-1120.

Experiments are described in which the hardness of various metals is increased by rotating them in a magnetic field. The hardness changes described are believed to indicate a rearrangement of atoms in the space lattice or a change in the atoms themselves, but no explanation is attempted. The time element enters as an important factor into all results produced by the rotating field. The hardness changes are sometimes very rapid, and in a hard steel freshly treated they may be observed from minute to minute. The hardness induced by magnetic treatment is known to persist for months and there is no reason to believe that it is other than permanent, though no systematic investigation has yet been carried over long periods of time. As no metal subjected to the treatment has failed to respond, the possibility must be contemplated that these phenomena are common to all metals. The temperature at which the magnetic treatment is applied has a marked effect on the resulting hardness changes. In the case of hard steel, the treatment is less effective at room temperature than at 100° C., but the latter temperature was arbitrarily chosen and further experiments may show a higher or lower temperature to be more effective. An increase of hardness, such as would indicate an increase of 20% in the tensile strength, has been induced in a soft steel by a single rotation at room temperature; the maximum hardness is attained after 8 hrs. The practical application of the magnetic treatment to hard tool steels is obvious. An increase in hardness from 725 to 820 Brinell was induced in high speed steel by a single turn in the magnetic field, occupying about one minute and applied at a temperature of 100° C. In the non-magnetic metals, the hardness changes produced have been relatively slight. The theoretical importance of these phenomena is believed to be great, but further experiments will be necessary to establish any definite facts. MS+HA+WAT (6)

Material Testing. (Stoffprüfung.) Ernst Lehr. *Zeitschrift Verein Deutscher Ingenieure,* Vol. 75, Nov. 14, 1931, pages 1401-1409.

The present status of material testing is reviewed; the testing methods and their value are discussed for cast-iron, metals at high temperatures, notch-impact tests, vibration strength, metallography. Non-metallic inorganic materials treated are: rocks, cement, concrete, and reinforced concrete; organic materials: asphaltum, wood, and solid fuels. The calibration of testing machines are discussed and values for their accuracy proposed for instance for tensile test machines 1%, hardness testers 2%, vibration testing machines 3-5%. Non-ambiguous definitions are given for elasticity, plasticity, toughness, brittleness, hardness and machineability. Finally, the determination of grain size and distribution of grains in mixtures of loose bodies is discussed and an apparatus for testing colloidal distribution described. 26 references. Ha (6)

The Theory of Wear. (Ueber die Abnutzungstheorie.) H. Friedrich. *Maschinenbau,* Vol. 9, Dec. 1930, pages 781-782.

This is a completion of a paper on the same subject by the author published in *Maschinenbau,* Vol. 9, 1930, page 129. It discusses the further systematizing of the theory, and the results of wear tests. MAB (6)

Influence of Notches on Bars Subjected to Bending Stress. (Kerbwirkung an Biegestäben.) G. Fischer. VDI—Verlag, Berlin, 1932. Paper 6x8½ inches, 164 pages. Price 6.35 RM.

Static bending tests, with the bending moment applied by two-point loading, were made on steel specimens with various notches. The steel used gave 195 Brinell, 92,500-98,000 lbs./in.^{2} tensile, 13 to 15½% elongation, 32 to 45% reduction of area—analysis not given. The specimens were 16.5 cm. long, supported on 100 cm. centers and loaded from above with the loading points 40 cm. apart. The rectangular bar was 11 cm. high and 2½ cm. thick. The notches varied in radius and depth and the Mesnager or Charpy type of notch, like that drilled and saw-cut in an impact bar, and the 60° sharp V or Izod notch were included. The tests were made in static loading. Sensitive strain gages were designed and used to measure the deformation along a line tangent to the base of the notch (parallel to the face of the bar) and normal to this line, at the notch. With these measurements and the use of scribed reference lines, the deformation under load and consequently the distribution of stress, were determined.

The results are expressed in many graphs showing stress distribution, and in those showing the notch coefficient plotted against radius of notch, its depth, or in case of a V notch, its angle. These last are finally assembled in a solid diagram. The Mesnager notch increased the stress something like 3 times, a 60° V "sharp" notch as it would normally be machined, something like 6 to 7 times. Cracks or notches with really sharp bases are calculated to increase the stress 9 to 10 times, although in theory a perfectly sharp notch would make the stress infinite. No tests were made in impact or in repeated bending. H. W. Gillett (6)-B-

Strain and Diamagnetic Susceptibility. H. E. Banta. *Physical Review,* Vol. 37, Mar. 1931, pages 634-637.

The magnetic susceptibility of Cu and Ag has been measured by the Gouy method before and after various annealing treatments. Also, the susceptibility has been measured before and after straining specimens beyond the elastic limit, the strains being either twists or stretches. The susceptibilities are found to be increased by as much as 20% for Cu and 3% for Ag by annealing at red heat for 15 minutes in an atmosphere of CO_2. This increase is probably due to release of occluded gases or to oxidation or recombination of impurities. Straining the specimens beyond the elastic limit is found to produce no measurable change of susceptibility. Francis Bitter has observed a large effect due to straining these metals beyond the elastic limit. The reason for Bitter's results is not clear, but it is pointed out that no effect is to be expected in Cu, at least, because crystals of this metal are isotropic magnetically and have no observed magnetostriction. WAT (6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A.S.T.M. Research Committee on Fatigue of Metals.

Fatigue Testing on Patented and Drawn Steel Wire (Ermüdungsversuche mit patentiertem und gezogenem Stahldraht). A. Lindeberg. *Stahl und Eisen,* Vol. 51, Dec. 17, 1931, page 1573.

In continuing the investigation by A. Pomp and C. H. Duckwitz, *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, 1931, report 175, pages 79-91; *Stahl und Eisen,* Vol. 51, May 14, 1931, pages 620-622, the author briefly reports the results of fatigue tests on ropes which have been processed from wires tested in the above investigation. The rope fatigue tests show that in using common patenting temperatures (furnace temperature 1000° C., lead temperature 550° C.), the best results are obtained with wires of low carbon content (C: 0.43%) and drawn in 6 to 8 drafts with a total reduction of 80-90%. The results, furthermore, indicate that neither fatigue tests nor bending tests of the original wires decide the behavior of the rope in the rope fatigue testing machine. However, the number of twists which the wires stood in testing shows a relation to the results on the rope fatigue testing machine. GN (6f)

Influence of Water Composition on Stress Corrosion. D. J. McAdam, Jr. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 259-278, 13 references, 6 figures.

The effects of corrosion by distilled and by carbonate water in corrosion fatigue tests are discussed. The total damage on some steels at high stress and low cycle frequency may be worse with distilled water than with carbonate water and of 2 metals in the same water, the one that would normally be rated as the poorer in corrosion resistance may show up the better. The data are presented in various types of diagrams, for an understanding of which it is advisable that the many previous publications of the author on this general subject be consulted. HWG (6f)

Tensile Tests and the Fatigue Limit. *Metallurgist,* Mar. 28, 1930, pages 34-35.

This article summarizes a number of formulae for this relation proposed by Striebeck, Herold, and others and comparisons are made with the results of fatigue tests on steel. The results of the investigation can be summarized by the statement that while it is possible to calculate mean values of the fatigue limit from the tensile properties—provided the effect of surface roughness is eliminated as far as possible by grinding—the value so calculated may differ appreciably from measured values, and so can only be regarded as approximate. It would then appear that the endurance test cannot be replaced by a different type of test. (6f)

Endurance of Steel with Rolling Skin, and with and without Holes, and Endurance of Riveted and Welded Structures (Dauerfestigkeit von Stahlen mit Walzhaut von Niet- und Schweissverbindungen). O. Graf. VDI-Verlag, Berlin, 1931. Paper, 6 x 8½ inches, 42 pages. Price 7 RM.

Large flat specimens of structural steels bored with a hole, as for riveting, and with the rolling skin left on, were tested under repeated stress in Amsler tensile testing machines provided with pulsators. Runs were made to 2 million cycles, over a range of stress varying from a given initial tension to a higher tension. The endurance limit of the specimens with holes averaged 61% of that without holes. The endurance ratio of such specimens varied considerably with different steels, and the endurance limit of the stronger steels (80,000 tensile) is not always higher than that of the soft steel (55,000 tensile). No punched holes were used. The range of stress was varied and since the upper limit of usefulness is fixed by the yield point, the high strength steels will stand up better at high initial loads. The effect of the rolling skin was studied on bars without holes. A smooth skin gave results only a few percent below those of carefully polished specimens, but one lot which had fine cracks on the surface had very low endurance limit. Riveted specimens with 3 rivets in each lap gave endurance limits above those of specimens of the same steel tested with one rivet hole but no rivet. Tests were also made on the behavior of rivets. Welded specimens were tested by repeated bending and in repeated tension. In the latter the welded copperchromium structural steel gave a much higher endurance range than ordinary soft steel. Welding is not recommended for structures subject to repeated stress.

Fatigue Properties of Welds. R. A. Weinman (General Electric Co.). *Journal of the American Welding Society,* Vol. 10, Oct. 1931, pages 12-18; Dec. 1931, pages 23-24.

Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Results of fatigue tests of atomic hydrogen welds and weld metal indicate that the behavior of welded structures under fatigue stress does not differ from that of forged and rolled metal. All weld metal specimens built up of mild steel and steels containing small amounts of Cr, Ni and Si showed endurance limits between 22,000 and 30,000 lbs./in.^{2}. Welded samples of mild steel plate varied in endurance limit from 18,000 to 25,000 lbs./in.^{2}; all failures take place outside the weld. Similar specimens made in high tensile strength steel showed endurance limits of 18,000 to 25,000 lbs./in.^{2} and the ratio of endurance limit to tensile strength ranges from 0.3 to 0.4; these all fail through the weld metal. Data is given on hardness of the welds and parent metal and chemical composition of welds. TEJ (6f)

Effect of Surface on the Fatigue Resistance of Spring Steels. G. A. Hankins & M. L. Becker. *Iron & Coal Trades Review,* Vol. 123, Nov. 6, 1931, pages 698-699.

This contains some additional discussion on the subject dealing with changes of the crystalline structure and the magnitude of the decarburized area and cracks. The condition of the surface before the spring is made is of importance and should be ascertained. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 306. Ha (6f)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Preparing Aluminum Alloy Die Castings for Plating. W. E. Warner. *Canadian Machinery,* Vol. 42, Oct. 15, 1931, page 34.

Die castings of aluminum alloy can be satisfactorily plated, provided the surface is first well prepared. The casting should first be cleaned in an alkali bath and rinsed in water. The piece should then be cleaned in a bath consisting of 3 parts of concentrated nitric acid and one part of hydrochloric acid. 10-30 secs. is sufficient to etch the surface so the plating will readily adhere. The actual plating is very similar to plating zinc die castings; the same solutions often are used. Nickel plating is the most satisfactory, and it is usually desirable where other plating is to be employed to first plate with nickel, then deposit the second plate on top of the nickel. By this means any plating can be deposited. The initial plating of nickel has also the advantage that the outer plating need not be so thick as would otherwise be necessary. WAT (7a)

Electroplating Aluminum and Its Alloys. *Electrical Manufacturing,* Vol. 8, Sept. 1931, pages 26-28.

This article developed from material published in a booklet issued by the Aluminum Co. of America, describes how Cr and Zn can be readily plated directly on smooth Al. There is a mistaken idea that Al is a difficult metal upon which to plate. Actually it is as easy to plate as other metals, but does require special methods. A good cleaner has the following constitutents: sodium carbonate (Na_2CO_3) 1 to 3 oz./gal., trisodium phosphate (Na_3PO_4) 1 to 3 oz./gal. Cr can be readily applied directly to Al from an ordinary Cr bath at about twice the usual current density used for plating Ni, requiring for cleaning only a short dip in the alkaline cleaner mentioned above. Zn can be plated directly on a smooth surface of Al, by cleaning in the above solution, rinsing, and dipping for 60 secs. in an acid cleaner. A shorter time produces poor adhesion. The Zn plating bath which has been found to be most suitable for a preliminary "flash" coating is as follows: zinc cyanide $Zn(CN)_2$ 4 oz./gal., sodium cyanide NaCN, 4 oz./gal., peptone ⅛ oz./gal. This solution is used at a current density of from 1-5 amperes/ft.^{2} for from 1-10 minutes. Plating is continued in any plating bath which may be used over Zn. WAT (7a)

How Should Incorrect Working of the Silver Plating Bath be Remedied? (Wie vermeidet man Fehler und Störungen beim Versilbern?) Hans Hornauer. *Deutsche Goldschmiede-Zeitung,* Vol. 34, Aug. 15, 1931, page 350.

Rhodium Plating Process. *Brass World,* Vol. 27, Dec. 1931, page 254.

The H. A. Wilson Co. is marketing a rhodium plating process and equipment for operating it. The process is applicable to the plating of jewelry, silverware and similar articles. Rh is impervious to corrosion and produces a permanently white, hard plate. WHB (7a)

Renewals by Electro-Deposition. *Engineering,* Vol. 131, May 22, 1931, page 676.

Editorial briefly commenting on paper entitled "The Effect of Surface Conditions and Electro-deposited Metals on the Resistance of Materials to Repeated Stresses" by R. H. D. Barklie and H. J. Davies read before the Institution of Mechanical Engineers. LFM (7a)

Electroplating, Polishing and Lacquering of Metals. (Galvanizzazione o Galvanostegie, pulitura e verniciatura dei metalli.) F. WERTH. 5th edition. Ulrico Hoepli, Milan, 1930. Cloth, 4¼ x 6 inches, 812 pages. Price 38 lire.

A rather complete handbook, written primarily from the practical point of view. Many of the illustrations are crude woodcuts from earlier editions. There was a second edition in 1907. Some more modern information is included, such as that on chromium plating, but in general, it is old, of the cook-book type, and not necessarily reliable. It is stated that the roof of the "new" City Hall at Philadelphia is plated with aluminum and that this large scale experiment proves the practical possibility of depositing aluminum from aqueous solutions! There are no literature references, but an alphabetical index is supplied. H. W. Gillett (7a)-B-

Electrodeposited Metal Foils. H. KERSTEN. *Review Scientific Instruments,* Vol. 2, Oct. 1931, pages 649-653.

Metal foils may be produced electrolytically by making use of the fact that electrodeposits do not adhere well to polished stainless steel. An apparatus, methods and plating baths for this purpose are described. Solutions for deposition of Co, Ni, Cu, Ag, Cd, Sn, Au and brass are given. Ha (7a)

New Cadmium Plating Process. *Brass World,* Vol. 27, Dec. 1931, page 256.

"Cadalux" is a new Cd plating process developed and offered by the Hanson-Van Winkle-Munning Co. The claims for it are: a very bright Cd finish, an exceptionally homogeneous and closegrained crystalline structure, excellent throwing power and a very accurate and simple method of solution control. "Nitri-Brite Dip" is a finishing process applicable to articles plated with "Cadalux." It is an acid treatment providing an extremely high additional lustre, which eliminates the necessity of buffing or scratch-brushing with the attendant reduction in susceptibility of the plated surface to finger marks, stains or other discolorations due to handling. WHB (7a)

Nickel Plating Practice Abroad. *Brass World,* Vol. 27, Dec. 1931, pages 251-254.

An abstract of a paper by W. T. Griffiths (Mond Nickel Co. Ltd.) and read before the Electro Platers' & Depositors' Technical Society. Methods of pickling and plating are discussed, as employed at a number of plants in the United States, France and Germany. WHB (7a)

The Electrolytic Production of Seamless Metal Tubes. (Die Herstellung nahtloser Metallrohre auf elektrolytischen Wege.) *Oberflächentechnik,* Vol. 9, Jan. 5, 1932, pages 1-2.

Electrolytic production of seamless pipes has been feasible so far only for comparatively short lengths; the metal was deposited, in the desired thickness, on a rotating core serving as cathode. A new method by Prof. Billiter permits a continuous production of pipes of any diameter. For pipes of 1 to 30 mm. inner diameter the process is the following: a core of Cr steel or an Fe-Si alloy is placed vertically in the electrolytic bath touching the bottom with one end and serves as cathode for the deposition of the metal. At the start, a piece of tube fitting exactly on this core and long enough to protrude from the bath is placed on the core so that it covers only a small part of it. The pipe is made the cathode, the metal is then deposited on the pipe as well as on uncovered part of the core. As soon as the deposition has reached a certain thickness the pipe and with it the thin metal cylinder deposited on the core is raised somewhat so that again a part of the core is uncovered. Metal is now again deposited and so the process goes on. In this manner a seamless tube is made with a thickness increasing step by step from the bottom to the surface of the bath. The interior of this tube is entirely smooth, the exterior shows marks corresponding to the steps by which the pipe was lifted. This method has been tried out for Cu, Fe and Zn tubes. A drawback is the slow production, about 8 cm. tube per hour. This can be increased by a modification to about 80 cm. in one hour by a horizontal arrangement of a hollow cathode. A Cu tube showed a tensile strength of 30 kg./mm.^{2}, elongation of 40% and elastic limit of 18 kg./mm.^{2} The greatest advantages of tubes produced in this manner is the absolute lack of any surface defects which are always present in rolled tubes. This process is said to be particularly suitable for Ni tubes which can be made only with difficulty and at greater cost in other ways. Ha (7a)

New Electrodeposition of Alloys (Neue galvanische Metall-Legierungen). M. WILMER. *Oberflächentechnik,* Vol. 8, Nov. 3, 1931, pages 225-226; Dec. 1, 1931, page 246.

The conditions under which an electrodeposition of alloys can be obtained are discussed. The main factors for the composition of the deposit are the ratio of the metals in the bath, the temperature and the current density. Experimental curves show the change in deposited ratio of Cu and Ni. With increasing temperature, the deposition of Cu increases. A greater influence is exerted by the current density; low densities favor, in all ratios, the deposition of Cu. More recent investigations were made with Ni-Cd alloys, Ni-Fe, Ni-Co; an alloy of 20-30% Co and 80-70% Ni has a pure white color which is obtained by no other electro deposited metal except Ag. An alloy with 25% Co has the hardness of the pure Co deposit. In conclusion, a Ag-Cd alloy is discussed. It is distinguished by its low tarnishing property, especially against atmospheric compounds of S. These alloys assume a greenish appearance like pure Cd, while Ag becomes entirely black. The characteristic curves for all these alloys are given. Ha (7a)

Current Density in Chromium Plating. R. J. PIERSOL. *Metal Cleaning & Finishing,* Vol. 3, Apr. 1931, pages 327-332.

The electrical properties of electrolytes and the magnetic effects in the latter are explained. A diagram is given for the determination of the required voltage for a given current density. Ha (7a)

Historical Survey of Chromium Plating. R. J. PIERSOL. *Metal Cleaning & Finishing,* Vol. 3, Jan. 1931, pages 29-34.

The development from Volta up to 1923 when the Sargent bath made chromium plating a commercial proposition is described. Ha (7a)

The Electrodeposition of Cadmium. (La cadmiatura elettrolitica). F. PIETRAFESA & C. LUCIANI. *La Metallurgia Italiana,* Vol. 24, Jan. 1932, pages 1-9.

The effect was studied of varying the concentration of Cd, sodium cyanide, sodium hydroxide, sodium carbonate and of additions of sodium sulphate, ammonium chloride, mannite, glucose, starch, dextrin, agar-agar, tannin, methylene blue, sodium sulphoricinate, green soap, phenol, licorice and gelatine. The presence of small amounts of Cu, Ag, Mg, Ca, Zn, Hg, Al, As, Bi, Cr, Mn, Fe, Co or Ni in baths containing 2 g./liter of gelatine, normal in cadmium and twice normal in free cyanide, did not affect the Cd deposit, while Sn, Pb and Sb were harmful. The reflectivity of the deposits with gelatine was measured with a Lummer-Brodhun photometer. Cathodic efficiency depends chiefly on concentration of Cd ion, secondarily on that of ions of alkaline metals. Anodic efficiency depends chiefly on the specific effect of the cyanogen ion. Anodic polarization decreases as cyanogen ion concentration increases. Concentration of cadmium ions, and to a smaller degree, of that of alkaline metal ions, controls the character of the deposit. Of the addition agents tried, gelatine is best, but its influence is only temporary. Gray deposits instead of bright ones are obtained when the effect of the gelatine is exhausted. This work has led up to a commercial bath, which will be described in a later communication. 15 references. HWG (7a)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Pure Tinning—A Finish For Hollow-Ware. C. EVESON. *Sheet Metal Industries,* Vol. 5, Aug. 1931, pages 265-268.

A pure tinning unit, called a stack, is described and a detailed description of the tinning of an article is given. There are 5 pots in a stack, namely: (1) thick fat—to cover (2); (2) bulk supply of tin held at about 370° C; (3) pure tin —articles are cleaned in this pot after being rough tinned; (4) pure melted Russian fat—to remove surplus tin; (5) listing pot—a small pot for finishing handles and removing drips. AWM (8)

Galvanizing vs. Rust. *Gas Journal,* Vol. 194, June 24, 1931, page 939.

Review of booklet recently published by Messrs. G. A. Harvey & Co., Ltd., dealing with the cause and prevention of rust and corrosion in iron and steel. The pamphlet describes the "Harco" hot galvanizing process, by which the Zn is definitely alloyed with the surface of the Fe. This coating is composite in character and really consists of several layers merging one into the other, there being no really sharp boundary between the Fe surface and the pure Zn. MAB (8)

Vibration of Dross Affords Higher Zinc Recovery. W. G. IMHOFF. *Steel,* Vol. 88, May 14, 1931, page 41-42.

The amount of Zn which can be recovered from the dross of the hot-galvanizing process can be materially increased by using a vibrator to shake the molten Zn from between the crystals immediately after the scoop has been raised to the surface. The method is described in detail. Ha (8)

Coatings by Aluminum (Der Anstrich aus Aluminium). H. KALPERS. *Dinglers Polytechnisches Journal,* Vol. 345, Apr. 1930, pages 64-67.

The coating technique with Al-powder is reviewed. EF (8)

Mottled Tinplates. J. C. JONES. (University College, Swansea). *Sheet Metal Industries,* Vol. 5, Oct. 1931, pages 408-419.

Includes discussion. The article presents work done in determining the effect of the steel used and of the flux in causing mottled tinplate. The author concludes that (1) the steel base has an effect and is of the opinion that Bessemer steels do not produce mottle (there is some question about the history of the steel, however), and (2) that the use of clean, active flux is necessary. See also *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 12. AWM (8)

Top-Fired Galvanizing Pot Effects Saving in Fuel. W. G. GUDE. *Steel,* Vol. 88, May 28, 1931, pages 36-38.

Description of a gas-fired galvanizing pot. Ha (8)

Centrifugal Process Meets Demand for High-Quality Galvanizing. K. P. ROLSTON. *Steel,* Vol. 88, Apr. 2, 1931, pages 39-42; Apr. 16, pages 39-41; Apr. 30, pages 35-38.

Extracting excess Zn from the surface of small galvanized articles is facilitated by centrifugal means. The different methods, equipment, and the precautions for minimizing the formation of dross are described. Ha (8)

The Spray-Sherardizing Rust-Proofing Process. *Engineering,* Vol. 131, June 5, 1931, page 750.

After brief description of the ordinary dry-vapor galvanizing or Sherardizing process, the new Spray-Sherardizing or Spray-Rust proofing process is described. It is used for coating structural steel after erection is complete. It consists of first coating the surface with a bright-green bitumen-base paint, then applying zinc dust before the paint has completely dried. The process is no more expensive than ordinary paint and is two or three times more durable. LFM (8)

The Development of the Metallic Spraying Process according to Schoop (Werdegang des Metallspritzverfahrens nach Schoop). A. SALMONY. *Dinglers Polytechnisches Journal,* Vol. 345, May 1930, pages 70-71.

The 20 years' history of Schoop's metal spray process is traced. EF (8)

Surface Treatment of Aluminum and Its Alloys. A Survey of Modern Practice. *Chemical Age,* Vol. 25, *Monthly Metallurgical Section,* July 4, 1931, pages 1-2; Aug. 1, 1931, pages 7-8.

A review covering metallic coatings for Al surface coatings by chemical treatment, electroplating and anodic oxidation. VVK (8)

Nickel-Clad Steel Affords Noncorrosive Surface. W. G. HUMPTON, F. P. HUSTON & R. J. MCKAY. *Steel,* Vol. 88, June 4, 1931, pages 44-50.

INDUSTRIAL USES & APPLICATIONS (9)

Aluminum in the Racing Automobile. *Metal Industry*, N. Y., Vol. 29, Sept. 1931, page 379.

Compositions and uses are given of 4 Al alloys used in the racing car "Blue Bird," which established the world record speed for automobiles. PRK (9)

Mercury Vapor Turbines. *Electrician*, Vol. 106, June 19, 1931, pages 908-909.

20,000-kw. units are being constructed for the General Electric Co. and as an extension for the Public Service Electric & Gas Co. A 7500-kw. steam turbo-generator is also included in this extension. These mercury vapor sets will have twice the capacity of the original combined mercury and steam set at the South Meadow Station of the Hartford (Conn.) Electric Light Co. The performance of the latter installation is reviewed. WHB (9)

Aluminum As An Insulating Material. *Fuel Economist*, May 1931, pages 265-267.

Information given for the use of "Alfol," insulating material made from Al foil. Chief and most obvious characteristic is its light weight, adding only 3 oz./ft.^{2} to the weight of a plant. In case of repairs to the plant insulation, the whole of the insulation may be readily renewed and replaced, a real economic advantage. With 4.49 in. diameter test pipe and 2 in. of Alfol insulation, pipe temperature 800° F., the heat lost per °F. difference of temperature in B. t. u./ft.^{2}/hr. was 0.366, or an efficiency of 95%. This material may easily be crumpled. Illustrations of plant installations with Alfol, and heat loss charts are given. DTR (9)

Pewter Ware. *Metal Industry*, London, Vol. 39, July 31, 1931, pages 99-101.

Modern pewter is free from Pb and contains 92.96% Sn with Sb and Cu. The metal is more suitable for individual craftmanship than mass production. PRK (9)

Modern High-Pressure Gages make Use of Special Steels. H. R. Simonds. *Steel*, Vol. 88, Apr. 9, 1931, pages 39-40, 53.

A Cr-Mo steel is used for the spring and nitralloy steel for the movement of the gages. Ha (9)

Die Castings Make Possible New and Redesigned Products. G. M. Rollason (U. S. Aluminum Co.). *Iron Age*, Vol. 128, Nov. 15, 1931, pages 1178-1181.

Die castings play an important part in the construction of new products, due to the attention paid to fabricating costs of dies. Pb, Sn, Zn and Al base alloys are used for die casting. Various products which are made are described. Economies are found in the elimination of machining and finishing operations. Many industries use die castings. VSP (9)

Utilization of Schoop's Metallic Spray Method in Electro-Medicine (Das Schoopsche Metallspritzverfahren im Dienst der Elektro-Medizin). M. U. Schoop & J. von Riess. *Umschau*, Vol. 35, June 6, 1931, pages 459-462.

Textile fabric covered by a metallic spray of Zn is used for flexible electrodes in dia-thermal therapy. 11 illustrations. EF (9)

Standardization of Precision Steel Tubing. (Normung der Präzisionsstahlrohre.) C. Roubaud. *Maschinenbau*, Vol. 10, Mar. 19, 1931, page 210.

Deals with the cold drawn ingot steel tubing which is used in power plants, in aircraft and by railroads, and for which the German Committee on Standards has issued standard specifications. MAB (9)

Turbine Blades Offer New Field for Alloy Steels. H. R. Simonds. *Iron Trade Review*, Vol. 86, April 10, 1930, pages 59-62.

Describes manufacture of blades at Philadelphia works of the Westinghouse Electric & Manufacturing Co. Material commonly used for reaction blades consists of 5% Mn and 95% Cu. Where temperatures are too high, pure Ni has been used. Special alloy steels are being used for certain types. A steel containing 0.05-0.10% C, 0.30-0.50% Mn, 0.10-0.25% Si, and 4.50-5.50% Ni is used for impulse blades. Corrosion resisting steel used has 0.07-0.12% C, 0.30-0.60% Mn, max. 0.03% S and P each, max. 0.35% Si, 11.50-12.50% Cr, and max. 0.60% Ni. Forged blades are made from bars of either the corrosion-resisting or Ni steels. After forging, the blades are heated in a salt bath of No. 130 Lavite to 1750° F., quenched in circulating oil at room temperature, and drawn at 1200° F. in a salt bath of No. 110 Lavite. To eliminate scale, blades are pickled several times. Small sizes of blades are made from specially rolled shapes. MS (9)

Recent Progress on Aluminum Alloys Used in Ship Building (Neuere Fortschritte mit Aluminium-Legierungen für den Schiffbau). B. Schulz. *Korrosion und Metallschutz*, Vol. 7, Aug. 1931, pages 218-219.

The utilization of pure Al and KS-Seewasser is pointed out and the anodic treatment of Duralumin and Lautal stressed. The importance of eliminating the inclusions of gases and oxides is discussed and the results gained from some practical applications of Al-alloys on various ships are given. EF (9)

Elinvar an alloy of 53-61% Fe, 33-35% Ni, 4-5% Cr, 1-3% W, 0.5-2% Mn, 0.5-2% Si, 0.5-2% C has 3 properties which adapt it to the manufacture of watch parts, constant modulus of elasticity, resistance to magnetization, and resistance to corrosion. WLC (9)

Aluminum Cast Alloys in Aeroplane Motor Construction. (Aluminiumgusslegierungen im Flugmotorenbau.) C. Panseri. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 13, 1931, page 882.

The composition, refining, properties of light-metals and their application for the different parts of motors for aeroplanes is reviewed. Ha (9)

Commercial Vehicle Bodywork in Aluminium. *Metal Industry*, London, Vol. 39, Aug. 21, 1931, pages 180-182.

Memorandum of the British Aluminium Company, Ltd. Examples are given of the use of light metals in automotive transportation, whereby payloads can be increased and dead weight decreased. PRK (9)

Printing with Steel Sheets—Other Metals have a Rival. *Steel*, Vol. 88, Apr. 2, 1931, pages 50-53.

The new process is based on the fact that Hg rejects ink; it does not amalgamate with Fe or steel but readily with Cu and other metals. If, therefore, the areas that are not to print are covered with Cu or Ag and amalgamated these areas will not take ink while the bare steel will take it. The new process was developed in England and is said to give equal results to the collotype with the additional advantage that the surface is permanent while the collotype does not yield more than about 5000 prints. Ha (9)

Large Uses of Steel in Small Ways. 182nd article. Radio Sets. *Steel*, Vol. 88, Jan. 8, 1931, page 44.

Discusses the wide use of steel in the manufacture of parts for radio sets. JN (9)

Large Uses of Steel in Small Ways. 183rd article. Window Shade Rollers. *Steel*, Vol. 88, Jan. 22, 1931, page 42.

The roller shade industry uses 7000 tons of steel annually in the manufacture of springs and end pieces for wooden rollers and in the manufacture of all-steel metal rollers. JN (9)

Gas Cylinders. *Metallurgist*, Apr. 1931, pages 54-56.

An excellent critical comparison of the recommendations of the British Gas Cylinders Research Committee and the Swiss Federal Institution for Testing Materials regarding the mechanical testing of the material of cylinders to be used for the storage and transport of liquefiable gases. VVK (9)

Modern Blacksmithing. *Metal Progress*, Vol. 20, Dec. 1931, pages 84-88.

The author describes modern methods in making ornamental iron work. WLC (9)

Curbing and Tie Rod Design Affords Outlet for Strip. *Steel*, Vol. 88, Jan. 29, 1931, page 47.

A description of a new type of steel curbing developed for use in the resurfacing of worn out concrete pavements. A substantial saving over that of concrete curbing is claimed. JN (9)

Shipbuilding Activity Will Use 400,000 Tons of Steel. *Steel*, Vol. 88, Jan. 22, 1931, pages 15-16.

The American shipbuilding industry will require 400,000 tons of steel during the next 2 years to complete 87 steel vessels now under contract or assured—at a total cost of 300 million dollars. JN (9)

Corrosion-Resistant Steels Meet Industrial Demands. *Steel*, Vol. 88, Jan. 22, 1931, page 50.

Although the total consumption of Ni declined in 1930, the use of Ni steels and Ni products found many new outlets. The petroleum industry made increased demands for high-Ni and Cr steels, Ni-Fe alloys and pure Ni apparatus. The frozen food industry provided an entirely new outlet for Monel metal consumption. The use of Ni steels increased greatly in the manufacture of various types of heavy machinery. There was a great increase in the production of heat-resistant alloys for electrical heating elements. The successful development of an attractive and durable Cr plate on Ni promises to increase the use of Ni in plating. JN (9)

High Elastic Nickel Steel Developed for Ships. *Steel*, Vol. 89, Dec. 28, 1931, pages 28-32.

The characteristics of 6 steels are tabulated and their properties discussed. High elastic steel is used to great advantage for the strength members of the ship's skeleton; a marked saving in weight can be obtained. Ha (9)

Metals in Powdered Form are Pressed and Sintered into Various Shapes. *Steel*, Vol. 89, Nov. 16, 1931, page 40.

Powdered metals are used for automobile bearings, valve tappets, resistance bars, welding rods, tool bits, and the like. The pressures for forming powdered metals range from 6 to 125 tons/in.^{2} according to the desired density. The metals so far supplied in powdered form of from 200 to 500 mesh are Sn, Cu, Zn, Ni, Fe, steel and alloy steels; Ag, Cr, Co, Au, Pt, W, Monel metal, and Pd. Ha (9)

Large Uses of Steel in Small Ways. 184th Article. Typesetting Machines. *Steel*, Vol. 88, Feb. 5, 1931, page 52.

A brief account of the history and operation of the linotype with a partial list of parts made of steel. JN (9)

Large Uses of Steel in Small Ways. 185th Article, Folding Chairs. *Steel*, Vol. 88, Feb. 19, 1931, page 42.

About 300 tons of steel are consumed annually in the manufacture of folding steel chairs. These find a widening market in schools, hotels, offices, hospitals, clubs, apartment houses and even private homes. The features of folding steel chair construction are described briefly. JN (9)

Steel Floor is Built Up of Rolled Structural Shapes. *Steel*, Vol. 89, Nov. 8, 1931, pages 34-36.

The method of construction is described; advantages are said to be elimination of buckling, warping, and bending, and uniform distribution of wind stresses to all building columns. A load of 120 lbs./ft.^{2} can be borne on a 7-foot span. Ha (9)

Develops Cast Iron Roofing for Industrial Buildings. *Steel*, Vol. 89, July 30, 1931, pages 38-39.

The method of laying cast-iron plates on sloping roofs is described and illustrated; this kind of roof resists atmospheric corrosion well. Ha (9)

Forges Exhaust Valve of Alloy Steel with Copper Cores for Cooling. *Steel*, Vol. 89, Sept. 10, 1931, page 42.

Describes a valve for explosion motors. Ha (9)

Gasoline Stations made of Steel. (Tankdienst-Stationen aus Stahl.) *Petroleum*, Vol. 27, Sept. 16, 1931, pages 1-4; Dec. 23, 1931, pages 958-960.

The utilization of steel for the construction of gasoline service stations is shown and 14 advantages for this special usage of steel are pointed out. EF (9)

Tool Steel Analyses and Applications. W. H. WILLS. *Steel,* Vol. 88, June 25, 1931, pages 31-32, 38; Vol. 89, July 9, 1931, pages 33-38.

A classification is given of tool steels and their properties and the fields of specific application are described. Ha (9)

Uses and applications of aluminum paint and foil. VVK (9)

Molding in Metals. J. HOMER WINKLER. *Brass World,* Vol. 28, Jan. 1932, page 7.

Four methods of producing electrotypes are: Pb molding, electrodeposition, fusible alloy and the galvanotex process. Each process is outlined. WHB (9)

Stresses in Railroad Track. S. TIMOSHENKO & B. F. LANGER (University of Michigan and Westinghouse Research Laboratories). *Advance copy, American Society of Mechanical Engineers,* Nov. 30, 1931 Meeting, 17 pages.

The general problem is discussed and methods of measurement of the stresses described. It is concluded that in a 130-lb. rail, the fillet under the head due to an eccentrically applied vertical load plus a high lateral flange pressure may have a stress range of 70,000 lbs./in.^{2}, from 60,000 in compression to 10,000 in tension, while the head itself, under vertical and lateral load may have a stress range of 75,000 lbs./in.^{2}, from 60,000 in compression to 15,000 in tension. Such repeated stresses are rather close to the endurance limit of ordinary rail steel; slight defects in the material could readily cause failure. It is unlikely that rail stresses start cracks in sound material, but they may do so in the presence of internal shatter cracks. Freeman's suggestions as to causes and possible methods of prevention of shatter cracks are cited. The studies indicate that the maximum bending stress, with similar rail sections, remains constant if the weight of the rail is increased in direct proportion to the load, thus justifying the use of heavier rails as rolling stock becomes heavier. A more uniform stress distribution would result if the web were thickened at the upper part at the expense of the lower part. By such redesign of a 130-lb. rail, the stress at the upper web fillet, which is one of the most highly stressed locations, can be reduced some 20%. The contact stress in the rail head is very localized and very high; it produces mostly plastic flow in the head. HWG (9)

Light Aluminum for Overhead Traveling Cranes. R. L. TEMPLIN. *Engineering News Record,* Vol. 107, Oct. 8, 1931, pages 574-576.

The considerations which should be leading for the use of aluminum in the place of steel for cranes are discussed and formulas for the calculation are given. At present, 15 cranes of this kind of from 10 to 50 tons capacity are in operation at the works of the Aluminum Co. of America. The weight saved by the use of aluminum varies from 26 to 61%. Details of construction are described. Ha (9)

Material for Highly-Stressed Boilers During the Last Decade. Precautions against Tube Failures. (Die Werkstoffe für Hochleistungsdampfkessel im letzten Jahrzehnt. Vorbeugungsmassregeln gegen Rohrmängel.) M. ULRICH. *Die Wärme,* Vol. 54, July 4, 1931, pages 528-534.

Due to the increase in boiler pressures to 120 atmospheres and above, and owing to the rise of super-heating temperatures to about 500° C., the material is stressed to such a degree as to urgently demand fundamental changes with respect to the construction, improved methods of manufacture, development of novel boiler elements and manufacture of high quality material. After making some general statements on carbon and alloyed steels, steel castings, cast iron and on complete boiler parts, Ulrich (See also *Metals & Alloys,* Vol. 2, 1931, page 34) focusses attention on the prevention of defective tubes, going back as far as to the steel ingot. The writer separately treats the individual stress and special material in regard to (a) water tubes, (b) super-heater tubes, (c) preheater units, (d) boiler drums, (e) smaller supplementary parts, forged and cast steel parts, (f) screws and nuts, (g) steam pipe lines. EF (9)

Getting the Most Out of Die Castings. L. H. MORIN. *Metal Industry,* London, Vol. 39, Aug. 28, 1931, pages 197-198.

From *Iron Age,* Aug. 6, 1931. Die casting of odd shapes and of integral dowel pins and so forth saves time in assembling and is cheaper than machining. Illustrations of practical applications are given. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 40. PRK (9)

Utilization of Silver for Chemical Apparatus. (Die Verwendung von Silber in der chemischen Apparatur.) D. MACDONALD. *Die Metallbörse,* Vol. 21, Apr. 8, 1931, pages 653-654.

Due to the low silver price, increasing tendencies are noticed which aim at a wider adoption of silver as a construction material in the fields of chemistry. The favorable properties of this "rare" metal and the commercial utilization up to the present time are discussed. EF (9)

White Metal Antifriction Alloys. F. C. THOMPSON. *Tin,* Dec. 1931, pages 4-6.

In a general discussion of bearing metals the lack of exact knowledge of the properties desired in a bearing metal and the relations to the lubricant is commented upon. In general, Sn-base alloys are preferable to Pb-base alloys. The old practice of hammering the bearing metal surface is strongly deprecated, as it softens the metal and, particularly, breaks up the hard and brittle cubes, with the result that the shaft is scored by the teeth-like particles. Further, in remelting white metals prior to recasting, considerable care should be taken, as Sn readily oxidizes and the Sn oxide so produced is admixed with the metal in the form of very hard, sharp fragments. The use of powdered charcoal or a suitable flux will prevent this, and a better bearing will result. Ha (9)

Exchangeable Cylinder Bushings (Auswechselbare Zylinderlaufbüchsen). E. MAHLE. *Deutsche Motorzeitschrift,* Vol. 8, May 1931, pages 166-180.

Covers wear, hardness tests, manufacture, material, dry vs. lubricated cylinder bushings, advantages of exchangeable bushings, scope of utilization. EF(9)

Material for Boiler Construction. (Werkstoffrage im Dampfkesselbau.) F. NEHL. *Die Wärme,* Vol. 54, Apr. 25, 1931, pages 295-299. Sonderheft "Werkstoff und Herstellung im neuzeitlichen Dampfkesselbau."

The paper which was presented before the Zentralverband des Preussischen Dampfkessel Ueberwachungsvereins, 1931, discusses the sources of failure in service and reports on means of overcoming the difficulties. Seamless and welded high-pressure drums are considered and the manufacture of seamless drums according to the manufacturing method of Roeckner is described. The significance of the yield point at elevated temperatures and of the creep resistance with reference to the calculation of the wall-thickness of drums and tubes is dealt with. The commercial boiler materials exhibiting remarkable physical properties at elevated temperatures are given and their resistance towards scaling is emphasized. Most of the information is clearly arranged in 13 illustrations, diagrams and 3 tables. EF (9)

Seamless Chrome-Nickel Steel Tubes find Diversified Uses. H. D. NEWELL. *Steel,* Vol. 88, Mar. 19, 1931, pages 31-33, 52.

A list of applications, especially in boiler construction, is given and the physical properties of Nirosta KA2-tubes are described. Ha (9)

Metal Foil Applications. R. P. STRANAHAN (Reynolds Metals Co.). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 206-208.

The author describes the application of the use of foils for various purposes, mainly in food packages. WLC (9)

Dental Casting Technic: Theory and Practice. GEORGE C. PAFFENBARGER & W. T. SWEENEY. *Journal of Dental Research,* Vol. II, Oct. 1931, pages 681-701.

A report to the Research Commission of the American Dental Association on work done at the National Bureau of Standards. The relations of the properties of materials used in the production of dental castings to dimensions of the castings were studied. The important materials are the inlay wax, the investment, and the gold alloy. Since all gold alloys show a casting shrinkage, compensation was sought by expanding the wax pattern or the investment, or both. The preparations were made in steel cylinders and the shrinkage noted by fitting the castings into the cavities. It was found that the kind of wax, its expansion or contraction before being invested, the kind of investment (silica, plaster, etc.), the ratio of powder to water, the temperature of the mold, and the temperature of the molten gold are important factors. Castings are shown which correlate physical data and actual results. Castings made in cristobalite (75% cristobalite, 25% plaster) investment at temperatures from 400° to 800° C. gave accurate restorations. The composition of the gold alloy is not given. 17 figures and 8 references. OEH (9)

The Relation of Torque to Tension for Thread-Locking Devices. H. L. WHITTEMORE, G. W. NUSBAUM & E. O. SEAQUIST. *Bureau of Standards Journal of Research,* Vol. 7, Nov. 1931, pages 945-1016.

This investigation was made to determine, under static loads, the torsional resistance to unscrewing the nuts, with and without locking devices and the relationships these torques bear to the stresses in the bolt. The torque required to produce a given stress in the bolt was also determined for each device. 24 manufacturers of thread-locking devices accepted the invitation to submit samples of their device for test and agreed to publication of the results. A total of 41 devices were tested, including such devices as standard nuts, jam nuts and slotted nuts with cotter pins. Only about one-quarter of these devices showed any appreciable difference in the static torque-tension relation from that of the American National coarse-thread standard nut. There was no great difference between the torques for regular nuts with jam nuts and the torques for regular nuts without jam nuts. The torques for slotted and castellated regular nuts with cotter pins were greater than those for regular nuts after the nut had been screwed off sufficiently to develop the shearing resistance of the cotter pin. Unless the cotter pin was a snug fit in the slot, however, the screwing-off torque never exceeded the initial value, because the shearing resistance of the cotter pin was low and the stress in the bolt decreased as the nut was unscrewed. All of the spring and lock washers roughened the bearing surface and the face of the nut. After closing flat they were all permanently deformed. As the nut was screwed off, the torques were at first about the same as those for regular nuts. When the washer had rotated sufficiently for the ends of the washer to cut into the surfaces and offer considerable resistance to rotation, the stress in the bolt had, for many of the spring washers, been reduced to a low value. WAT (9)

Magnesium Alloys in the Aircraft-Engine Construction. G. D. WELTY. *S. A. E. Preprint,* 1931, 9 pages; *S. A. E. Journal,* Vol. 30, Mar. 1932, pages 112-115.

The substitution of Mg base alloys for those of Al is discussed, and the physical properties of Mg and Al castings and forgings are compared. Features of design which should receive special attention when changing from an Al casting or forging to the same part in Mg are emphasized. The most promising immediate field for the Mg alloy is said to lie in those applications where strength and lightness are the main considerations and where high temperature properties are of secondary importance. Machining practice for Mg alloys is covered in some detail as well as the question of protection against corrosion. It is stated that the present casting alloys have proved commercially satisfactory, from the corrosion standpoint, for all types of land service and for most salt water service, in the middle and upper latitudes. In tropical salt water, however, a certain amount of trouble has been encountered and some protective measures appear necessary. A few recent developments in fabricating the Mg alloys are included. Ha+WAT (9)

Ship Builders Seek Non-Rusting High Strength Steels. W. J. PRIESTLEY. *Steel,* Vol. 89, Nov. 30, 1931, pages 33-34.

The newer alloy steels permit a decrease in dead weight of ships without sacrifice of high strength. A table of various structural steels with the desirable characteristics is given; none of these steels has less than 90,000 lbs./in.^{2} ultimate strength with a yield point of from 50 to 90,000 lbs. and a carbon content of 0.3 to 0.4%. Ha (9)

Steel Construction of a Storage House. (Ein Lagerhaus in Stahlkonstruktion.) J. Gollnow. *Montanistische Rundschau, Stahlbautechnik,* Vol. 23, Feb. 16, 1931, pages 9-12.

The steel frame of an 8 story building and assembling is given. EF (9)

Special Quality Steels for Shipbuilding. William Bennett. *Iron & Coal Trades Review,* Vol. 123, Dec. 4, 1931, page 863; *Marine Age,* Vol. 5, Nov. 20, 1931, pages 12-13, 28.

Recent developments are reviewed and the new materials compared with some of other large ships built previously. The mechanical properties of structural Si steels, high-tensile Ni steel and high-tensile castings are given and a few recent examples of modern ships briefly described. Ha (9)

The Manufacture and Use of Steel Railway Sleepers. R. Carpmael. *Engineering,* Vol. 152, Dec. 18, 1931, pages 644-647; Dec. 25, 1931, pages 671-673.

Includes discussion. From paper read before the Institution of Mechanical Engineers. See also editorial commenting on this paper on pages 653-654 of the Dec. 18, 1931, issue. LFM (9)

Steel Railway Sleepers. R. Carpmael. *Iron & Coal Trades Review,* Vol. 123, Dec. 18, 1931, pages 944-945.

The general manufacturing requirements, specifications of materials used, inspection and gaging are discussed and continental and British practice compared. Ha (9)

Developments in Marine Engineering Foundrywork. Summers Hunter, Jr. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 33-34.

An article, accompanied by 2 tables and 1 photograph. The progress which has been made in motor-driven ships is referred to and improvements in Diesel engine design and practice are discussed. The fact that so many important parts of Diesel engines are manufactured of cast iron is referred to, and the value of high-duty cast irons in this connection is dealt with. OWE (9)

Wire Rope for Oil Well Pumping. Percy R. Clark. *Wire & Wire Products,* Vol. 7, Jan. 1932, pages 12-15, 33-34.

The advantages of wire rope in oil well pumping are pointed out and results of an investigation made in the oil fields of Rumania cited where economies up to 50% could be obtained. Ha (9)

Steel-Frame Residences Find Favor in France. Vincent Delport. *Steel,* Vol. 88, Jan. 15, 1931, pages 35-37, 42.

A résumé of the principle features of construction and assembly of 5 different types of steel houses erected in France during the past 3 years. JN (9)

Flying Would Be Impossible Without Metals. G. E. Everett. *Metal Industry,* N. Y., Vol. 29, Nov. 1931, pages 481-482.

A general description is given of non-ferrous metals vital to airplane construction, beacon lights, and radio communication, and other essential departments of the flying industry. PRK (9)

Chromium-Molybdenum Steels and Their Use in Aviation (Les aciers au chrome-molybdene et leur emploi dans l'aviation). M. Baer. *Revue de Métallurgie,* Vol. 28, Oct. 1931, pages 570-574.

Cr-Mo steels originated in the United States, but at present are widely used in France for aviation purposes. French analyses include, however, besides 0.30% Mo and 0.75-1.30% Cr, from 1.5-4.0% Ni. Tubing made of it averages, after heat treatment, a minimum tensile strength of 70 kigs./mm.^{2} and 12% elongation. Being air hardening, the material furnishes superior material for aeronautical welding constructions. In case of thin walled tubes, the deposited metal is 50 to 100% thicker than the tube walls, so that no special welding rod is required. Several types of tube welded joints particularly suitable for airplane construction are given. JDG (9)

The Metal-Clad Airship. Carl B. Fritsche. *Journal Royal Aeronautical Society,* Vol. 36, Sept. 1931, pages 818-883.

Brief historical notes on the development of the airship serve as introduction to a complete description of the first successful metal-clad airship, the ZMC-2. The author follows this description with a thorough analysis of the problems of design, construction and operation of this type of aircraft. WHB (9)

Data on Boiler Materials (Berechnungswerte der Kesselbaustoffe). Fr. P. Fischer. *Krupp'sche Monatshefte,* Vol. 12, Oct. 1931, pages 267-271.

New results of investigations made it necessary to revise the previous tables on hot yield point and hot tensile strength of boiler materials, as given by Fr. P. Fischer & V. Ehmcke in *Krupp'sche Monatshefte,* Vol. 10, Dec. 1929, pages 209-211 and abstracted in *Metals & Alloys,* Vol. 1, May 1930, page 521. The 3 new tables give data at elevated temperatures on common boiler steels group I-IV and Izett-steels, on the same steels in forged state and on Ni-bearing boiler steels. GN (9)

Problems Involved in the Choice and Use of Materials in Airplane Construction. P. Brenner. *Technical Memorandum* No. 658, *National Advisory Committee for Aeronautics,* 25 pages. Mimeographed.

This is a translation of an article in *Zeitschrift für Flugtechnik und Motorluftschiffahrt,* Nov. 14, 1931, pages 637-648. Comparison of wood, light alloys, and steels. Duralumin and elektron have no actual fatigue limit, while the steels do. On the basis of 100 million cycles, steel, heat-treated to 230,000 lbs./in.^{2} tensile (such as Cr Ni W) has the highest endurance limit per unit weight, elektron is next, and far behind come carbon steels and duralumin. Notched endurance specimens of elektron, however, show up better than steel, according to Ludwik's tests. Wood is also useful for parts subject to vibration. Corrosion of duralumin is discussed, with the usual conclusions that for service under marine conditions it is necessary to use duplex sheet coated with pure Al or a copper-free Al, or else anodic treatment followed by painting or greasing. An alloy "hydronalium" containing 7% Mg, ½% Mn, which, hard rolled, has properties approaching those of heat-treated duralumin, has good corrosion resistance and is promising for floats and hulls. Elektron has too low corrosion resistance for use on seaplanes, but has some use in land planes. Rust proof Cr steel seems so far to be the best solution of the seaplane corrosion problem. HWG (9)

The Selective Application of Castings. R. A. Bull. *Steel Founder,* Vol. 2, Jan.-Feb. 1932, pages 24-28.

The factors governing the use of castings, forgings or welded structures are discussed; steel castings have been extensively used in recent times. The importance of proper design in each case and of research work, particularly as to the causes of failures, is pointed out. Ha (9)

Bearing Metals. C. H. Bierbaum. *Conference on Metals & Alloys, Case School of Applied Science,* Cleveland, Ohio, Paper No. 17, Nov. 1932, Mimeographed. 4 pages.

The importance of a duplex structure, with hard particles that stand in slight relief after the bearing has been worn in, is stressed. The hard particles should not be distinctly abrasive to the journal. While the bearing should be heterogeneous, the journal should be homogeneous. Soft journals will not stand up against bearings with very hard particles. Accelerated laboratory bearing tests are described and study of satisfactory and unsatisfactory used bearings advocated. HWG + Ha (9)

How Much Power Should Gears Transmit? Earle Buckingham (Massachusetts Institute of Technology). *Machinery,* Vol. 38, Oct. 1931, pages 81-87.

Allowable load-transmitting capacity of gears may be considered as to: (1) static tooth load; (2) load capacity when intermeshing so that impact stresses must be considered; (3) load capacity as limited by tooth wear. Excessive pressure will cause surface failure and pitting due to compressive fatigue. Includes formula for determination of allowable load and several tables of strength of gears of different pitch, tooth form and metal. Metals included are cast iron, semi-steel and bronze, cast steel, SAE 1030 steel, SAE 1045 steel, SAE 3245 steel and others of various forms of hardened steel. RHP (9)

Pots 'n' Pans. *Metal Progress,* Vol. 18, 1930, pages 38-41.

Description of applications of Monel, pure nickel, and stainless steels in the Harvey Restaurants in the Cleveland Union Terminal. WLC (9)

British Coinage. *Journal Society Chemical Industry,* Vol. 49, Jan. 3, 1930, page 15.

Brief note on composition of new English silver coinage (Ag, 50%; Cu, 40%; Ni, 5%; Zn, 5%). VVK (9)

Oxy-Acetylene Welded Aluminum Products. *Industrial Gases,* Vol. 12, Mar. 1931, pages 24-30.

Fields for Al and its alloys are broadened by more extensive use of the oxy-acetylene process. Describes new applications of ox weld, e.g., motor truck bodies, decorative furniture, pipe fittings, door frames, "dry ice" containers and roofing. Also gives technique and general rules for welding Al and alloys. DTR (9)

Welding Procedure for Saw Repairing. *Industrial Gases,* Vol. 12, 1931, pages 43-45.

Gives 3 processes and their uses for saw welding. (1) Electric butt or flash welding machine; (2) atomic hydrogen welding torch; (3) oxy-acetylene or gas welding torch. In the future large mills will repair broken and cracked saws by welding. DTR (9)

Aluminum Cans. *Journal Society of Chemical Industry,* Vol. 50, Apr. 17, 1931, page 324.

The increased use of aluminum for the preservation of foodstuffs by the canning and allied industries has led to the standardization of sheets suitable for the purpose. These are supplied in boxes of uniform weight of 112 lbs., in which the number of sheets varies with the size and thickness. In the following abbreviated table the thickness and size of the aluminum sheets is given, together with the number of sheets to the hundredweight; there is also an indication of the gage and designation of the corresponding tinplate:,

Thickness in.	Tinplate gage and designation	Size	Approximate No. of sheets per cwt.
0.0124	29.9 IC	20x14	330
0.0156	28 IX	28x20	130
0.0179	26.8 IXX	30x21	99
0.0201	25.8 SDK	22x15	174
0.0225	24.8 XXXX	20x14	182
0.0375	20.4 DXXXXXX	34x25	35

It is pointed out that the number of sheets varies slightly and the thickness is subject to the usual commercial rolling tolerances of ± 2%. If desired, thinner sheets may be obtained, but the makers do not encourage this because of the softness of the metal, except in cases of very small containers that do not call for very much working. (9)

Chromium Plating's Largest Field is Industrial. *Metal Industry,* N. Y., Vol. 29, Oct. 1931, pages 430-432.

A list of the properties and industrial uses to which Cr plate has been put is given by the Vacuum Can Company. PRK (9)

Powdered Metals Open New Field in Alloy Applications. *American Metal Market,* Vol. 38, Aug. 29, 1931, page 5.

Originally printed in the bulletin of International Nickel Co. Points out the modern trend of using powdered metals, either as fine as talcum or as coarse as granulated sugar. Used in making paints, inks, welding wires, various alloys and bearings for automobiles and electrical equipment, which never have to be oiled. They may also be sprayed on metals as well as mixed with or sprayed on plastic materials. Powdered Ni, Cu and Sn make possible production of porous metal bearings capable of holding 4-6% of their own weight of liquids. Charles Hardy of New York has been in the forefront of powdered metal development. DTR (9)

Twist Drills, Proving Their Quality. *Metal Progress,* Vol. 20, Oct. 1931, pages 48-53.

Studies at Morse Twist Drill and Machine Co., New Bedford, Mass., in development of better twist drills and methods for controlling their quality are discussed. WLC (9)

Lead Fittings for Modern Dwellings. *Metal Industry,* N. Y., Vol. 29, Sept. 1931, page 396.

Illustrates the use of Pb around homes. PRK (9)

Steels for Aircraft Engines 1918 vs. 1930. *Metal Progress,* Vol. 19, Jan. 1931, pages 70-76.

Substitution of aluminum alloy parts for cast iron and use of lighter sections of heat-treated steels has greatly reduced the weight:horsepower ratio of internal combustion engines. Discussion of steels and their applications. WLC (9)

Manufacture of Springs from Hardened Low-Carbon Steel. (Ueber die Herstellung von Federn aus gehärtetem weichen Flussstahl.) H. Wiesecke. Doctor's thesis, Technische Hochschule Aachen, 1931. Paper, 6 x 9 inches, 81 pages.

Basic Bessemer and basic open-hearth steel of .04 to .12% C was hot rolled to about 6 mm. diameter, water quenched and drawn down to about 3.6 mm. diameter. In a commercial-scale test, material of 0.06% C, rolled to 6 mm. diameter, and cooled normally on the hot bed, gave 66,000 lbs./in.^{2} tensile, 33% elongation. After quenching by immersing the 120 lb. coils in cold circulating water (providing the quenching temperature was high enough, i. e., if the rods were not too cold and the time in rolling not too long), the tensile strength rose to 87,000-105,000 lbs./in.^{2} averaging 94,000, with about 17% elongation. On drawing down to 3.6 mm. wire, the tensile strength rose to 142,000-172,000 lbs./in.^{2} Such wire was reported by spring makers as satisfactory for coiled springs.

A previous large scale test was unsuccessful because it was run on Monday morning, with the rolls, reels, etc. too cold so that the quenching temperature was below 910° C. The quenching water must not be allowed to warm up.

The conclusion is drawn that very great attention must be paid to the control of the process, else segregation in the ingot, differences in quenching temperature, in water temperature, etc., will prevent getting the desired properties uniformly.

The quenching method is only applicable to relatively small diameter wire, and to small coils, but the cheapness of the starting material as compared to higher carbon steel, within the limits in which it is applicable, makes it promising for use by plants having available cheaply the large amounts of water necessary for quenching, and willing to exercise the close control required. Basic Bessemer steel is preferred, though open-hearth is usable.

Properties are plotted of several low carbon steels subjected to many tests in the laboratory, and the metallography of the structures obtained is discussed in some detail.
H. W. Gillett (9)-B-

Metals and Alloys in Modern Building. G. Magulo. *Conference on Metals and Alloys, Case School of Applied Science,* Cleveland, Ohio, Paper No. 13, 1931, 2 pages. Mimeographed.

Brief comment on applicability of various metals to modern architecture, both for decorative use and as structural parts. Ability to preform parts in the factory and erect them speedily on the job is a factor. HWG + Ha (9)

Trucks with Aluminum Tanks. (Grosstankwagen aus Aluminium). *Petroleum,* Vol. 27, June 24, 1931, pages 4-5.

Illustrations and description of aluminum tanks with a gasoline capacity of 2400 gals. built by the Standard Steel Works, Kansas City, Mo., and with a capacity of 10,000 liters built by the Daimler-Benz A. G., Gaggenau, Baden. EF (9)

Something on the Possibilities for Use of Beryllium Alloys for Tools (Etwas über die Verwendungsmöglichkeiten von Beryllium-Legierungen im Werkzeugbau). *Das Werkzeug, (supplement to Maschinenkonstrukteur-Betriebstechnik),* Vol. 7, June 10, 1931, page 124.

Be is of use particularly for pressing and stamping tools because of its light weight, corrosion-resistance, and high elasticity. Its chief range of usefulness lies in the alloying with 20% Cu, Ni or Fe. Beryllium bronzes have a relatively high tensile strength and high elongation. They are the alloys of Be whose production is of practical value. MAB (9)

Light Metal Alloy Pistons for Combustion Engines. (Kolben für Verbrennungskraftmaschinen aus Leichtmetallegierungen.) W. Schulze. *Dinglers Polytechnisches Journal,* Vol. 346, Dec. 1931, pages 193-195.

Statistic data are presented showing the substitution of light metal alloy pistons for cast-iron pistons since 1926, and the technological reasons therefor are summarized. The writer then takes up the various construction devices which must be borne in mind when designing light metal pistons. The different materials available and their physical properties with reference to their chemical composition are considered and the paper concludes with a discussion of the various kinds of testing to which the materials employed are submitted. EF (9)

Special Copper-Bearing Alloys as Recent Commercial Materials (Sonderlegierungen aus Kupfer als moderne technische Werkstoffe). W. Schulze. *Dinglers Polytechnisches Journal,* Vol. 346, Oct. 1931, pages 164-167.

Attention is focussed upon Monel metal, artificial Monel metal and other Ni-Cu alloys, Ni-bearing brasses and bronzes, German silver, brass and bronze containing additions of Al, Cu-Al alloys. Chemical analysis, physical and chemical properties, commercial utilization, etc., are dealt with. EF (9)

Alloys in Aircraft Engines. R. R. Moore. *Conference on Metals and Alloys, Case School of Applied Science,* Cleveland, Ohio, Paper No. 18, Nov. 1931, 6 pages. Mimeographed.

Growing Use of Chromium Plating in the Rubber Industry. N. Hal McKay. *Rubber Age,* Vol. 29, Sept. 25, 1931, pages 554-556.

Great economies due to high resistance to wear and corrosion were effected by the use of chromium plating of mill rolls, tuber screws, molds, mandrels and other equipment necessary to the manufacture of rubber. Ha (9)

The Development of the Werdau Light Metal Coach Construction (Die Entwicklung des Werdauer Leichtmetall-Omnibus-Aufbaues). Lindemann. *Verkehrstechnik,* No. 4, 1931, pages 180-181.

Description of the 3 axle chassis for 48 seats. The saving in weight over the same construction in steel is 27%, although the same properties are present as would have been the case with steel. Ha (9)

Economy of Steel Ties is Proved at Scarbro Mine. A. R. Long. *Coal Age,* Vol. 36, Sept. 1931, pages 483-484.

A tabulation covering 3 years shows a total saving of almost $18,000 over wood ties. Ha (9)

Silumin in Mining and Crude Oil Production. (Silumin im Bergbau und in der Rohölgewinnung.) E. Lohrke. *Petroleum,* Vol. 27, Dec. 1931, pages 955-958; *Montanistische Rundschau,* Vol. 23, Oct. 16, 1931, pages 276-278.

A table collecting 15 different physical properties of 5 commercial light metals and light metal alloys is given and the actual utilization of Silumin in mining industries is demonstrated by several examples. EF (9)

Pacific Coast Harbors Open Market for Steel Piling. Kaye Baron Lansdowne. *Steel,* Vol. 88, Feb. 5, 1931, pages 48-50.

The growing popularity of the Dietz method of open sea harbor construction on the West Coast as a trade asset to cities lacking in natural harbor facilities and the northern spread of the marine borer which attacks wooden piling, are both contributing to the development of a large present and future market for American steel piling in competition with German steels. JN (9)

Metallurgical Chemistry in the Aeronautical Industry (La chimica metallurgica nell' industria aeronautica). Adelaide Labo. *Rivista Aeronautica,* Vol. 7, July 1931, pages 30-44.

Light metals used for the construction of different parts of the airplane are reviewed and their physical and chemical properties are outlined in functions of their heat treatment. The chemical compositions of the special steels used by the American aviation industry are listed in tables and reference is made to types of steel employed in fuselage construction. Aluminum alloys are considered with emphasis on their increasing importance and the composition of duralumin, superduralumin, cast aluminum, alpax, lautal, avional and antierodal is discussed. The article concludes with references to the advantages of different forms of Mg alloys and their mechanical properties, as well as the possibilities of Be alloys. WAT (9)

Light Metal Alloys for Materials of Construction in the Machine Industry (Leichtmetallegierungen als Baustoffe in der Maschinenindustrie). M. Koenig. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 561-573. 3 figures, 18 references.

Composition and properties of 10 Al alloys, electron, medium carbon steel and Ni Cr steel are compared. Welding and protection against corrosion are discussed. No new data are included in the résumé. HWG (9)

Higher Priced Materials without Added Costs. LeRoy H. Labaw. *Product Engineering,* Vol. 2, Oct. 1931, pages 446-448.

By making full use of the die-casting properties and by designing to save machining and assembly costs, complicated parts were made for cylinder heads, pump yokes, etc. Ha (9)

Stainless Steels. M. J. R. Morris. *Conference on Metals and Alloys, Case School of Applied Science,* Cleveland, Ohio, Paper No. 2, Nov. 1931, 5 pages. Mimeographed.

Flat sheet metals are coming into architectural use. The Empire State Building was erected in 60 days' less time because of the use of sheet. The main fields for stainless alloys are in exterior architectural use, in resistance to dry corrosion (scaling at high temperature) and in resistance to wet corrosion. Very brief comment is given on types of alloys, treatment and uses. HWG + Ha (9)

Practical Advice Concerning the Building of Monel Metal Dye Tanks (Praktische Ratschläge zur Konstruktion von Färbetanks aus Monell-Metall-Blech). R. Mueller. *Melliand Textilberichte,* Vol. 12, Jan. 1931, pages 73-76.

Anticipating the special requirements to be met with in tanks of the dyeing industry, the author takes up fully the following problems: (1) strength of the solders and their corrosion resistance; (2) folded joints; (3) welded joints, (a) oxy-acetylene welding, (b) electric arc welding; (4) flanging and riveting. EF (9)

Reinforcing Main-Line Railway Bridge by Welding. A. M. Knowles. *Engineering News Record,* Vol. 107, Sept. 10, 1931, pages 411-412.

The method of increasing the section of each flange by 36 in.^{2} and 22 in.^{2}, respectively, in order to keep within safe limits of stress is described in detail; 63,000 lbs. of metal was added; 2460 lbs. of welding wire was employed. Ha (9)

High-Pressure Pipe Lines. J. Kloepper & J. Wasser. *Engineering Progress,* Vol. 12, June 1931, pages 121-127.

The making and laying of gas lines for 115 lbs./in.^{2} and water lines of 2¼ to 3 ins. wall thickness is treated in detail. The pipes are water-gas or fusion-welded with lap welds. Several examples are illustrated. Ha (9)

Alloys in Machine Tools. D. M. Gurney. *Conference on Metals & Alloys, Case School of Applied Science,* Cleveland, Ohio, Nov. 1931, Paper No. 15, 7 pages. Mimeographed. *Metal Progress,* Vol. 21, Jan. 1932, pages 46-51.

The machine tools used in working metals, including lathes, planers, shapers, milling machines, drills and grinders are discussed. The development from ordinary steel to high-speed steel and the advent of electric drive and its influence on the construction are described at length. 3½% Ni steel, low Cr-Ni steels and medium Cr-Ni steels are used in great quantities, in the production of gears, high-duty shafts and carburized parts. As an example of the various materials, the design of a turret lathe is described with its ferrous and non-ferrous alloys for the different places. The composition of several standard alloys is given.

Describes the new all-steel and glass office building of the Worcester Pressed Steel Co. at Worcester, Mass. JN (9)

HEAT TREATMENT (10)

Case Hardening & Nitrogen Hardening (10c)

Carburizing With Gas in an Electric Furnace. H. E. Koch. *S.A.E. Journal*, Vol. 29, Nov. 1931, pages 369-371.

Nitriding sometimes demands a furnace which cannot be kept employed all the time. It also stimulates the development of carburizing processes. A furnace is described which can be used for both nitriding with ammonia and carburizing with either city gas or gas produced by vaporizing a specially blended compound. Carburizing costs by this method and by the electric box-furnace method are tabulated for comparison. Relatively low first cost and operating cost and a high degree of flexibility are claimed for the equipment. Discussion has to do with difficulties with alloys in high temperature equipment, the effect of the diffusion treatment, methods of packing work to secure uniform treatment, and protection of local surfaces which should not be case-hardened. WAT (10c)

Gears for Aircraft Engines a Quality Product. A. K. Hamer. *Steel*, Vol. 89, Aug. 6, 1931, pages 41-42, 95.

The reasons for spalling of gear teeth of carburized steel are discussed and a Cr-V steel and its proper treatment described for a high quality product. Micrographs to show the fine structure are reproduced. Ha (10c)

An Appraisal of Nitriding. M. A. Grossmann. *Engineering*, Vol. 131, June 19, 1931, page 802.

Paper read before the American Iron & Steel Institute, New York, May 1931. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 246. LFM (10c)

What is Nitriding? How is it Done? J. H. Cates. *Machinery*, Vol. 37, Mar. 1931, pages 489-493.

A general discussion and explanation of the principle and methods and apparatus involved in carrying out this process. Ha (10c)

Nitriding of Alloyed Steels. W. J. Merten. *Heat Treating & Forging*, Vol. 17, Jan. 1931, pages 27-30.

The process of nitriding depends on 3 reactions: (1) decomposition of ammonia (NH_3) into nascent N and free H gas; (2) interaction of nascent N with metallic elements to form complex nitride $Mo_3N_2Fe_2N$ and $Cr_2Fe_2N+Fe_2N$ (depending on composition of alloy steel); (3) diffusion of the nitride through the matrix, forming solid solution with Fe at the temperature of the processing cycle. Maximum solubility is reached at 1100° F. The decomposition of NH_3 takes place at a temperature of approximately 800° F. An equipment of nitriding furnaces is described. Ha (10c)

How to Obtain Best Results in Nitriding. J. H. Cates, Jr. *Machinery*, Vol. 37, June 1931, pages 742-743.

The preparation of the work to be nitrided, the composition of the steels suitable for nitriding, protecting surfaces that are to be left soft are generally discussed. Ha (10c)

Recent Experiences with Nitriding Steel, Especially in Construction of Machine Tools. (Neuere Erfahrungen mit Nitrierstahl, insbesondere im Werkzeugmaschinenbau.) W. Haufe & F. Bruehl. *Krupp'sche Monatshefte*, Vol. 12, Nov. 1931, pages 295-299.

A few tests are described for determining if any changes in accuracy of assembly, deformation, hardness could be detected with nitriding steel after different times of operation. Nitrided gears for instance showed after 10,000 hours of service no trace of wear. 8 references. Ha (10c)

Nitriding Containers. J. W. Harsch & J. Muller (Leeds & Northrup Co.). *Metal Progress*, Vol. 20, Dec. 1931, pages 41-44.

A parasitic reaction by which containers for nitriding rob the atmosphere of NH_3 available for nitriding the charge has been observed with certain container materials, notably 18-8. As the containers are used, poorer nitriding results are obtained in the charge and heavy nitriding of the container takes place. High nickel alloys (Ni over 60%) and inert nonmetallic materials (fused silica, etc.) were found very resistant to nitriding. Mn content in the nickel alloys above 0.50% results in rapid attack of the container material. Enamel coatings are commented upon but their expansion characteristics and mechanical properties offer difficulties. Of the alloys, one of 62% Ni and 12.5% Cr is best suited; 18-8 is poorest. All metals are more or less affected and welding affects their resistance. A semi-refractory insulating brick container backed by welded metal container to be gas tight offers the best solution of the problem. WLC (10c)

Hardness and Crystal Structure of Nitrided Steels Linked. O. E. Harder & Geo. B. Todd. *Steel*, Vol. 88, Mar. 19, 1931, pages 51-52.

Investigations of the correlation of hardness and crystal structure of nitrided steels at different depths suggest the desirability of developing nitrided cases consisting entirely of the α-Fe phase; it was found that cases showing the face-centered cubic and α-Fe lattice were not brittle; methods should therefore be developed which produce nitrided cases free from the hexagonal lattice phase. Ha (10c)

Correlation of the Crystal Structures and Hardness of Nitrided Cases. O. E. Harder & G. B. Todd. *Transactions American Society for Steel Treating*, Vol. 19, Nov. 1931, pages 41-65.

See abstract of preprint, *Metals & Alloys*, Vol. 2, Dec. 1931, page 309. WLC (10c)

Deep Nitriding by Program Control. J. W. Harsch & J. Muller (Leeds & Northrup Co.). *Metal Progress*, Vol. 21, Jan. 1932, pages 74-76, 94.

Variables in nitriding, materials in the reaction zone, temperature, time during which the reaction proceeds and the rate and manner of flow of the active agent are discussed. Operations of commercial nitriding are proper heat treatment, cleaning and charging of the work, sealing and flushing the chamber free of air with NH_3, heating the chamber, holding the work and chamber at temperature for proper time, and cooling the work and chamber. A duplex cycle of temperatures is described to attain high surface hardness and gradual drop from surface to core hardness. Any program of temperature cycle to give desired results as to penetration and hardness may be designed and controlled with proper instruments. Critical factors in nitriding cycles are discussed. The Electrical Weldability of Silicon Bearing Structural Steels. (Die elektrische Schweissbarkeit des Siliziumbaustahles.) Hochheim. *Die Wärme*, Vol. 54, June 26, 1931, pages 493-494.

Tests on two structural steels with 1% Si (0.12% C) and 0.8% Si (0.20% C) disclosed that no harmful effect is exerted by Si on the welding properties. EF (11c)

Determines Heat Distribution in Torch-Cut Structural Steel. R. L. Geruso & T. N. Hannant. *Steel*, Vol. 89, July 16, 1931, pages 39-40.

As steel becomes brittle when heated to 572° F. it was the question how structural steel was influenced when cut or welded by the oxy-acetylene torch. From a series of tests it could be concluded that temperatures do not exceed 510° F. and that only mild heat stresses below those required for safety are generated when the preheating flame is run over the line of cut. Ha (11c)

The Strengthening of Welded Joints by Cross Straps. E. Hoehn. *Engineering*, Vol. 131, Apr. 17, 1931, pages 525-526.

Author made series of tests on reinforced welded joints. Cover straps were applied across the joint and welded into place. Tests showed that these are best arranged on opposite sides of the plates with the outer strap directly over the inner. Straps properly applied reduce the stress on a welded joint by 30% or more. Diagrams are given showing the method of testing. LFM (11c)

Reinforced Concrete Construction and Welding Technique. (Eisenbetonbau und Schweisstechnik.) R. Hoffmann. *Beton und Eisen*, Vol. 30, Aug. 1931, pages 284-285.

The replacement of the universally used tied joint by welded joints, their greater economy, superior rigidity and other favorable structural properties in reinforced concrete construction are reported. Attention is directed to the utilization of the spot welded fabric for structural work and some future possibilities of welding along this line are touched upon. EF (11c)

Some Methods and Effects of Machine Gas Cutting. L. M. Curtiss. *Western Machinery World*, Vol. 22, Dec. 1931, pages 547-550; *Iron & Steel of Canada*, Vol. 15, Feb. 1932, pages 13-14, 24; *Industry & Welding*, Vol. 3, Jan. 1932, pages 1-5, 24; *American Machinist*, Vol. 75, Nov. 19, 1931, pages 784-785.

The methods of machine gas cutting heavy plates and the metallurgical effect upon the metal cut as well as the economics of the problem are discussed. There has been considerable discussion, especially among the users of steel plate, as to the effect of gas cutting upon the material cut. When observed microscopically, the cut edge is found to be materially altered as compared with the original metal. Apparently this is a physical change, as the pearlitic steel has been transformed into an unstable condition, taking one of 3 forms: sorbitic, troostitic or martensitic, according to the amount of carbon present and the speed with which the metal has been cooled. Considerable grain growth also occurs at the cut edge. The carbon content of the cut edge is also higher than the original metal. This is attributed to the fact that the pearlite patches in the original steel were absorbed while passing through the transformation range, forming austenite; the ferrite was thrown out of solution on cooling. Annealing or normalizing a gas cut piece will restore the original properties of the material. OWE + RHP + Ha + WAT (11c)

Technique in Stamping and Resistance Welding (Stanzereitechnik und Widerstandschweissung.) Felix Goldman. *Maschinenbau*, Vol. 10, Aug. 6, 1931, pages 489-492.

Discusses the influence of resistance welding on strength, the science of resistance welding, weldable materials and strength, welding practice, construction of the apparatus, methods, loads and costs, welding procedure, preparation of the welding rod, effect of welding on the material, and testing of welds. MAB (11c)

Health in Welding Shops. W. von Gonzenbach. *Welding Journal*, Vol. 28, Nov. 1931, pages 344-345.

Paper read before the Tenth International Congress of Acetylene and Welding Industries, Zurich, July 1930. The author, an industrial hygienist, discusses the chemical and physical dangers to health of oxy-acetylene and arc welding. Good ventilation and proper protection from sparks, dazzling light and infra-red rays are essential. Instruction and education of workmen is suggested. TEJ (11c)

V or X-shaped Seams? (V oder X Nähte?) E. Höhn. *Die Wärme*, Vol. 54, Nov. 28, 1931, pages 885-887.

Although, on account of the smaller cross sectional area, the X-shaped seam requires both less material and work, the V-shaped seam has apparently been preferred by the shops for the same sheet size. The adequacy of both seam profiles are critically discussed from the view-point of internal stresses. The valuation resulting seems to speak in favor of the X-shaped seam. The soundness of the V-shaped seams is endangered to a larger extent due to the occurrence of blow-holes, notches and other discontinuities. EF (11c)

Gas Cutting Alters Steel Structure. L. M. Curtiss. *Machine Design*, Vol. 3, Dec. 1931, page 31.

As gas-cutting changes the pearlitic structure it is necessary to anneal the steel after cutting, or preheat the steel which will prevent the change to some extent. Ha (11c)

Machine Gas-Cutting Heavy Plate. L. M. Curtiss. *Steel*, Vol. 89, Nov. 16, 1931, pages 31-33, 38.

Some results of comparison between acetylene and gas-cutting of heavy plate are given. There is usually an increase in carbon on the outside gas-cut edge, and a hardening effect takes place. This effect can be eliminated if the steel is preheated before gas-cutting. The depth of penetration of the altered zone has been found to have a definite relation to the thickness of the material cut; this relationship is shown on a chart. Ha (11c)

Frame for Astronomical Telescope. A. F. Davis. *Journal American Welding Society*, Vol. 10, Nov. 1931, page 8.

In order to save weight and give a structure with a minimum of deflection, arc welded steel construction was used for a large telescope tube. TEJ (11c)

Oxygen Machine Cutting. *Industrial Gases*, Vol. 12, Mar. 1931, page 23.

Deals with fuel gas used with O, acetylene, coal gas, and H, citing advantages of each. DTR (11c)

Welding Alloy Steels Improves Ordnance. *Metal Progress*, Vol. 18, Nov. 1930, pages 68-74.

Developments in welding practice using the X-ray as a guide are described. The Watertown Arsenal has made marked improvements in welding technique and quality of ordnance structures by the X-ray development of welding methods. WLC (11c)

New Washer Punch Press of All-Welded Rolled Steel Construction. Everett Chapman (Lukenweld Inc.). *Journal American Welding Society*, Vol. 10, Nov. 1931, pages 43-44.

Description of a large punch press; the housing, outboard bearing assembly, gears, pinions, flywheel and other parts of which were fabricated by gas-cutting, forming and arc welding of rolled steel plates and slabs. A reduction of over 2⅛ tons in the total weight of the press was accomplished through efficient design and more economical distribution of metal. TEJ (11c)

The Oxy-Acetylene-Welding in the Building of Pipe Lines. (Die Azetylen-Sauerstoffschweissung im Rohrleitungsbau.) H. Buchholz. *Autogene Metallbearbeitung*, Vol. 24, Dec. 1, 1931, pages 351-355.

This method is particularly suitable for welding pipe lines as oxide-constituents and gas inclusions are kept away from the melt and the weld possesses a high strength and great elongation. Besides, oxy-acetylene welding guarantees a dense weld. Illustrations and tests are given of joints and flanges. Ha (11c)

New Type of Hydrogen-Air Blowpipe for Lead-Burning. *Industrial Gases*, Vol. 12, Mar. 1931, pages 37-38.

New type of portable blowpipe for repairs in out-of-the-way places. It is not to replace blowpipes using O with fuel gas. Gives details of tests and shows specimens of work on lead and pewter. DTR (11c)

The Welding of Alloys. *Industrial Gases*, Vol. 12, June 1931, pages 93-97.

Reprinted from *Oxy-Acetylene Tips*, Vol. 6, Feb. 1931, together with excellent pointers. Practically all types of alloys, ferrous and non-ferrous, can readily be welded by the oxy-acetylene process. Most alloys have qualities peculiar to themselves, which of course require slight alterations from the standard welding practice. The various details of these slight alterations are given for Cr and Cr-Ni steels, Mn steels, Mo, V and Si-Mn-Cr steels, Si irons, Al and its alloys, Ni and monel metal, Cu and its alloys. DTR (11c)

Welding Aluminum. *American Metal Market*, Vol. 38, June 13, 1931, page 4.

Reprinted from instruction bulletin of Aluminum Company of America. Expert and detail instructions for gas torch, metallic arc and carbon arc welding are given. Also for the welding of castings. The types of fluxes, size and kind of flame, thickness of metal, preparation of material, kind of welding rods, etc., are thoroughly explained. DTR (11c)

Fast Welding Cuts Line Costs. *American Gas Journal*, Vol. 135, Oct. 1931, pages 59-60.

Description and discussion of the new Lindeweld process of oxy-acetylene welding. Labor and materials costs are said to be reduced while construction is speeded up. CBJ (11c)

Fusion-Welded Drums Authorized by A.S.M.E. Boiler Code Committee. *Power*, Vol. 74, July 21, 1931, page 107.

After 10 years of study and discussion, power boiler drums fabricated by fusion welding have been authorized by the Boiler Code Committee of the American Society of Mechanical Engineers. Welding requirements are specifically outlined for 3 classes of vessels. Class 1 vessels may be used for any purpose without restriction. Class 2 vessels may be used for any purpose except for holding lethal gases or liquids, or holding any liquids at a temperature of 300° F. or above. The maximum pressure at which any vessel can be operated is 400 lbs. and the maximum temperature 700° F. The maximum plate thickness is 1½ in. Class 3 includes all vessels covered by this code not exceeding ⅝ in. plate thickness and used for the storage of gases or liquids at temperatures not materially exceeding their boiling temperature at atmospheric pressure, and at pressures not to exceed 200 lbs. or temperatures not to exceed 250° F., and providing also that the gases or liquids are not lethal. Class 1 vessels and boiler drums must have X-ray examination and stress relieving by over-all heating. The requirements for fusion-welded boiler drums are: a joint efficiency of 90%; tension bend and specific gravity test pieces taken from a continuation of the weld; the bend test specimen, transverse to the welded joint, to show a fiber elongation of 30% without cracking; a minimum specific gravity of the weld metal of 7.80; X-ray tests for plate thicknesses of 3 in. and less; heating the shell, in toto or by sections, to at least 1100° F. for 1 hr. per in. of thickness. Riveting (11d)

Rivets in Metal Airplane Structures. (Das Nieten im Metall-Flugzeugbau.) Erich Rickert. *Maschinenbau*, Vol. 10, Aug. 6, 1931, pages 502-504.

Reviews the work of Pleines (See *Metals & Alloys*, Vol. 2, May 1931, page 104) concluded in 1928 on the riveting material used in Germany for airplanes. Discusses the present status of riveting for such structures. The same methods of manufacture for this kind of rivet can be used for other industrial construction purposes. MAB (11d)

Eliminating Scale on Rivets. D. J. Champion. *Boiler Maker*, Vol. 31, Jan. 1931, page 23.

By using a different shaped head when driving than one which conforms exactly to the style of head originally found on the rivet, the scale on the head will be broken. Ha (11d)

Melting & Refining (12a)

Deoxidizers and Fluxes. G. L. Bailey. *Foundry Trade Journal,* Vol. 46, Jan. 7, 1932, page 6; Jan. 21, 1932, pages 57-60; *Metal Industry,* London, Vol. 40, Jan. 8, 1932, pages 31-34.

An article dealing with non ferrous metallurgy, in which the author discusses first the subject of deoxidizers, pointing out that these materials must be capable (1) of reducing existing oxides and (2) of being readily removed from the bath subsequent to their reaction with the oxides in the bath. Discusses the relationship between heat formation and affinities for oxygen at high temperatures and points out that the heats of formation are roughly indicative of the value of various elements as deoxidizers. The behaviour of common deoxidizers is dealt with, special attention being directed to P and B. The uselessness of Al as a deoxidizer is referred to. Some reference is also made to the alkali and alkaline earth metals in this connection. Attention is directed to the recent work on the deoxidation of metals by reducing gases. The latter part of the paper deals with fluxes, these being defined as (a) solvents for metallic oxides, (b) inert covers to protect metal from oxidation and gas absorption, (c) materials for the removal of impurities other than oxygen, (d) volatile salts which remove inclusions by mechanical action, and (e) degasifiers. Special attention is directed to the fluxes which have proved of value in the manufacture of Al, Mg and light metal alloys. 2 tables and 8 photographs. PRK+OWE (12a)

Carbon-Oxygen Equilibrium in Liquid Iron. H. C. Vacher & E. H. Hamilton. *Rolling Mill Journal,* Vol. 5, Mar. 1931, page 210.

Abstract of a paper presented at the New York Meeting of the American Institute of Mining and Metallurgical Engineers, week of Feb. 16, 1931. See *Metals & Alloys,* Vol. 2, July 1931, page 134. JN (12a)

Iron and Aluminum in Brass Scrap. Edmund R. Thews. *Metallurgist,* Nov. 1930, pages 165-166; Dec. 1930, pages 188-189.

The most important impurities in brass scrap are Fe and Al. Loose Fe is generally removed from brass scrap by magnets. The disadvantages characteristic of more than minute iron contents in common brasses are primarily due to the affinity of iron for carbon and to the low degree of solubility of the iron-carbon compounds in brass. This leads to the formation of extremely hard inclusions concentrated especially along the surfaces of the castings, rendering cutting and finishing treatments exceedingly difficult, if not impossible. Iron carbides are prevented from formation either by increasing the degree of solubility of iron in the brass or by decomposing the carbon compound before casting. The solubility of Fe in brasses increases with the Zn contents, but even the highest Zn contents of commercial brasses do not suffice to dissolve considerable quantities of metallic Fe, such as are accidentally introduced in the form of scrap Fe or to prevent the combination of such Fe with C. Mn tends to increase the separation of Fe from its solution in brass. All brass scrap believed to contain considerable quantities of scrap Fe should be fused at minimum temperatures, preferably in crucible furnaces. Occasional skimming during the melting-down period and the addition of Cu scale to the melt after bringing it up to casting temperatures will remove a large proportion of the Fe. Final decomposition of the iron carbides contained in brass alloys is effected by washing the melt—at full casting temperatures—with a slag consisting of a mixture of equal parts of soda ash and silica sand, the total quantity of slag mixture employed for this purpose amounting to about 3% of the weight of the metal. By this treatment, the carbides are dissolved; the carbon is oxidized; all the iron is absorbed by the brass. The Fe is not removed by this process, but since Fe in solution, while hardening the brass, does not spoil the brass for cutting and finishing, this consideration is of comparatively small importance. If it is desired to effect a reduction of the Fe contents, liberal additions of potassium sulphate should be made during the melting down process; part of this salt is added with the cold charge. The slag formed must, however, be removed before adding the soda ash silica sand mixture, the decomposing influence of which on the iron carbides is considerably reduced by the sulphate. Small percentages of Al may be removed by treatment of the melt with potassium sulphate; the process is carried out as indicated for Fe. However, if this type of scrap is to be employed in the production of high-grade material, it should first be remelted and refined separately, and the ingots produced then added to the virgin brass. Scrap containing considerable quantities of Al should never be used in bulk. The raw material should be remelted and treated with potassium sulphate and the ingots produced added in very small amounts to brass alloy melts of medium quality. The attempt should never be made to use the Al contents of the scrap to make up part or all of the percentage of this constituent in the alloy to be produced. Excessive formation of oxides and dross will remove so much of the original Al as to render accurate calculations useless. VVK (12a)

Flotation of Graphite in Cast Iron. A. L. Norbury & C. Rowley. *Foundry Trade Journal,* Vol. 45, Sept. 24, 1931, page 198.

The authors point out that it is common knowledge that graphite rises to the surface of ladles of molten metal in the case of high total C, hyper-eutectic iron, but it is probably not so generally recognized that graphite can float upward in the partly solidified metal in the case of relatively low total-C cast iron of the cylinder type, which contains as little as 3.3% total C and 1.5% Si; that is to say, which contain much less C than the eutectic composition and consequently have a longer freezing range. Analyses of the total C content of gray pig iron at various points from the top to the bottom of the face of the fractured pig show that graphite does float upward as the pig solidifies. The authors support this contention by quoting various examples of this phenomenon and employ their findings to support the view that graphite is deposited directly from the melt. See also *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 44. OWE (12a)

Casting & Solidification (12b)

Recasting of Bearings in Automobile Repair Work. (Lagerausgiessen bei Automobil-Reparaturen.) K. Haase. *Deutsche Motorzeitschrift,* Vol. 8, Nov. 1931, pages 390-393.

The salient features of a die-casting machine for casting bearings under pressure is described at length. The deficiencies associated with other methods are critically discussed. The author pays attention to furnishing the proof why the new method is more efficient and cheaper on one hand and why the cast bearings are qualitatively superior on the other hand. EF (12b)

The Application of Water-Cooled Molds For Casting Steel. (Die Verwendung wassergekühlter Kokillen zum Giessen von Stahl.) W. Hessenbruch & W. Bottenberg. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, report 188, 1931, pages 205-213; *Stahl und Eisen,* Vol. 51, Dec. 24, 1931, page 1600.

200 kg. ingots of high speed steel, tool steel, stainless chromium steel, and Cr-Ni steel. Melts which had been made in an electric furnace were alternatingly cast in common gray cast iron molds and in a water cooled copper mold. The dimensions of the ingots cast in the 2 types of molds were practically the same. Primary crystallization, appearance of fracture, micro-structure and segregations were studied. During the casting in the water cooled mold the amount of heat taken up by the water was determined. The temperatures of the water increased to about 40° to 50° C. during the casting. The cooling water consumption amounted to about 15 to 20 liters per kg. The ingots were stripped at a temperature of about 900°-1000° C. at the surface. There were no objections as to the appearance of the fracture of the ingots cast in the 2 types of molds. Cracks and pipes were not found in the water cooled ingot when a hot top was used. The primary structure was alike in both cases, and there were no differences as to microstructure and grain size. The segregation of the water cooled ingot in the vertical direction is rather small, but the segregation is somewhat more pronounced in horizontal direction, but as a whole the segregation is not essentially affected by water cooling. In every respect the differences caused by the 2 mold types are rather insignificant. It is shown that the casting temperature much more affects the structure than the type of the mold. The surface of the water cooled cast ingots is much smoother than that of the normal cast ingots. In comparison with the cast iron mold the durability of the copper mold is unlimited. 10 references. GN (12b)

On the Solidification Shrinkage of Carbon Alloys of Manganese, Nickel and Cobalt. Kota Honda, Yosiharu Matuyama & Tadatugu Isobe. *Science Reports of the Tohoku Imperial University,* Sendai, Japan, Vol. 20, Oct. 1931, pages 594-598.

The measurements were made with a thermo-balance; the change of volume during solidification was measured as follows:

Metals	Manganese	98.9% Mn -1.1% C	97.8% Ni -2.2% C	97.8% Co -2.2% C
$\frac{\delta V}{V}$ (%)	-4.5	-1.60	+2.06	+2.03

While Mn and its alloy with C contract, like other metals and alloys, Ni and Co expand; they form an eutectic with C. Since the density of solid C is very small compared with Ni and Co, a great expansion must take place when during solidification C dissolved in these molten metals separates as free C whereas under the same conditions Ni and Co contract; the result of these 2 opposite effects may be positive as actually observed. The case is analogous to that of gray cast iron during solidification. 7 references. Ha (12b)

Centrifugal Casting Process Produces Cylinder Linings Having Superior Wearing Qualities. J. E. Hurst (Sheepbridge Stokes Centrifugal Casting Co., Ltd.). *Automotive Industries,* Vol. 64, June, 1931, pages 882-884.

Shrinkage defects and subcutaneous blowholes due to the defective feeding of the inner central portion in sand castings are eliminated in centrifugal castings. For heavier castings, for use as locomotive piston valve liners and large piston ring drums, the composition of material complies with requirements of "Spun-Sorbitic" patent: the material is of a low Si content and possesses a complete eutectoid structure. After solidification the material is specially cooled. The large grain size is eliminated; this is the chief disadvantage of pearlitic cast iron. Other harder cast iron alloys are used also. One of the latter type contains Mn and Cr and can be used either in its "as-cast" condition or in the oil-hardened and tempered condition. The Brinell hardness of as-cast material ranges from 260 to 320, and of the tempered material from 320 to 475. The tempering is done by heating liners to 850° C. for 10-15 min. and quenching in oil. DTR (12b)

On the Influence of Manufacturing Conditions upon the Properties of Cast Iron Rolls. Kohei Taniguchi. *Seitetsu Kenkyu,* Nov. 1931, pages 224-238.

Under different conditions 3 kg. of roll material, containing 3.11 % C, 0.58 % Si, 0.57 % Mn, 0.592 % P, 0.038 % S, were cast into two molds. A mold was made of sand, in one side a cast iron block being attached. The other mold was made of a porcelain tube heated in a nichrome furnace. By these molds the structures of chilled and sand rolls (or inner part of chilled roll) was obtained, respectively. Hardness of chilled surface and depth of chilling for the chilled castings were measured, and hardness, tensile strength and toughness for the sand castings were also measured. From these results, the influence of the manufacturing conditions upon the properties of cast iron rolls was deduced as follows: High melting temperature and high casting temperature are both favorable to make them as high quality as possible for both chilled and sand rolls, if no trouble is met in practical operation. The most beneficial thickness of iron mold for chilled roll is about 1/3 of the diameter of roll body. The effect of the temperature of mold on the depth of chill was studied. Copper or aluminum mold was tried instead of cast iron mold to increase its chill effect, but the result was not so effective as expected, owing to the formation of a remarkable clearance between mold and roll body immediately after pouring. ST (12b)

The Cooling of Ingots in Molds, Especially of Brass Ingots in Water-Cooled Molds. (Ueber die Abkühlung von Blöcken in Kokillen, insbesondere von Messingblöcken in wassergekühlten Kokillen.) W. Roth. Doctor's thesis, Technische Hochschule, Aachen, 1930. 27 pages.

Small cylindrical ingots of 70 : 30 brass, 15 cm. diameter by 20 cm. high were cast in a thin-walled water-cooled copper mold, in straight and tapered heavy and thin walled cast iron molds, and in dry sand.

Pouring temperature, casting time, and rate of flow of cooling water in the case of the water-cooled mold, were varied. Temperature gradients and cooling rates were determined and compared with mathematical theory. The data are plotted in detail. The time to freeze could be changed 50% by a 15% change in rate of flow of cooling water.

Although the equilibrium diagram indicates that 70 : 30 should have a freezing interval, it was experimentally found to freeze at constant temperature when cooled rapidly. This is claimed to avoid segregation. While material segregation was found in the sand castings the iron mold appeared to avoid it as well as the water cooled mold.

Macro-etching showed the finest grain size on casting from the liquidus temperature into water cooled molds. The next finest grain, with a small transcrystalline outer zone was obtained by casting from 80° C. above the liquidus into a heavy walled iron mold and jarring it during solidification. HWG (12b)

Staveley Sand-Spun Pipes. *Gas Journal*, Vol. 195, July 8, 1931, page 101.

Reviews the pamphlet put out by Stavely Coal and Iron Company Ltd., explaining the firm's process for producing cast-iron pipes by centrifugal casting in dried sand molds, rammed in metal flasks and revolving at high speed until the pipes solidify. MAB (12b)

A New Machine for Centrifugal Casting. (Une nouvelle Machine pour Coulée centrifuge.) Delcroisette. *Revue de Fonderie Moderne*, Vol. 26, Jan. 10, 1932, page 9.

Description of an English casting machine which can be operated by one man. Ha (12b)

Bottom-Cast Practice. Part 17. Edmund C. Bitzer (Mine & Smelter Supply Co.). *Blast Furnace & Steel Plant*, Vol. 19, Dec. 1931, pages 1572-1576, 1587.

Comparison of advantages and disadvantages of bottom casting with those of top pouring. The method of bottom casting is described and the design of stools, runner brick and molds is discussed. Piping and segregation in bottom-cast ingots are considered. MS (12b)

Slush Casting of Aluminium Utensil Spouts. Robert J. Anderson. *Metal Industry*, London, Vol. 40, Jan. 1, 1932, pages 7-10.

Any commercial Al alloy can be used to make a slush cast spout, which is low in cost, has an excellent surface finish, is thin-walled, and of uniform thickness. Factors such as mold design, pouring and finishing are discussed. PRK (12b)

Rolling (12c)

Motors and Control for Rolling Cold Strip Steel. Francis Mohler. *Steel*, Vol. 89, Nov. 30, 1931, pages 31-32, 36; Dec. 14, pages 31-33.

The installation of a four-high-roller-bearing mill is described. The methods of control for maintaining the tension of the strip between mill stands and the necessary equipment is described and illustrated. Ha (12c)

Developments in Sheet Mill Practice. Edward S. Lawrence. *Sheet Metal Industries*, Vol. 5, May 1931, pages 13-16; June 1931, pages 87-91; July 1931, pages 167-168.

Part I outlines recent developments in the equipment for the handling of sheet. Pair heating furnaces, pack heating furnaces, and conveyor systems are discussed. Part II reviews recent patents covering reduction of bars and packs to gage, continuous rolling, normalizing and annealing furnaces, conveyors and pickling machines. The third part discusses patents covering new pickling devices together with those covering annealing boxes. AWM (12c)

French vs. American Sheet Steel. Ed. S. Lawrence. *Heat Treating & Forging*, Vol. 17, Feb. 1931, pages 133-136, 138.

A thorough investigation of French and American practice in the manufacture of sheet steel shows that the sheet bar used by French mills is not as homogeneous in analysis and structure as the sheet bar used here. The present differences in processing can be summarized as less elongation in cold rolling and utilization of continuous normalizers for the second anneal, thus replacing box annealing. Ha (12c)

German versus American Sheet Steel. E. S. Lawrence. *Heat Treating & Forging*, Vol. 16, Sept. 1930, pages 1156-1158.

The author compares the methods employed in America and Germany for the production of steel sheets. Ha (12c)

British versus American Sheet Steel. Edw. S. Lawrence. *Heat Treating & Forging*, Vol. 17, Oct. 1931, pages 955-958.

A comparison of British and American methods of processing full finished sheet steel leads to the conclusion that the irregularity of grain structure in the majority of high grade sheet steels as double box annealed in Great Britain indicates the necessity for basic normalized sheet. American mills could well adopt the lower range of C contents. Ha (12c)

American Rolling Mill Construction (Eindrücke aus dem amerikanischen Walzwerksbau). A. Koegel. *Stahl und Eisen*, Vol. 51, Nov. 26, 1931, pages 1468-1478.

Paper before the Annual Meeting of the Verein deutscher Eisenhüttenleute, Nov. 28, 1931, at Düsseldorf. The average of the American rolling mills is superior to German rolling mills as far as production and saving of manual labor goes. Numerous newer American mills for the production of billets, slabs, beams, rails, all kinds of merchant shapes, rods, plates, sheets, hoops, etc., are described and shown in sketches. Rolling mill furnaces are briefly discussed, as well as bearings, cold rolling and wire drawing. GN (12c)

The Cold Roll Forming of Metal Retainer Strips. D. A. Johnston (Kane & Roach, Inc.). *Metal Stampings*, Vol. 4, May 1931, pages 401-404.

Illustrates and describes layout of 9 sets of rolls used in the cold roll forming of gypsum board retainer strip. JN (12c)

Seamless Steel Tube Manufacturing Methods. G. P. McNiff (National Tube Co.). *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 127-128, 140.

Abstract of a paper presented before the American Society for Steel Treating, Western Metal Congress, San Francisco, week of Feb. 16, 1931. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 224. JN (12c)

The Design of Rolls for Cold Roll Forming Machines. D. A. Johnston (Kane & Roach, Inc.). *Metal Stampings*, Vol. 4, June 1931, pages 489-492.

A chart developed by the author is furnished for determining the length of arc in any given bend from 5° to 90°; such bend having an inside radius of 1/64 to 5/16 in. and being made from stock 0.005 to 0.200 in. in thickness. JN (12c)

Analysis of Rolling Forces. John H. Hitchcock. *Rolling Mill Journal*, Vol. 5, Sept. 1931, pages 583-586; Oct. pages 659-660.

Theoretical discussion and development of formulas for the calculation. Ha (12c)

Location of the Neutral Line in a Roll Pass. Walter Dahl. *Rolling Mill Journal*, Vol. 5, Aug. 1931, pages 555-557.

A method for determining the neutral line is described and rolling troubles due to the wrong position of the neutral line in a profile pointed out. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 313. Ha (12c)

The Composition of Modern Roll Metals. Part I. John H. Hruska. *Rolling Mill Journal*, Vol. 5, Mar. 1931, pages 163-166.

The chemical analyses of a number of common roll metals—cast iron, cast steel and alloy steels—are given, with a discussion of the properties and uses of the manufactured rolls and the influence of various individual chemical constituents. JN (12c)

Recent Development in Cooling Bed Construction. (Neuere Kühlbettbauarten.) M. Curth. *Stahl und Eisen*, Vol. 50, Jan. 16, 1930, pages 65-70; Jan. 23, 1930, pages 99-105; Translated in *Rolling Mill Journal*, Vol. 4, Aug. 1930, pages 423-426; Sept. 1930, pages 493-494; Dec. 1930, pages 691-694.

Report 73 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The requirements which cooling beds of high capacity have to meet are outlined. The disadvantages of older types of mechanical cooling beds are discussed and a detailed, illustrated description of modern constructions of cooling beds is given. The article also mentions improvements in mechanical piling of the bars after they have been cut to size. GN + MS (12c)

Antifriction Bearings Aid Progress of Backed-Up Mills. M. D. Baughman (E. W. Bliss Co.). *Steel,* Vol. 88, Feb. 19, 1931, pages 35-37.

The first large cluster mill for cold rolling wide sheets was installed in the Huntington, W. Va., plant of the International Nickel Co. in 1924. This mill was equipped with babbitted bearings. In 1930 the bearings on the necks of the backing rolls were replaced with roller bearings. This effected a considerable saving in power and maintenance costs. The use of antifriction roller bearings on roll necks and on other parts of rolling mills was initiated by the Timken Roller Bearing Co. and furthered by the E. W. Bliss Co. The successful application of roller bearings to mill rolls depends on proper mounting, adequate lubrication, and freedom from overloading. The successful production of flat stock true to gage depends on proper control of the expansion and crowning of the rolls during operation. JN (12c)

Devices and Application for Steel Mill Roll Neck Lubrication. Discussion. *Iron & Steel Engineer,* Vol. 8, Apr. 1931, pages 178-195.

Discussion by representatives of the lubricant makers and 9 users of rolling mill equipment of the problem of roll neck lubrication. WLC (12c)

Sheet and Tinplate Rolls. An Investigation into the Roll Loads, Stresses and the Causes of Roll Breakage. J. Selwyn Caswell. *Sheet Metal Industries,* Vol. 4, Dec. 1930, pages 649-654; Jan. 1931, pages 757-758; Feb. 1931, pages 851-856; Mar. 1931, page 933.

Part I. Discussion of the loads set up by the deformation of the iron and of the torsional loads, giving the formulae used in the calculation of both. Part II. Further work on the calculation of maximum torque is taken up. Part III. Discussion of the stresses set up in a roll while in the foundry. The author divides a cooling roll into 4 zones and discusses cooling rates in each. Part IV. A short discussion on the alteration in the stresses after stripping the molds. See also *Metals & Alloys,* Vol. 2, Dec. 1931, page 313. AWM (12c)

Plastic Shaping in Calculation and Test (Ueber bildsame Formgebung in Rechnung und Versuch). E. Siebel. (Technische Hochschule Stuttgart). *Stahl und Eisen,* Vol. 51, Nov. 26, 1931, pages 1462-1468.

Paper before the Annual Meeting of the Verein deutscher Eisenhüttenleute, Nov. 28, 1931, at Düsseldorf. 19 references. The paper gives a résumé of past and recent investigations on the various processes of plastic shaping, such as forging, rolling, drawing, extruding. These technical processes are discussed and examples given: energy consumption, losses occurring and the course of the deformation. Methods are described to determine the distribution of pressure between rolls and rolled material. Knowledge of the distribution of pressure in rolling is of importance inasmuch as it is closely related to the flow of material. It is noted that the actual conditions cannot be found and represented by calculations. GN (12c)

The Cold-Rolling Book (Kaltwalzbuch). Edited by Martin Boerner. Martin Boerner Verlag, Halle-Saale, 1929. Paper 6 x 9 inches, 100 pages. Price 6.50 RM.

This has been compiled with the coöperation of A. Pomp, F. Heinrich, W. Quick, E. Schelisch and O. Saltmann. It is a rather elementary and practical discussion of the ordinary cold-rolling process for steel. The description of the change of properties by cold-rolling and annealing is the most technical part of the brochure. High roll pressure and high rolling speeds are advocated, with very heavy rolls and great care in lubrication and cooling. This is considered better engineering than the American practice of continuous rolling. Rapeseed oil plus 15% flake graphite is advocated for bearing lubrication.

Erichsen testing is briefly discussed. The book ends with "Ten Commandments for the Cold-roller," dealing with care of the rolls and precautions in the process, and tells the workman that if he observes these commandments he will aid in allowing Germany to compete with foreigners and hence retain his own job. Tables showing pass reductions for different conditions are appended.

H. W. Gillett (12c) -B-

The Basis of Continuous Seamless Tube Rolling Mills without Mandrel (Ueber die Grundlagen kontinuierlicher Rohrwalzwerke ohne Dorn. Reduzierwalzwerke). G. B. Lobkowitz. *Stahl und Eisen,* Vol. 51, Nov. 12, 1931, pages 1389-1397; Nov. 19, 1931, pages 1432-1437.

Report 90 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. 6 references. After describing the 3 various types of reducing mills for rolling small size seamless tubes, the general principles are considered which this type of mills must fulfill. They are as follows: Seamless tube reducing mills differ from other continuous mills inasmuch as the increase of rolling speed of subsequent passes cannot be made strictly correspondent to the decrease of cross-section. The speed of rolls must be regulated so that a pull is always exerted between 2 subsequent passes. The amount of this necessary pull can only be determined by experiment. An approximate method of calculating the excess of speed from pass to pass is given. The distance of subsequent passes decidedly affects the wall thickness of the tubes and must be chosen so that a uniform wall thickness is guaranteed. An attempt has been made to determine, by calculation, amount and distribution of the changes of wall thickness during the rolling process under the supposition of uniform reduction, uniform pull and uniform increase of wall thickness. The deformation process of the 3 various rolling methods was studied and the forces apparent in the cross-section are diagramatically shown as to amount and distribution. The above considerations lead to the following requirements which reducing mills should meet for successful operation. (1) Largest reduction per pass with smallest increase of wall thickness and smallest cooling of material. (2) Avoiding of slip in the passes. (3) Admissibility of every length and thickness of tube. (4) Only driven passes. (5) Smallest number of reducing passes. (6) Shortest distance of subsequent passes. (7) Careful installation of rolls. (8) Correct adjusting of rolls. (9) Small wearing of rolls. (10) Regulation of speed. GN (12c)

Drawing & Stamping (12h)

The Construction and Uses of Typical Dies. Part V. Edward Heller. *Metal Stampings,* Vol. 4, May 1931, pages 431-432.

The author describes and illustrates the design, construction and operation of 2 types of inverted drawing dies, one for drawing cup-like parts and one for deep drawing combined with blanking and piercing operations. JN (12h)

Protective and Safety Devices on Stamping Machines (Schutz und Sicherheitsvorichtungen an Stanzereimaschinen.) H. Haake. *Zeitschrift Verein Deutscher Ingenieure,* Vol. 75, Oct. 31, 1931, pages 1349-1355.

Various constructions are described and illustrated. Ha (12h)

The Use of Compressed-Air Pressure Plates for Non-Ferrous Metal Working. O. Kühner. *Metal Industry,* London, Vol. 38, May 29, 1931, pages 545-547.

Among the advantages of using compressed-air pressure plates instead of spring pressure plates for cutting and cupping in one operation is the constant pressure plate thrust enabling the selection of more satisfactory drawing proportions. See *Metals & Alloys,* Vol. 2, Jan. 1931, page 12. PRK (12h)

The Design of Simple Bending Dies. Ellsworth E. Clark (Westinghouse Elec. & Mfg. Co.). *Metal Stampings,* Vol. 4, May 1931, pages 395-398, 413-414.

Describes and illustrates dies for producing "L", "V", and "U" bends, short bends and closed bends such as collars, loops and ferrules in sheet metal stamped parts. The author advocates the complete planning of all press tools on the drafting board. JN (12h)

The Drawing Qualities of Sheet Steel. Thos. Dockray. *Metal Stampings,* Vol. 4, Nov. 1931, pages 893-894.

The various tests for ascertaining the qualities of a deep-drawing steel are reviewed and the properties of a steel in relation to the treatment and working are discussed. From tests made, the following conclusions were reached. No correlation was found between the variations of mill cold rolling and the subsequent aging. Above 15% of the sheets showed no variation in Erichsen value in a period of 3 mos.; about 5% showed a slight increase; the remaining 80% showed a decrease up to 12% of the original value. The center of the sheet which contained the most chemical segregation showed the largest proportional decrease. After a certain period of maximum decrease was reached, an increase occurred until the original was reached. Rockwell values varied to the same extent as the Erichsen, but in no constant relation. Often the Rockwell hardness of a given sheet remained practically the same while the Erichsen value varied greatly. Low and high C content did not seem to make any difference. Ha (12h)

Die Construction for Plastic Drawing of Sheet Steel. *Metal Stampings,* Vol. 4, Dec. 1931, pages 996-997.

Paper read and discussed before the American Society for Steel Treating, Sept. 1931. See "Plastic Drawing of Sheet Steel into Shapes," *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 19. Ha (12h)

The Drawing of Wire and its Further Treatment (Drahtzieherei und Drahtverarbeitung). A. Bahls. *Dinglers Polytechnisches Journal,* Vol. 346, Sept. 1931, pages 145-150.

The technique of wire drawing with old types and recent machinery equipment is discussed and data concerning the average output are presented.

Auxiliary machines for straightening and cutting are discussed with reference to their design, mode of operation and economy. EF (12h)

Measurement on the Degree of Orientation in Hard-Drawn Copper Wires. W. A. Wood. *Philosophical Magazine and Journal of Science,* Series 7, Vol. 11, Feb. 1931, supplement, pages 610-617.

An investigation is made of the degree of orientation across the section of hard-drawn copper wire and of the way these measurements differ as the wire is further drawn, and a method is described whereby the degree of orientation may be estimated with the aid of a photometer. A core effect is found to exist; a non-oriented layer encloses an oriented core and the line of demarcation is quite sharp. The results are discussed in connection with the mechanical action of dies. Ha (12h)

Cold Working (12j)

The Effect of Cold-Working on the Magnetic Susceptibility of Metals. K. Honda & Y. Shimizu. *Kinzoku no Kenkyu,* Japan, Oct. 1931, pages 565-582.

The effect of cold-working on the magnetic susceptibility of metals has been studied systematically and may be summarized as follows: The effect of internal stress on the magnetic susceptibility of 10 metals belonging to the cubic system, that is, Cu, Ag, Au, Pb, Al, Pt, Rh, Pd, Mo and Ba, was measured. The magnetic susceptibility of diamagnetic metals that is, Cu, Ag, Au and Pb, decreases by compression. In the case of Cu, its susceptibility is changed from diamagnetic to paramagnetic by compression. The magnetic susceptibility of paramagnetic metals, viz., Al, Pt, Rh, Pd, Mo and Ba, also decreases by compression. The relation between the changes in density and magnetic susceptibility is linear. The temperature effects on the magnetic susceptibility of Pt and Rh are just the opposite of each other, but the effect of the internal stress on the same quantity in the two metals is the same. KT (12j)

Polishing & Grinding (12l)

Paraffin Oil as Lubricant, Cincinnati Grinders, Inc. *Abrasive Industry,* Vol. 12, Oct. 1931, page 26.

Data pertaining to the use of paraffin oil as a grinding lubricant are given. The heavier oils that were originally tried out were too expensive and left too great a residue on the work. The lighter non-viscous oil such as kerosene was too penetrating and had a comparatively low flash point which made the fire hazard rather high. A light paraffin oil served the purpose well, kept the wheel open, and overcame all of the above mentioned objections. WAT (12l)

Care in Polishing for High-Grade Finish, Cadillac Motor Car Co. *Abrasive Industry,* Vol. 12, Oct. 1931, pages 33-36.

Polishing and buffing operations are described and illustrated. WAT (12l)

DEFECTS (13)

Worn Tires and Split Switch Tongues. (Abgenutzte Radreifen und klaffende Weichenzungen.) CAESAR. *Organ Fortschritte des Eisenbahnwesens,* Vol. 86, Mar. 1, 1931, pages 138-143.

The danger of worn tires when passing switches is pointed out particularly for internationally running railroad cars It is attempted to determine how far a wheel can be allowed to wear down to pass safely the tongues of switches. Ha (13)

Crankshaft Fracture in Air Traffic. (Kurbelwellenbrücke im Luftverkehr.) E. EVERLING. *Automobiltechnische Zeitschrift,* Vol. 35, Jan. 10, 1932, pages 22-23.

A statistical review of crankshaft fractures in the last years reveals the fact that the most likely place for a fracture is where a sudden change of section occurs; seldom are defects of material the case. The shape of the fracture points to torsional vibrations. To avoid this cause a simple strengthening of the shaft would not do because of mechanical reasons; the better way is to prevent resonant oscillations by making the shaft hollow. A change of sequence of ignition will sometimes help. The most effective means to prevent fractures of shafts are damping devices for the oscillations consisting mainly in a mass rotating with the shaft but being able to change its position with respect to the end of the shaft. By properly dimensioning mass and friction the resonance curve can be almost entirely smoothed out. It is strongly emphasized that this problem is never a question of material but always of resonance. Ha (13)

Cracks in Circumferential Seams of Water-gas Welded Drums. (Risse in Rundnähten von wassergasgeschweissten Trommeln.) HERMS. *Die Wärme,* Vol. 54, Sept. 12, 1931, pages 682-688.

The formation of cracks after three months' service was noticed in gas welded circular seams of four vertical tube drums. The course and depth of the cracks was determined by drilling and chipping and the repair work is described. EF (13)

Pinholes in Aluminum Castings. NATIONAL SMELTING COMPANY. *American Metal Market,* Vol. 38, Apr. 23, 1931, pages 4, 10.

Printed in *Bulletin* of The National Smelting Company, Cleveland. In non-technical language gives causes of pinholes with practical remedies for removal. DTR (13)

Attempt of a Systematic Classification of Casting Defects. (Versuch einer systematischen Einteilung der Gussfehler.) G. GIERDZIEJEWSKI. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Dec. 4, 1931, page 922.

A distinction is made between outer and inner scrap; the outer depends on the inner. The defects are divided into 10 classes: errors of dimensions, rough surfaces, dirtiness of the sand, interruption during pouring, bubbles, pipes, coldwelding and cracks, inclusion of slag, segregation, errors in composition. The reasons for these defects are also divided in 10 classes: design, pattern or ingot mold, molding sand, mold and cores, evaporation of water in the mold, construction of the mold, melting process, pouring technique, the metal, miscellaneous. Ha (13)

CHEMICAL ANALYSIS (14)

The Practice of Absorption Spectrophotometry. F. TWYMAN. Adam Hilger, Ltd., London, 1932. Cloth, 6 x 9¾ inches, 80 pages. Price 5s 3d.

The precise measurement of the intensity at any given wavelength of the light transmitted by a material provides information which is often quite useful. In atomic and molecular theory, and, in chemical analysis, use is being made of such information.

This little book is intended as a guide to the technique of absorption measurement in the visible, ultra-violet and infra-red regions of the spectrum. It unfortunately treats only instruments made by the publisher. There is no index.
H. W. Russell (14)-B-

Recent Applications of Absorption Spectrophotometry. Adam Hilger, Ltd., London, 1932. Cloth, 6 x 9¾ inches, 44 pages. Price 3s 6d.

A bibliography prepared as a supplement to the Practice of Absorption Spectrophotometry. The literature cited is, in the main, merely classified not abstracted.

A Study of the Electrolytic Determination of Copper in the Presence of Platinic Ion. T. LEONARD KELLY & JOSEPH J. MOLLOY. *Journal American Chemical Society,* Vol. 53, Apr. 1931, pages 1337-1341.

It has been found that the Pt deposits not only over the Cu but through it, causing an increase in weight of the cathode. It is, therefore, recommended that the cathode be weighed after the Cu is dissolved off, instead of weighing before the deposition, in order to obtain the true weight of the cathode. The effects of certain elements on the use of diethyl dithiocarbamate as an indicator for Cu are given.
MEH (14)

Lead, Antimony and Tin Alloys. MAX. HALE. *Chemist-Analyst,* Vol. 20, Mar. 1931, page 10.

The specific gravity of Pb-Sb alloys containing not more than .5% Sn indicates the approximate composition. For analysis .5 g. is decomposed with HNO_3 and neutralized with NaOH until the precipitate redissolves. The solution is poured into 5% NaHS solution and boiled for one hour. The precipitate is filtered, washed with NaHS and dissolved in HNO_3 and H_2SO_4. Pb is determined as $PbSO_4$. 4-5 g. KCN is added to the filtrate from the sulphide precipitation and Sb is electro-plated on Pt electrodes at 3.5-4 volts. The remaining solution is acidified with acetic acid and Sn precipitated with H_2S, ignited and weighed as SnO_2. CEM (14)

The Colorimetric Determination of Minute Amounts of Cadmium. LAWRENCE T. FAIRHALL & LEON PRODAN. *Journal American Chemical Society,* Vol. 53, Apr. 1931, pages 1321-1323.

A colorimetric method for the determination of minute amounts of Cd is described; in it advantage is taken of the intensification of color of the sulphide under ultraviolet rays. A sensitivity of 1:2,500,000 is obtained and an accuracy of 4% in the analysis of material containing from 0.40 to 1.00 mg. of Cd in 100 g. of organic material. MEH (14)

HISTORICAL & BIOGRAPHICAL (15)

Early Forges & Furnaces in New Jersey. CHARLES S. BOYER. University of Pennsylvania Press, Philadelphia, 1931. Cloth, 6 x 9¼ inches, 287 pages. Price $5.00.

The author is president of the Camden County Historical Society, and has been collecting the information contained in this volume for the past 20 years. The treatment is primarily historical, but some interesting metallurgical comments are included.

Little is known about the first New Jersey furnace, the Shrewsbury furnace, established about 1675-1680, but there are good records of several built around 1725. It was known about 1750 that some of the local ore beds were too high in sulphur while others produced cold-short iron, i. e., were too high in phosphorus. By 1825 or before, ores were evaluated for suitability for iron-making by chemical analysis, made by Professor Silliman at Yale. The analyses cited are reported to even percents, except for "phosphate of iron," of which three ores contained 1, 1½ and 2%. Cast pipe, first ordered from Weymouth furnace in 1801 for the Philadelphia water works, was tested at the works, and there was plenty of scrap. Cast iron grave markers made at Weymouth are said to have withstood the weather for 100 years with little signs of rusting, a quality claimed by the early iron founders for iron from bog ore. The author states that he has a piece of bog iron cast at Martha furnace which has lain out in the weather for 10 years without a trace of rust.

The present Taylor-Wharton Iron & Steel Company plant at High Bridge, is the direct successor of the old Union Iron Works, established before 1750, and is located on part of the original tract, the Taylor family having been manufacturing iron and steel at that location for over 150 years.

The services of the various forges and furnaces in making munitions for the Revolutionary War and that of 1812 are interestingly described.

Photographs of the ruins of some of the old furnaces, of cast iron stoves, etc., add to the interest of the volume.

The printing and binding are excellent.

Metallurgists interested in the historical aspects of their science will welcome this book, though fuller discussion of the metallurgical problems and difficulties involved might well have been included. H. W. Gillett (15)-B-

Development of Tungsten Carbide Die. L. C. JACOBSON. *Wire & Wire Products,* Vol. 7, Jan. 1932, pages 18, 26-28.

An outline is given of the difficulties surmounted in the development of the carbide die from its inception to its present use in drawing special shapes. Ha (15)

Michael Faraday, Early Metallurgist. Correspondence from F. G. MARTIN, Birkenhead, England. *Metal Progress,* Vol. 20, Dec. 1931, pages 77-78.

The writer gives a short account of the metallurgical contributions of Michael Faraday. WLC (15)

The Story of the Nickel Industry. A. J. WADHAMS (International Nickel Co.). *Metals & Alloys,* Vol. 2, Sept. 1931, pages 166-175.

The author recounts the history of the development of the nickel deposits of Ontario with interesting details of the part of many individuals in this development. WLC (15)

The Ten Years of the Kaiser Wilhelm-Institut für Metallforschung. (10 Jahre Kaiser Wilhelm-Institut für Metallforschung.) G. MASING. *Zeitschrift für Metallkunde,* Vol. 23, Dec. 1931, pages 321-322.

The foundation and development of the institute are described. The efforts of the institute have been chiefly in two fields: (1) the application of X-rays to physical and metallurgical problems in metals and alloys, (2) the study of the behavior of single crystals. RFM (15)

A Research on Faraday's "Steels and Alloys." ROBERT HADFIELD. *Philosophical Transactions of the Royal Society of London,* Series A, Vol. 230, pages 221-292.

Faraday left a number of steel specimens on which he experimented. On the occasion of his 100th birthday they were subjected by the author to present day analysis and testing of physical properties, the results of which are given in this highly interesting report. The means Faraday had at his disposal are described, and the tests made consisted in chemical analysis, determination of hardness, metallographic examination, resistance to corrosion, specific magnetism, forging properties, determination of critical temperature ranges, thermal expansion, electrical resistance, and tensile tests. Among the 76 specimens were alloys with Cr, Ni, Cu, Au, Ag, Pt, Rh, Pt + Ag, Ag + Au, Ni + Au. Much of our present knowledge is anticipated in the research work of Faraday.
Ha (15)

Cast Iron Pipe 260 Years Old in France. BURT B. HODGMAN. *Journal American Water Works Association,* Vol. 23, May 1931, pages 673-677.

The author describes his visit to Versailles, France, and his inspection of the pumping plant and piping of the Versailles Gardens. The pipe is of cast iron, installed between 1664 and 1685 and is the oldest known. It is approximately 20 ins. in diameter, cast in lengths of 2 meters and flanged. The pipe in places is laid underground outside the tunnel and at other places runs along on the floor of the tunnel. It is in good condition. VVK (15)

Notes on a Research on Faraday's Steels and Alloys. ROBERT HADFIELD. *Engineer,* Vol. 152, Sept. 25, 1931, page 319.

Abstract of paper read before Section G of the British Association for the Advancement of Science, London, Sept. 24, 1931. LFM (15)

Rectification in the Copper-Oxide Cell (Le redressement dans les éléments a oxide de cuivre). R. Jackelet. *Revue Générale de l'Electricite*, Vol. 30, Sept. 5, 1931, pages 365-372.

The theory developed by the author for the explanation of the rectifying action of Cu against copper oxide is based on tests which seem to point to a distortion of the crystal which it assumes in the oxidation furnace. The dissymetry thus produced in the crystals would explain the dissymetric action against the passage of alternating currents. Ha (20)

The Profiles of Chords of Welded Girders (Ueber die Profile der Stäbe geschweisster Fachwerkträger). H. Kayser & C. J. Hoppe. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Oct. 3, 1931, pages 1251-1254.

The results of tests on girders which were made to give a comparison between the strengths of girders as dependent on their construction, rivets, gussets, chord section by measuring the deflection, tensions and breaking loads and also to compare the weights and manufacturing conditions of 4 different constructions of pipes and of profiles. The T-sections were the least satisfactory; pipes gave a good saving in weight. The omission of gusset plates and T-sections gave the least weight. The tests prove that, for welding, new sections and pipes can be used to very great advantage, especially pipes because they have a greater moment of inertia and are, therefore, more resistant to buckling. They can also be welded in angular joints. Ha (20)

The Demonstration of Calculations of Strength in the Welding Technique. (Ueber die Verauschaulichung von Festigkeitsrechnungen in der Schweisstechnik.) Otto Mies. *Die Schmelzschweissung*, Vol. 11, Jan. 1932, pages 1-3.

The method of explaining and making a certain phenomenon in one field of theoretical physics more comprehensible by a similar phenomenon in another field which both have the same mathematical expression, and which has been very fruitfully used by Kirchhoff, Lord Kelvin, Prandtl and Foeppl, is discussed and illustrated by an example of the stresses occurring in a welded ship's shaft, which has a slight irregularity in its section. The influence on the magnitude of the stresses is found by a hydro-mechanical analogue; it is shown that the distribution of shearing stresses follows the same law as the velocity of rotating water in a pipe of circular section. Ha (20)

Parallel Operation of Turbo-Blowers. (Parallelbetrieb von Turbogäsen.) R. Landsberg. *Stahl und Eisen*, Vol. 51, Aug. 27, 1931, pages 1077-1080; Sept. 17, 1931, page 1179.

The parallel operation of turbo-blowers, even of different characteristics, does not offer any difficulties. If the speed remains constant the turbo-blower adjusts itself without exterior regulation to the new conditions brought about by operating another blower in parallel to it on the same pipe line. It is, therefore, sufficient to automatically regulate only one of several blowers working on a common system. Ha (20)

Rebuilding Track under Heavy Traffic. LeGarde. *Electric Railway Journal*, Vol. 75, Dec. 1931, pages 685-688.

Reconstruction of 8,136 ft. of track on Market Street, San Francisco. By efficient mechanical and labor organization, the job was completed in 24 working days. Welding of joints was made by the thermit process. CBJ (20)

Industrial Policy as Affecting the Iron and Steel Industry. Wm. J. Larke. *Foundry Trade Journal*, Vol. 45, Nov. 5, 1931, pages 283-285.

Address at a meeting of the Midland Coördinated Metallurgical Societies, in which the author reviews post-war conditions and the relationship between British policy and the trade depression. OWE (20)

Logical Safety Methods Bring Higher Production. George Laidler. *Canadian Foundryman*, Vol. 22, Oct. 1931, pages 11-14.

An article, accompanied by 1 photograph and 2 tables, in which the various methods that can be adopted for improving safety conditions in factories are discussed in some detail. OWE (20)

Means for a Calculation of Strength which is True to Reality. (Wege zu einer wirklichkeitsgetreuen Festigkeitsrechnung.) Ernst Lehr. *Zeitschrift Verein Deutscher Ingenieure*, Vol. 75, Dec. 5, 1931, pages 1473-1478.

The conceptions of "degree of safety" and "permissible stress" are today still not absolutely definite. Recent investigations show that a calculation of the actually occurring stresses is possible only if the strength-reducing influences are taken into consideration from case to case. These influences can be divided into 2 groups: 1. Those concerning the material itself, injury to surface, corrosion, temperature, kind of stress, defects in manufacture; 2. Influence of shape and of service (notch effects due to design, overstressing). Although the determining material properties, as for instance, endurance limits and alternating stress strength, are sufficiently well known it has not been possible to transmit the results of sample rods to parts of considerable dimensions. To do this the author makes concrete suggestions: static measurements of elongation with defining of zones of maximum stress, dynamic measurement of elongation for the determination of the actually occurring effect and its temporal course, decomposition of the maximum observed stress into two components, one constant and one superimposed alternating force; from these data the material satisfying the requirements is selected. The true safety margin can then be determined according to whether the respective part must be considered as the vital factor or as a replaceable part in the whole structure. 19 references. Ha (20)

American Mining Law. A. H. Ricketts. California State Printing Office, Sacramento, 1931. Limp leather, 5 x 8 inches, 811 pages. Price $2.00.

This is a concise exposition of American mining law. It is very complete, and is undoubtedly authoritative. It is well printed on thin paper and bound in leather. We doubt if the price charged covers the cost of printing and binding. HWG (20)-B-

The Cupola Furnace. J. E. Hurst. *Foundry Trade Journal*, Vol. 45, Nov. 19, 1931, pages 316-318.

An article in which the value of the cupola furnace as an economical unit is emphasized. The cardinal points in melting practice are discussed and the necessity for maximum fuel economy is stressed. The importance of escaping-gas composition and temperature are dealt with. The relationship between maximum thermal efficiency, melting rate, and critical blast volume receives some consideration. Attention is directed to the balanced blast cupola and the value of the increased flexibility of air-supply control of this type of cupola is emphasized. The paper closes with a table showing the costs of producing malleable cast iron in various types of melting equipment. A report of the discussion of the paper follows. OWE (22)

An Engineer's View of the Foundry. Henry Gardner. *Foundry Trade Journal*, Vol. 46, Jan. 7, 1932, pages 7-11.

A discussion of the features in foundry practice of particular interest to engineers: (1) furnaces, (2) melting practice, (3) molding sands, (4) molding appliances and handling equipment, and (5) defective castings. Some attention is directed to the machinability of cast iron, and considerable space is devoted to the effect of core design upon castings. A description of various methods of sand-molding and of molding equipment and handling appliances are given. The article is illustrated by 20 photographs. OWE (22)

Determine Clay Content by Short Method. E. C. Cunningham. *Foundry*, Vol. 59, Nov. 15, 1931, pages 43-44.

Abstract of a report to the Wisconsin Gray Iron Group—Sand Committee on the adoption of a modification of the present American Foundrymen's Association method of clay substance determination in molding sand. The principal advantages of the modified method are: elimination of syphoning and refilling operations and a more uniform application of wash water. VSP (22)

To Produce Better Cast Iron, Standardize Materials and Practice. J. L. Heffron. *Canadian Foundryman*, Vol. 22, Nov. 1931, pages 5-10, 22.

Paper read before the Montreal Chapter of the A.S.S.T. at the opening meeting of the Fall Session, in which a description of the production of better grades of cast iron by improved cupola practice and mixtures and by standardizing raw materials is dealt with in considerable detail. OWE (22)

More Pig Iron for Better Castings. J. E. Hurst. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 77-78.

Recommending the use of more pig. The reduction in Si and Mn and the increase in S and combined C brought about by the remelting of No. 1 pig iron is shown. The relation between character of initial Fe and the effect of remelting is brought out. CHL (22)

Making Large Bells For a Carillon. *Iron Age*, Vol. 129, Jan. 21, 1932, pages 230-231, 250.

Describes the casting of carillon for the Riverside Drive Church at the Croydon Bell Foundry, Croydon, England. Molds are built up largely by hand and are set in pits. Outer cope is formed in specially designed cast Fe case. After casting, metal is allowed to cool for one or two days, depending on size. When taken from sand, the casting is sand blasted, the gate and header trimmed off. Each bell is tested and tuned for five principal tones. VSP (22)

New Ingot Metal Standards. *Metal Industry*, New York, Vol. 29, Dec. 1931, pages 517-518.

Tables are given listing the chemical compositions of copper base alloys in ingot form for sand castings with approximate physical properties and notes on uses, foundry manipulation and machining characteristics. This is part of tentative specification B 30-31 T of the American Society for Testing Materials. PRK (22)

Foundries, Large and Small. *Metallurgist*, Sept. 1931, pages 129-130.

The arguments for and against a foundry in connection with any individual company to supplement their needs are reviewed with the conclusion that only in the largest establishments is such a foundry efficient, satisfactory or justified. VVK (22)

The Magnetic Moulder. *Foundry Trade Journal*, Vol. 46, Feb. 4th, 1932, pages 89-91.

A description of an electrically operated molding machine which has no motor attachment and which requires neither compressor nor hydraulic plant for its working, the entire operation being magnetic in nature. The article is accompanied by 1 diagram and 1 photograph. OWE (22)

Sands and Sand Testing. J. G. A. Skerl. *Engineering*, Vol. 132, July 3, 1931, page 10.

Abstract of a paper read before the Institute of British Foundrymen, June, 1931. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 23. LFM (22)

The Use of Flexible Couplings in Foundries. *Foundry Trade Journal*, Vol. 46, Feb. 11, 1932, pages 103-104.

A brief description of the value of employing flexible couplings for connecting machines and motors and avoiding troubles due to misalignment. Some consideration is given to methods for avoiding end thrust and to points that should be observed in mounting machines for service. OWE (22)

Foundries Requiring Clearer Conception of Gray Cast Iron. Oliver Smalley (Gray Iron Institute). *Steel*, Vol. 88, Feb. 12, 1931, page 42.

Advances in the gray iron industry during 1930 include the control of graphitization and carbide formation in castings as a result of better theoretical conceptions, improvements in operation and in the control of products by the adoption of standard procedures, the application of heat treating methods to gray castings resulting in increased tensile strengths, thus permitting their use for the manufacture of oil quenched machinery parts, tool parts and die parts, and the development of a new and superior corrosion-resistant gray cast iron. FURNACES & FUELS (23)

Modern Developments in Blast Furnace Stoves. T. P. Colclough. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 97-101.

The theories of heat transfer as applied to the checkerwork in blast furnace stoves are interestingly discussed. The advantages gained by the use of varying sizes of fillers in the checkerwork of the Brassert stove so as to increase the volume of the fillers from the top to the bottom of the stove and at the same time maintain the velocity of the gas are discussed. Stoves of the new designs operate with an overall efficiency of over 85% while those of the old design ranged from 50 to 60% in overall efficiency. CHL (23)

The Path of Gases in the Coke Oven. (Der Weg der Gase im Koksofen.) P. Damm & F. Korten. *Glückauf,* Vol. 67, Oct. 24, 1931, pages 1339-1345; *Stahl und Eisen,* Vol. 51, Nov. 19, 1931, page 1437.

Report 38 of the Coking Plant Committee of the Verein deutscher Eisenhüttenleute. At any one moment the coking charge can be divided into preheating zone, plastic zone, semi-coke zone. In each of these, a degasification takes place depending on the type of coal and also on the coking conditions. The volatile matter of the preheating zone migrates to the center of the oven whereas that of the coking zone migrates to the hot walls of the oven. Very little is known of the path of the gases coming from the plastic zone, but the location of this zone in the oven affects the output of by-products, since gases migrating to the hot walls are immediately dissociated. GN (23)

Successful Open-Hearth Operation with Coke Oven Gas. A. J. Ebner (Freyn Engineering Co.). *Blast Furnace & Steel Plant,* Vol. 19, Nov. 1931, pages 1459-1461.

Hoesch Steel Works, Dortmund, Germany, has improved design of open hearth furnaces so that only coke-oven gas is burned. The slag pockets have been the same width as the regenerator chambers and both have a center dividing wall and double arched roofs. A single uptake tapers from a wide opening centrally over the slag pocket, narrowing as it rises to the furnace port. A double burner is provided at each furnace end, each burner receiving gas through a water-sealed gooseneck which permits easy adjustment of burner positions. Use of single air uptake and short furnace head with constricted port produces a high air velocity concentrated at the point of admixture with the gas and results in exceptionally good turbulence and effective flame. Average consumption of gas (527 B.t.u./ft.^{3}) based on actual time of heats from tap to tap on all furnaces is 8390 ft.^{3}/ton of steel. Furnaces are old and do not have the advantages of modern structural improvements. Bricks used average 24 lbs./ton of steel. Water cooling of doors, frames and ports requires an average of 1580 gals./ton of steel. Average production rate on three 100-ton furnaces is 15½ tons/hr. Hearth load is 68 lbs./ft.^{2}/hr. Checker brick is renewed after 1200 heats. Other plants are adopting this type of furnace. MS (23)

The Use of High Frequency Furnaces in the Laboratory (Ueber die Verwendung von Hochfrequenzöfen im Laboratorium). W. Kroll. *Metallwirtschaft,* Vol. 10, Sept. 25, 1931, pages 751-754.

The relative advantages of 2 high frequency electric furnaces for laboratory use are discussed, a Lorenz generator type of 8000 cycles and 4 kw. and a Ribaud spark gap type of 60,000 cycles and 12.5 kw. The generator type is simpler to operate on account of the low voltage required, 100 to 200. The 8000 volts required for the spark gap type makes it more expensive and necessitates perfect insulation between the crucible and furnace and crucibles do not last as long as at lower voltages. In the generator type, 400 g. electrolytic Fe can be melted in 25 mins. with 11 kw., in the spark gap type, 800 g. with 12.5 kw. Too rapid heating must be avoided in the generator type, to prevent local overheating. The spark gap is placed in a box because of its noise and nitrous fumes. Metals with low conductivity and metallic powders can be melted in the spark gap type, but it is better to compress powders into briquettes. Cold Si cannot be melted in either type but at 1000° C. it has enough conductivity to be melted in the spark gap type. Mg and Al cannot be melted in the generator type, but can in the spark gap type. High frequency furnaces are ideal for alloying purposes and produce a thorough mixing action. Metals can be melted under H, A, or in a vacuum. Aluminothermic and magnesio-thermic reactions can be carried out: Pb and Sn can be separated, pure Ca can be produced by distillation, and easily oxidized metals can be melted under A. Quartz is used as a seal against air. Alundum forms a very good crucible material and can be used up to 2000° C. CEM (23)

PC

Economy and Thermal Efficiency of Modern Electric Furnaces for Annealing Metals. (Wirtschaftlichkeit und thermischer Wirkungsgrad neuzeitlicher Elektroöfen zum Glühen von Metallen.) H. Masukowitz. *Zeitschrift für Metallkunde,* Vol. 23, Nov. 1931, pages 306-309; Dec. 1931, pages 335-337.

Fuel costs (producer gas, electricity), heat losses, and general thermal efficiency of annealing furnaces are discussed. Special insulation and construction affords high efficiency. Design of continuous furnaces for annealing metal strip; shaft, pot, and muffle furnace for annealing pipes and rods are described and their economy and thermal efficiency are discussed. RFM (23)

Conditions of Pressure and Draft in the Open-Hearth Furnace. (Druck-und Zugverhältnisse im Siemens-Martin-Ofen.) M. J. Lackner. *Stahl und Eisen,* Vol. 51, Feb. 12, 1931, page 205.

The distribution of pressure and draft in the different parts of the open-hearth furnace, including stack, were studied; the results are tabulated and some conclusions drawn for the arrangement of the chambers, ports, channels, etc. Ha (23)

Technical and Practical Requirements of Modern Forge Furnaces. Wm. Lehrer & A. B. Barber. *American Gas Association Monthly,* Vol. 13, June 1931, pages 250-253.

Based on the work of Jominy, a special type of gas fired furnace has been developed for heating forgings. Temperature and atmosphere are important considerations in this process. High temperatures cause burning of steel and destruction of refractories. The scale formed peels off and, reacting with refractories, produces a low melting flux that may cling to the metal and cause a defective forging. Automatic temperature control enables operation below the melting point of the scale. In oil firing the scale produced is soft and loose whereas in the ordinary gas forge it is hard and sticky and acts as an abrasive on the dies. Soft scale gives about double the die life. Figures are given showing detailed savings. The amount of scale formed depends upon the time of exposure, the temperature and the furnace atmosphere whereas the type of scale is determined entirely by atmosphere. To obtain a fast heating rate, the heat transfer may be obtained best by the flame itself rather than from a high thermal head. Therefore a luminous flame is essential. An atmosphere of 2-3% CO does not prevent scaling; it merely decreases the rate. To prevent scaling the reducing gases must be 4 times as great as the oxidizing. If reducing gases are CO and hydrocarbons, the steel will carburize, thus lowering the melting point and causing pitting. The less scale formed, the smoother the finished forging. Steels containing less than 1% C can be safely heated to a higher temperature in a reducing atmosphere than in an oxidizing atmosphere. Work leading to the development of "diffusion flame combustion" furnaces by the Surface Combustion Corp. is described. In this type the inter-diffusion of gas and air which issue from the burner in separate layers mix the gases at a slow rate. The hydrocarbons crack into H and free C which, heated to incandescence, is the source of luminosity which is equal to that of an oil flame. An emissivity factor as high as 0.6 has been secured. The rate of heat transfer is proportional to emissivity, thus permitting rapid heating with low temperature differential. The burner and furnace are designed to obtain a parallel flow of reacting gases. This makes it possible to provide a raw duct so that the steel while being heated is blanketed in raw gas thus making it possible to produce a forging practically scale free. Preliminary tests show a heating rate of at least 150 lbs./ft.^{2} of hearth/hr. as against 100-120 lbs. in oil fired furnaces. RJC (23)

Furnaces for Burning Blast-Furnace Gas. Otto De Lorenzi. *Blast Furnace & Steel Plant,* Vol. 19, Jan. 1931, pages 135-139, 142.

Burner design, furnace design, preheating of air and firing methods in furnaces for burning blast-furnace gas are described. The change from other gas-heated furnaces consisted in inverting the furnace and firing from the bottom instead of from the top. Experiences with 3 installations which have given good results are given. Ha (23)

Steel Furnace Repairs. Walter Lister. *Metallurgia,* Vol. 5, Nov. 1931, pages 17-18 and 28.

Detailed directions for repairing the port ends of open-hearth furnaces are given. JLG (23)

Gas in Industry (Das Gas in Gewerbe und Industrie). H. Lent. *Gas und Wasserfach,* Vol. 74, Sept. 19, 1931, pages 873-877; Sept. 26, 1931, pages 905-908.

The speaker at the 72nd General Meeting of the Deutscher Verein von Gas- und Wasserfachleuten, June 1931, Breslau, is particularly concerned with the great advances of gas firing as a coming competitor of electric heat in industry. Attention is focussed upon the characteristics and the advantages of both kinds of heat applied to industrial furnaces. Stress is laid on the difficulties met in the utilization of electricity at temperatures higher than 1300° C. After a general discussion of the subject, the author takes up the various types of gas-fired furnaces all of which, except one, belong to the metallurgical industry. The features of the different furnaces of German design are discussed at length and abundantly illustrated. EF (23)

Rules for Comparing the Economy of Purification Plants of Blast Furnace Gas. (Richtlinien für den Wirtschaftlichkeits-Vergleich von Hochofengas-Reinigungsanlagen.) F. Lüth. *Archiv für Eisenhüttenwesen,* Vol. 5, Nov. 1931, pages 223-230.

Report 123 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. 9 references. Descriptions are given of gas purification by wet, dry, and electro-cleaning, which are about equally effective. By the last 2, a gas of 60°-80° C. can be obtained, containing 60-150 g./m.^{3} of vapor. With an additional cooler, they can furnish also a saturated gas of 20°-30° C. corresponding to the wet cleaning process. The individual parts of the various methods and the necessary conversion to attain a common basis of comparison are discussed. The comparative total cost of purification for wet, dry and electro-cleaning was respectively 0.7623, 0.5029, and 0.3213 marks/1000 m.^{3} of dry gas during the month of comparison, and 0.2728, 0.2681 and 0.3001 at 100% utilization. GN (23)

Transformers for Electric Furnaces. (Les Transformateurs pour Fours Electriques). M. G. Marty. *Journal du four electrique,* Vol. 39, Oct. 1930, pages 378-380, 415.

See *Metals & Alloys,* Vol. 2, Jan. 1931, page 16. (23)

Electric Heating Furnaces Find Place in Steel Mills. A. H. Vaughan. *Steel,* Vol. 89, July 30, 1931, pages 34-36.

Car type, pit type and continuous furnaces for annealing, normalizing and heat treating are described briefly. Ha (23)

The Present Status in the Construction of Resistance Furnaces for Industrial Purposes. (Die gegenwärtige Lage im Bau von Widerstandsofen für industrielle Zweecke.) V. Paschkis. *Elektrotechnische Zeitschrift,* Vol. 53, Jan. 14, 1932, pages 25-27; Jan. 21, 1931, pages 58-62, 66-70.

The materials used in resistance furnaces up to 1500° C., their shapes and the construction of units and the assembly of units as used in modern furnaces are discussed, charging devices are described and sources of heat losses and their magnitude are discussed. Ha (23)

REFRACTORIES & FURNACE MATERIALS (24)

Refractories. F. H. Norton. McGraw-Hill Book Company, New York, 1931. Cloth, 6 x 9½ inches, 594 pages. Price $6.00.

The author is Assistant Professor of Ceramics, Massachusetts Institute of Technology, and in addition to his teaching has done a large amount of research and development work in the refractories field. In this volume a complete, detailed, and concise description is given of refractories from the occurrence of raw materials to the testing of the finished product. Sufficient information is given of each department of refractories manufacture to give the student a complete picture of the subject. In addition the large selected bibliographies at the end of each chapter provide an easy method for the student to secure further and more detailed information.

The metallurgist will find of particular value the chapter on the measurement of high temperatures and the sections describing the factors that influence load bearing capacity, spalling, and slagging of refractories and the methods for measuring them.

Two chapters are devoted to a discussion of the use of the microscope and the X-ray in the study of refractories. Although space did not permit the author to make these chapters exhaustive, they give an excellent introduction to these subjects and point to future possible developments in these methods of study.

This volume provides a complete and up-to-date publication on refractories which should prove to be extremely useful to both the producer and the user of refractories.

C. E. Williams (24)-B-

Investigations of the Reversible Heat Expansion of Refractories (Untersuchungen über die umkehrbare Wärmeausdehnung feuerfester Steine). A. Kanz. *Stahl und Eisen*, Vol. 52, Jan. 7, 1932, pages 18-19; *Mitteilungen Forschungs Institut der Vereinigten Stahlwerke*, Vol. 2, 1931, Report No. 5, pages 77-96.

Refractories either expand or contract during burning, but the coefficient of heat expansion can be made reversible either by repeated burning or by burning at sufficiently high temperatures. The investigation method of Steinhoff & Nopitsch (*Tonindustrie Zeitung*, Vol. 51, 1927, pages 918- 920, 1011-1013, 1047-1049) was used to measure the reversible heat expansion of 10 different fire-clay bricks, 15 silica bricks, 2 samples of quartz slate, 12 samples of magnesite bricks, 32 samples of special refractory bricks and 32 samples of artificially made quartz free clay. The limit values of the mean linear coefficient of heat expansion are given in the table below. The coefficient depends largely on the temperature, but for most of the materials tested, it increased linearly with the temperature. An exception to this rule are the bricks containing free silica. With fire clay bricks containing quartz and silica bricks, faulty burning causes considerable variations of the coefficient of heat expansion, as well as a difference in behavior between case and core of the bricks. Silica bricks show a relation between specific gravity and coefficient of heat expansion.

Material	Mean linear coefficient of heat expansion between 200° and 1000° C.
Fire clay bricks	5.54- 6.81 $\times 10^{-6}$
Quartz fire clay bricks	4.99- 6.29 $\times 10^{-6}$
Quartz free fire clay bricks (own make)	4.40- 5.09 $\times 10^{-6}$
Silica bricks	12.72-15.41 $\times 10^{-6}$
Quartz slate brick	18.29-18.65 $\times 10^{-6}$ (1st test)
Quartz slate brick	10.09 $\times 10^{-6}$ (2nd test)
Magnesite bricks	13.74-14.53 $\times 10^{-6}$
Magnesia mass	13.86-14.48 $\times 10^{-6}$
Chromite bricks	7.27- 9.08 $\times 10^{-6}$
Bauxite bricks	5.19- 6.51 $\times 10^{-6}$
Corundum bricks	5.58- 7.03 $\times 10^{-6}$
Sillimanite bricks	4.95 $\times 10^{-6}$
Zirconium bricks	5.01- 5.66 $\times 10^{-6}$
Carborundum bricks	4.37- 5.42 $\times 10^{-6}$

GN (24)

Relative Heat Transfer Through Refractories. A. S. Watts & R. M. King. *Engineering Experiment Station Bulletin* No. 64, *Ohio State University*, 1931, 32 pages.

The methods by which heat is transferred and the laws governing these methods are reviewed; the mathematical expressions for the determination of heat conductivities of refractory materials are discussed. The samples consisted of 9" straights, 2.5" thick, and 9" splits, 1.25" thick of a great number of chemically different materials and were tested at hot face temperature of 800° and 1000° C. The method permitted an accuracy of 10%. It can be stated that the surface greatly influences the heat-transfer; many factors affecting the heat transfer have seldom been taken into consideration, which accounts for unreliable values of commercially fabricated pieces. Heat transfer can be only roughly correlated with chemical composition and physical properties of the pure crystal, but other factors such as porosity, surface effects and the heterogeneity of the mass must be considered. The factors to be considered are: 1. the technique of measurement, 2. the physical properties of the pure crystal, 3. the surface properties of the test piece, 4. the porosity of the test piece. In an appendix the test method used is critically analyzed, and a list of 81 bibliographical references is added.

Ha (24)

Manufacture of Refractories Tends Toward Uniformity. H. M. Kraner. (Westinghouse Elec. & Mfg. Co.) *Steel*, Vol. 88, Jan. 22, 1931, page 47.

Minor developments in the refractory industry for 1930 include definite improvements in size and shape control of clay refractories and a greater degree of uniformity in quality and methods of manufacture. Satisfactory bonding materials have been achieved for use with zircon and magnesia furnace linings and superior patching materials have been developed from a study of the system, $CaO-MgO-Fe_2O_3$.

JN (24)

Refractories in Metallurgical Operations. Clyde E. Williams. (Battelle Memorial Institute) *Metals & Alloys*, Vol. 3, Jan. 1932, pages 3-11.

22 references are cited. As over ⅓ of the refractory brick used in industry go into open-hearth furnaces the refractory problems in this furnace have been subject to extensive studies. The necessity for high mechanical strength require silica brick for the roof. Causes of failure due to spalling with temperature changes and slagging action of the oxide particles carried in the gases are discussed. The improvement of the life of roof brick by use of thicker brick and by insulation are discussed. Normal life is about 300 heats which is capable of considerable increase to over 600 by application of thicker roof, combustion control and insulation. The lack of satisfactory mechanical properties in neutral and basic brick requires judicious arrangement for their use in side walls. The cutting action of the acid slag dripping from the roof also must be considered. Building up a sloping back wall of bottom material in the basic furnace has advantages. Silica brick in ports are protected from corrosion by oxide particles by covering of magnesite or chrome cements. High-alumina clay refractories have been used satisfactorily in water cooled ports. The problem of slagging and clogging action in checker work is discussed and the properties required of the firebrick used for this application. In the acid open hearth furnace the corrosive action and slagging of the bottom with iron oxide offers the chief difference from the basic bottom. Resistance to metal penetration and chemical attack by molten metal and slag of high FeO content is necessary in ladle linings which are briefly discussed. The large quantity of refractory necessary to make a blast furnace lining even tho it lasts for several years of continuous operation makes the selection of refractories important. The qualities of fire-brick for this use vary with the severity of service encountered in the zones of the furnace, hearth, bosh, shaft, and top. Special problems in refractories for heating furnaces, cupolas, copper smelters, air furnace, arc and induction furnaces are similar to those met in the open hearth and are briefly discussed under these headings. The temperature conditions are usually less severe except in the case of steel melting in arc and induction furnaces.

GASES IN METALS (25)

The Heat of Absorption of Hydrogen by Palladium Black at 0°. Louis J. Gillespie & Henry A. Ambrose. *Journal of Physical Chemistry*, Vol. 35, Nov. 1931, pages 3105-3110.

The authors have measured the loss of energy attending the absorption of H by Pd black, using an ice calorimeter. The loss of heat content found for the reaction $H_2 + 4\ Pd = 2\ Pd_2H$, where Pd_2H gives the average composition of the 2 solid phases formed, is 9280 cal_{15}.

On the Correct Experimental Method for Establishing the Independence of the Hydrogen Content and the Hardness of Electrolytic Iron (Sur la méthode expérimentale propre a établir l'indépendance de la teneur en hydrogene et de la dureté du fer électrolytique). Guichard, Clausmann, Billon & Lanthony. *Comptes Rendus*, Vol. 193, Nov. 31, 1931, pages 1084-1085.

A further contribution to the discussion of this problem, the authors criticizing the experiments that had been carried out by Guillet, Roux and Cournot (*Comptes Rendus*, 1931, Vol. 193, page 685). See following abstract.

OWE (25)

New Observations Relative to the Influence of Occluded Gases on the Mechanical Properties of Metallurgical Products (Nouvelles remarques relatives á l'influence des gaz occlus sur les propriétés mécaniques des produits métallurgiques). Leon Guillet, Albert Roux & Jean Cournot. *Comptes Rendus*, Vol. 193, Oct. 26, 1931, pages 685-687.

A further contribution to the discussion of the controversial question of the relationship between the hardness of electrolytic metals, and iron in particular, and their hydrogen content. The authors support the view that this hardness is a function of the hydrogen content of the material, while Guichard and his collaborators believe it to be a function of the grain size of the material. The experiments which the authors describe, involving the extraction of hydrogen from samples of cathode iron by treatment in vacuo at various temperatures, lead them to a repetition of their former view that it is impossible to establish the fact that the hardness of electrolytic iron is entirely independent of the hydrogen content.

Effect of Hydrogen Sulphide on Wire Rope. L. W. Vollmer & B. B. Wescott (Gulf Research Labs.) *Transactions American Society Mechanical Engineers*, PET 52-7, Oct. 1930, pages 39-45.

The embrittlement of wire rope used in drilling oil wells in fields where H_2S is present, was forcefully brought out by experience in the West Texas field where the gas contains 15% H_2S. The fractures were intercrystalline, and showed strong similarity to those due to H embrittlement from pickling. Likewise, the degree of embrittlement declined on standing. A hard drawn 0.7% C wire exposed to moist H_2S, would stand only 30% as many revolutions at a certain stress in a rotary bending test of the type used by Langdon and Grossman (*Transactions American Electrochemical Society*, Vol. 37 (1920) page 543) as would the unexposed wire, i.e., it was 70% embrittled. On standing for a day, the embrittlement declined to 13%, and in a week, to 6%. Gentle baking (400° F. for 3 hours) will practically remove the trouble. The maximum attainable degree of embrittlement in hard drawn steel increased with the degree of cold work, and was not related to C content. On long exposure, a protective film was formed and recovery, i.e., diffusion out of H, outran damage, i.e., taking up of H. In annealed wire, Armco iron was more embrittled (80%) than high C, and the maximum degree of embrittlement in the other wires was fairly constant at from 25 to 45%, irrespective of C content. The embrittlement was ascribed to adsorbed atomic H. It was concluded that the adsorption of atomic H increases as the purity of the ferrite increases. The intergranular ferrite in the high C steels is considered purer than in ingot iron. Prevention of contact between H_2S and the rope, by galvanizing, by lead or copper coating, or to some degree, by lubrication of the rope, is advised. Tin is worthless as a protective coating.

Nitrogen in Mild Steel. *Metallurgist*, Apr. 1931, pages 51-53.
A review of the work of Köster in *Archiv für das Eisenhüttenwesen*, Vol. 4, Dec. 1930, pages 289-294. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 152. VVK (25)

Hydrogenized Iron. P. P. Cioffi. *Bell Laboratories Record*, Vol. 10, Jan. 1932, pages 159-163.
Iron heated in hydrogen at 1400°-1500° C. for 18 hrs. and subsequently annealed below 910° C. produces iron with a maximum permeability of 140,000, or 18 times that of ordinary annealed iron. The maxima do not occur at the same value of magnetizing force. At 0.04 gauss, the permeability is 500 times, and initial permeability is 20 to 50 times that of ordinary iron. The hysteresis loss at a flux density of less than 200 ergs/cm.^{3}/cycle, is 1/16 that of ordinary iron, and is but 1/3 that of permalloy. Water vapor must be present in the hydrogen. Carbon is removed in the hydrogen treatment, and about one atom of hydrogen to 1000 atoms of iron is retained, but the exact mechanism of the action is in doubt. Ha + HWG (25)

Oxides in Aluminum. *American Metal Market*, Vol. 38, Aug. 13, 1931, pages 4, 10.
. Reprinted from bulletin of International Smelting Co. Certain effects such as cores in castings, excessive shrinkage, low fluidity, high surface tension and poor machinability indirectly serve as causes for the presence of oxides in aluminum. Proper smelting procedure will produce metal with low oxide effects, either with material first produced from oxide ores or secondary aluminum. Strict control of melting temperatures, proper use of the right fluxes and use of certain highly specialized process will give the lowest heat control. Effect of high oxides may be produced in the foundry by overheating the metal, by improper addition of gates and sprues, by bad melting practice and by churning air into the metal while it is being poured. The paper points out: (1) that there is no satisfactory direct method of determining fine oxides in aluminum and (2) that statements regarding oxides in aluminum should be carefully weighed because the trouble may not be oxides after all. DTR (25)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

On the Influence of the Alloying Elements Nickel, Silicon, Aluminum and Phosphorus on the Solubility of Carbon in Liquid and Solid Iron (Ueber den Einfluss der Legierungselemente Nickel, Silizium, Aluminium und Phosphor auf die Löslichkeit des Kohlenstoffs im flüssigen und festen Eisen). E. Söhnchen & E. Piwowarsky. *Archiv für Eisenhüttenwesen*, Vol. 5, Aug. 1931, pages 111-121.
In melting electrolytic iron in a Tammann furnace and carburizing it by sugar carbon and Acheson graphite, a preliminary alloy of about 4.27% C, 0.05% Mn, 0.025% P, 0.024% S and traces of Si was made; by adding ferrosilicon (98%) cube nickel, technical aluminum and ferrophosphorus (23%), alloys were obtained which were cast into bars, 20 mm. in diameter in sand molds. With these bars the effect of the above elements upon structure, total C content, graphite content and Brinell hardness was studied. Further experiments were carried on to establish quantitatively the effect of Al upon the C solubility in liquid state. Up to Al content of 3%, Al displaces C more effectively than does Si but, above 3%, Si is more effective. By means of a quenching method in vacuum, the solubility of C in Fe as well as this solubility in the presence of Ni, Si, Al, Si and Ni together and Si and P together was studied. The results on the quenching tests of the pure Fe-C alloys are tabulated below and indicate, in comparison with investigations of other authors, that the graphite solubility line takes its course at higher C contents than has previously been assumed.

Temperature °C	Total carbon content %	Graphite content %	Combined-carbon content %
800	4.25	3.19	1.06
	4.40	3.41	.99
900	4.84	3.54	1.30
	4.78	3.55	1.23
1000	4.28	2.80	1.48
	4.10	2.58	1.42
1100	4.38	2.54	1.84

The displacement of C by the above alloying elements decreases in the following order: P, Si, Ni. No reliable results as to this point could be obtained with Al, probably because of the oxidation of this element, since it could be verified by analysis that a large amount of the Al added did not go into solution but remained as Al_2O_3. Phosphorus contents up to 0.5% do not affect the C solubility. The results of the quenching tests of the samples containing up to 2% Si and 4% Ni show that the C-displacing effect of these 2 elements is governed by an additive law. GN (27)

Alloy Cast Iron. *Metallurgist*, Oct. 1931, pages 156-157.
An extended abstract of a bulletin on "The Development and Present Position of Nickel Cast Iron in Engineering Practice" issued by the Bureau of Information on Nickel. Ni may be alloyed with cast iron in all proportions. Like Si, it promotes graphitization and, therefore, prevents thin sections from becoming chilled and consequently too hard to machine; at the same time, it does not lower the hardness or tensile strength of the thicker sections. The effect of Cr in cast iron is to stabilize the carbide, thus producing an increased tendency to chill. In this respect, therefore, Cr is unlike Ni, although both elements combine to give uniformly increased hardness and resistance to impact and wear. In order to obtain a completely martensitic cast iron, either 6 or 7% of Ni or the equivalent in Ni and Cr may be added or a lesser amount of these elements followed by an oil or air hardening treatment. Under certain conditions, the presence of even small quantities of Ni and Cr may improve the heat and corrosion-resisting properties of gray or white cast iron; whereas, if added in larger quantities, thus rendering the iron austenitic, the improvement in these properties is most marked. 6% Si will confer increased resistance to oxidation at high temperatures while a larger amount will render it almost immune to attack by acids. Mo, V and Ti appear to strengthen cast iron and to exercise a refining action upon the graphite. VVK (27)

Useful Properties are Afforded by Manganese Steel. D. H. Young (Amer. Manganese Steel Co.). *Steel*, Vol. 88, Feb. 19, 1931, pages 51-52.
Abstract of a paper read before the National Western Metal Congress, San Francisco, Feb. 16-20, 1931. JN (27)

The Influence of Various Additions on the Properties of Gray Cast Iron. (Einfluss verschiedener Sonderbestandteile auf die Eigenschaften des Graugusses.) *Die Metallbörse*, Vol. 21, Feb. 21, 1931, pages 340-341.
36 references. The influence of the following elements on gray cast iron is summed up: Cu, Pb, Mg, Mo, Bi, B, Ca, Ce, Sb, As, Co, V, Zn, Zr, Sn, Ti, W, U. EF (27)

Effects of Small Amounts of Copper, Nickel, and Cobalt on the Oxidation Reactions of Iron. (Einfluss kleiner Mengen von Kupfer, Nickel und Kobalt auf die Oxydationsvorgänge beim Eisen.) Hubert Kirscht. *Stahl und Eisen*, Vol. 52, Jan. 21, 1932, page 71; Doctor's thesis, University of Münster, 1931, 28 pages.
After reviewing work author points out that Fe forms an endless series of mixed crystals with Ni and Co, but this is not the case with Cu. Increasing amounts of Cu, Ni, and Co were added to Fe, the non-ferrous metals being prepared from their oxides by reduction with H. After complete removal of H, which required heating at least 10 days in vacuum, at 900° C., measured amounts Co_2 were added. Equilibrium condition was allowed to take 3 to 6 days and resulting gas mixture analyzed. The solubility of O in the Fe is thus given and the O pressure of the oxidized Fe may be calculated. Addition of Cu, Ni and Co decreases solubility of O in Fe and also causes a rise in O pressure. O solubility in pure Fe at 800° C. is 0.5%, while with alloys it is 0.05%; alloys of Cu, containing 0.5% Cu, showed maximum effects, the O pressure decreasing with increasing Cu content. The following table shows effect of additions to oxygen pressure of oxidized iron.

	Addition	%	Temp. °C.	Composition of Gases of Reaction % CO_2	% CO	Relative O Pressure, referred to Pure Fe as 1.000

INSTRUMENTS & CONTROLLERS (28)

Fundamentals of Instrumentation. M. F. Behar. Instruments Publishing Company, Pittsburgh, 1932. Cloth 6 x 9¼ inches, 109 pages. Price $2.00.
This introductory book, though Part One of the author's "Manual of Instrumentation," is self-contained. It opens with a preface presenting in an inimitable manner the value of control in industry through the use of instruments *i. e.*, "instrumentation." He predicts "the early recognition of Instrumentation as a distinct branch of engineering, and as a distinct field of scientific management." The line of development is outlined as first such re-design of one apparatus or another as to make such and such a condition measurable—and then controllable.
The book presents the definitions of the various terms, and classifications of the fields of use of instruments, and of the instruments themselves. It describes the various elements that compose instruments, and discusses the possibilities of accuracy of the measurements by various means, and deals with the performance of the more complicated instruments by the use of which control of various conditions may be secured.
The reviewer extends a most hearty welcome to this book, the first attempt that he has seen to bring in a complete form, into one volume, an understandable presentation of the fundamentals of measurement and control, herein called instrumentation. He will make one excerpt only from the preface, hoping thereby best to present the appeal of the present volume: "The production man, whatever be his official title and whatever branch of engineering he may practice, is the one for whose particular benefit these handbooks are written. It had to be so, for the main purpose of industrial instruments is to aid production, to subserve the application of efficiency principles, 'highest quality at lowest production cost,' and the other maxims of scientific management."
A brief résumé of the contents best illustrates the scope of this book as a guide to better solution of production problems through measurement and control. Chapter I, on Industrial Instruments, contains such subheads as "Classification (of Instruments) by Function," and "Principal Parts of Industrial Instruments." Chapter II treats of "Properties and Characteristics of Industrial Instruments." "Performance of Controllers" is the subject of Chapter III, and Chapter IV is a symposium on "The Plant Instrument Department."
In conclusion, it seems to the reviewer that this book might well have been named "The Philosophy and Fundamentals of Instrumentation." It puts into practical form the author's philosophy "that the outstanding characteristic of industrial instruments is that they yield tangible and practical dividends," thereby presenting to the busy production man the fundamental information about instruments in a way that makes it readily available and easily understandable. S. L. Goodale (28)-B-

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Non-Ferrous Alloys. Part I. Copper, Brass, Bronze, Red Brass (Nichteisen Metalle). R. HINZMANN. No. 45 of Simon's Werkstattbücher. Julius Springer Verlag, Berlin, 1931. 56 pages. Price 2 RM.

Condensed information as to properties of these alloys. Most of the data are elsewhere available, though here collected in handy form. Some data on short-time tensile tests at high temperatures are included, as follows: Tensile strength is in lbs./in.^{2}, elongation, % in two inches.

It is stated that Cu-Mn alloy with 5 to 6% Mn, of 45,500 to 51,000 lbs./in.^{2} tensile, 85 Brinell, 35 to 39% elongation, used for staybolts, does not lose strength till the temperature is over 300° C. H. W. Gillett (29)-B-

The Plasticity of Metals. ZAY JEFFRIES. *Scientific Monthly,* Vol. 33, Sept. 1931, pages 235-243.

Plasticity is the quality by virtue of which a substance may undergo a permanent change in shape without rupture. In many non-metallic plastic materials the flow is essentially fluid. During the deformation the solid particles move bodily and the liquid conforms to the new shape. The mechanism of the plastic deformation of metals is quite different. Metals are crystalline and plastic flow is the result of block movement of one portion of the crystal with reference to another, the movement being along crystallographic planes. Since hardness is measured by resistance to plastic deformation, and methods or treatments designed to change hardness constitute a large part of the metal art, plasticity assumes a major role on the metallurgical stage. The study of the plastic deformation of single crystals of various metals and X-ray crystal analysis have greatly enriched our knowledge in the past 15 years. Realizing the extreme softness of single crystals of metals and the very slight changes in hardness with change in temperature, at least within certain temperature limits, it seems remarkable that the mere aggregation of differently oriented single crystals can result in the properties offered by poly-crystalline metals. A Mo wire composed of a series of single crystals had the same strength (30,000 lbs./in.^{2}) in the temperature range 100°-900° C., whereas a finegrained Mo wire had its strength reduced from 115,000 lbs./in.^{2} when tested at 100° C. to 70,000 lbs./in.^{2} at 900° C. A single crystal of W can be bent at room temperature, but in liquid air the elastic limit is enormously increased and fracture occurs without any noticeable deformation. Coarse-grained Mo more than trebles its tensile strength under similar conditions. Face-centered cubic metals retain their plasticity at liquid air temperatures. In general the body-centered cubic metals do not retain their plasticity at low temperatures as well as face-centered metals. Hexagonal rhombohedral metals like Bi and Sb become very brittle at temperatures not far below their freezing points. Fine-grained and coarse-grained commercial wrought Zn at liquid air temperature shows no plasticity. A single crystal of Mg, however, shows considerable plasticity at -190° C. Again Be becomes non-plastic well below room temperature. The author urges upon physicists the potentiality of the study of plastic deformation in metals as a means of unlocking some doorways to nature's secrets of the internal structure and properties of solids. WAT (29)

New Uses for Bolts Demand Higher Standards of Manufacture. F. O. KICHLINE. *Steel,* Vol. 89, Oct. 26, 1931, pages 31-33, 38.

Bolts for railroads and high-pressure purposes are now made of special steels, one a low carbon Ni-Cr, the other a Cr-W; analysis and treatment are described in detail, physical tests made extended also to creep tests over 1000 hours at 1000° F. The characteristics are tabulated. Ha (29)

Heat-Resisting Alloys. J. FERDINAND KAYSER. *Foundry Trade Journal,* Vol. 45, Dec. 31, 1931, pages 412, 414.

After dealing with the properties required in heat-resisting alloys, the author deals with the subjects of oxidizing and reducing atmospheres, respectively, pointing out that reducing atmospheres containing sulphur dioxide and hydrogen sulphide are the most dangerous with which heat-resisting alloys have to contend. Some attention is given to the phenomenon of creep and to the effects of repeated heating and cooling on heat-resisting alloys. The history of the evolution of heat-resisting alloys is dealt with briefly, the article closing with a description of recent heat-resisting cast irons. OWE (29)

The Scaling and Corrosion of Steel for Steam Boilers and Superheaters. *Quarterly of the British Electrical and Allied Industries Research Association,* Feb. 20, 1931, J/E/T 14, pages 13-23.

With O-free steam the corrosion due to the rate of reaction between steam and steel superheaters is negligible for steam temperatures up to 427° C. and tube temperatures up to 510° C. In the absence of free O, scaling is definitely lessened by the use of fuel low in H. The use of Enduro KA2 superheater tubes with temperatures on the fire side up to 650° C. is not limited by the reaction between Fe and steam. H gas evolution is accelerated by O entering the system with the feed water. Within limits the alkalinity of the boiler water will have no noticeable effect on the rate of reaction between Fe and steam. A definitely alkaline boiler water and feed water is preferred to prevent corrosion and limit corrosion due to other conditions. However, alkaline water does not stop corrosion due to O. Free C in a smoky atmosphere has a negligible effect in preventing scale formation. Caustic embrittlement is retarded by the presence of sodium sulphate and the action is dependent on the sulphate concentration. Chromate in small concentration has a similar effect but there is a consumption of chromate owing to the oxidation of H. The embrittling effect of magnesium chloride at 310° C. is diminished by the addition of sodium sulphate or potassium chromate. The value of electro-deposited coatings of metals such as Ni and Cr as preventatives of corrosion is of interest as no practical applications of this nature are recorded, in boiler practice, at the present time. The thickness of the plated metal and the particular metal to be used in a particular service is of extreme importance. WAT (29)

Thermal Expansion of Heat Resisting Alloys: Nickel-Chromium, Iron-Chromium, and Nickel-Chromium-Iron Alloys. PETER HIDNERT. *Bureau of Standards Journal of Research,* Vol. 7, Dec. 1931, pages 1031-1066; *Bureau of Standards Research Paper* No. 388.

This paper gives data on the linear thermal expansion of various heat resisting alloys (Ni-Cr, Fe-Cr and Ni-Cr-Fe). The alloys contain 0-77% Ni, 5-27% Cr and 0-82% Fe. The coefficients of expansion of the alloys were determined for various temperature ranges between 20° and 1000° C., and the effects due to temperature, chemical composition, heat treatment, etc., were determined. Critical regions were located on the thermal expansion curves of some of the alloys. For a given temperature range, the coefficients of expansion of Ni-Cr alloys containing from 0 to about 20% Cr are nearly the same. The effects of Cr content, C content, heat treatment, etc., on the coefficients of expansion of Fe-Cr alloys for various temperature ranges are indicated in a single figure. The results on the thermal expansion of Ni-Cr-Fe alloys were correlated with the structure of the alloys. Transformations from one phase to another caused significant changes in thermal expansion. The expansion curves on the first heating of nearly all of the cast Ni-Cr-Fe alloys indicated a retardation or decrease in expansion between 700° and 800° C., due to precipitation of the carbide. The effects of change of composition on the coefficients of expansion of both cast and annealed Ni-Cr-Fe alloys are indicated. The table gives a comparison of the expansion of the 3 groups of alloys.

	Chemical Composition		
Alloys	Ni	Cr	Fe
Group 1 Ni-Cr	76.8-77.0%	19.3-20.4%	
Group 2 Fe-Cr		17.0-24.6%	74.0-81.7%
Group 3 Ni-Cr-Fe	1.3-70.1%	4.9-26.7%	6.6-74.7%

High-Temperature Creep Properties of Wrought Carbon and Low-Alloy Steels. A. P. Spooner (Bethlehem Steel Company) & F. B. Foley (The Midvale Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 368-393.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 193. In discussion data are given from the U. S. Bureau of Standards on short-time tensile tests and Charpy impact tests on two rail steels (1) 0.69% C, 0.70% Mn and (2) 0.59% C, 1.30% Mn. These data are from a study of the blue brittleness or secondary brittleness known to exist in steels in the neighborhood of 300° C. In discussion from the Crane Company it is stated that, while it is now generally admitted that at temperatures where creep is a factor, no true elastic limit is determinable for the purpose of design, nevertheless, there is a temperature range, up to 600° F., for heat-treated alloy steels, in which short-time test data are quite as valid as at ordinary temperatures. It is in the temperature range above 700° F. that delicate extensometers start to show uncertain proportional limit values, and where creep data begin to be at variance with short-time tensile values. It is also suggested (International Nickel Company) that more attention be given to structural stability of metals at elevated temperatures. The aging effects (decrease in notch toughness and ductility, increase in hardness, and changes in rate of chemical attack) initiated by cold work are important in parts which are fabricated prior to elevated temperature service. Data taken from the work of Pomp and Bayer indicate that steels containing Ni do not show as great a tendency toward aging embrittlement or grain growth as do plain C steels. Several three-dimensional diagrams illustrate this feature. From the University of Michigan are data indicating that the proportional limit does correctly portray the creep characteristics corresponding to 1% flow in 100,000 hours within a definite temperature range. This temperature range is generally just below the lowest temperature of recrystallization, or the equi-cohesive temperature of the given alloy. If the given temperature is too far below the lowest recrystallization temperature, then strain hardening may occur and the creep strength is considerably above that indicated by the proportional limit. If the given temperature is too far above the lowest recrystallization temperature, then, under long periods of time, the deformation occurs around the crystals rather than in them and the results indicated by the proportional limit are too high. The data presented indicate that short-time or accelerated creep tests do not give an accurate indication of the actual creep characteristics of a metal. High C steels are superior to low C steels in their ability to withstand the continued application of stress, at least to 850° F. These conclusions are based on both short time tensile and creep tests. The thought of a number of other discussions, however, is that the C content is not the only factor in plain C steels controlling the elevated temperature strength. The other usual elements present and the process of manufacture are also equally as important as the carbon content. Tabulated data from the General Electric Company show the stresses producing a flow rate of 1% in 100,000 hours, between 400° and 550° C. for 12 C and alloy steels. In the authors' closure it is emphasized that a satisfactory short-time method for determining elevated temperature properties of metals is still needed. WAT (29)

Engineering Requirements and Trends for Metals in the Ferrous Metal Industries. J. C. Woodson (Westinghouse Electric & Manufacturing Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 112-150.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 193. In the discussion it is pointed out that imperfect castings have probably been the greatest single cause of trouble in the service of cast furnace parts. The major portion of the discussion does not agree with the author that the problem of growth, expansion, warping and cracking is more severe with cast resistors than with the malleable or wrought elements. In high temperature work the casting of the same composition (except possibly higher carbon) will keep its shape better and be freer from warpage, than the rolled material, especially as for the same cost it will be thicker than the same composition fabricated in rolled form. Intricate shapes may be cast, while to fabricate the same shape by any other method would require welding. Despite the great progress made in welding it is still the weakest link in the chain. Another discusser also stresses the point that more research should be done on welded materials at elevated temperatures. It is further emphasized that great care should be used in defining the operating conditions to which a given material will be subjected. The use of nitrided boxes, using a 25% Cr and 20% Ni alloy, is reported as giving satisfactory service in Germany. WAT (29)

Stayrods and Firebox Plates. R. Kühnel. *Metallurgia,* Vol. 5, Dec. 1931, pages 53-56.

Translation of an article in *Zeitschrift für Metallkunde,* Vol. 23, Jan. 1931, pages 1-11. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 283. JLG (29)

The Strength at High Temperatures of a Cast and a Forged Steel as used for Turbine Construction. H. J. Tapsell & A. E. Johnson. *National Physical Laboratory, London, Engineering Research, Special Report,* No. 17, 1931, 33 pages.

The report contains the results of short-time tensile tests and creep tests carried out on a 0.30% C cast steel and a 0.39% C forged steel over a temperature range of approximately 400° to 650° C. Full tensile properties and the stresses corresponding to rates of creep down to 10^{-5} in./in./day have been determined. The results are given in numerous tables and curves. They show that the cast steel possesses limiting creep stresses of 10, 8, and 4 tons/in.^{2} at 400°, 450°, and 497° C. respectively while the forged steel has the values of 13, 10, and 5 tons/in.^{2} at 400°, 447°, 507° C. respectively. Ha (29)

Some Observations on the Dilation of Several Common Steels. H. E. Publow, C. M. Heath & M. E. Batchelor. *Michigan State College Engineering Experiment Station Bulletin* No. 41, Dec. 1931, 15 pages, 12 figures.

Elementary discussion of the use of the Chevenard dilatometer. Unannealed specimens from the same bars of steel gave discordant results. Carburized 0.15% C steels with 1½% Ni, ¼% Mo; 3½% Ni and 5% Ni gave less permanent shrinkage than a carburized 0.05% C plain carbon steel. A plain carbon carburized specimen 2.160" long heated past the critical 21 times, then measured 2.135". The amount lost by scaling is not stated. The decrease on each heating varied from 0.0004" to 0.0010". Ha + HWG (29)

Metallurgical Requirements for High-Temperature Steam Piping. F. W. Martin (Sargent & Lundy). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 49-65.

For abstract of paper see *Metals & Alloys,* Vol. 2, Oct. 1931, page 232. In the discussion it was stated that stresses at high temperatures producing 2 or 3% deformation in rigid portions of piping systems may produce dangerous stress combinations. It is suggested that seizing of screwed connections may be minimized by nitriding the nuts and using the differential pitch idea to avoid concentrating the load on the first few threads. The use of materials of differing thermal expansion in nut and stud may also help. An alloy containing 48.9% Ni, 29.5 Co, 8.4 Fe, 9.5 Cr, 2.4 Ti, 0.5 Al and Si, 0.2 Mn and C is recommended by Westinghouse Electric & Manufacturing Company as being a worthwhile steam piping material. At 1100° F. this material has a proportional limit of 57,500 lbs./in.^{2}, a Johnson limit of 71,300, 0.2% yield point 86,000, 0.5% yield point 85,000, tensile strength 127,000, elastic modulus 26,000,000, elongation and reduction about 20%. The Detroit Edison Company reports relatively small changes in the physical properties of 18-8 Cr-Ni steel after 6400 hours in piping operating at 700° - 1100° F. The material is subject to strain hardening, and there is a change in its microstructure due to migration of carbides to the grain boundaries. The material, however, is still quite ductile and tough, and shows resistance to sulphur attack. WAT (29)

The Mechanical Properties of Aluminum and Magnesium Alloys at Elevated Temperatures. R. L. Templin & D. A. Paul (Aluminum Company of America). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 290-315.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 193. In the discussion additional data are presented by the Dow Chemical Co. on three cast Mg-base alloys, containing (1) 8.1% Al, 0.2% Mn, (2) 1.92% Mn and (3) 3.8% Al, 0.34 Mn, and also on two extruded Mg-base alloys containing (1) 8.19% Al, 1.27 Cd, 2.02 Cu, 0.34 Mn, 0.47 Zn, and (2) 1.92% Mn. Short-time tensile strength values are given for these five alloys between 20° and 450° C. A brief comparison is made between a number of Mg alloys and some of the more widely used Al alloys reported in the original paper. A great similarity exists between the curves showing the effect of elevated temperatures on the tensile properties of Al and Mg alloys. Both wrought Al and wrought Mg alloys are more susceptible than the cast alloys to changes produced by elevated temperatures. The Al alloys as a class possess somewhat better tensile properties than do the Mg alloys in the temperature range of approximately 300 - 600° F. The differences in tensile properties at room temperature and at moderately elevated temperatures, due to alloy composition, heat treatment and mechanical working, largely disappear as the temperature is still further raised, so that at temperatures between 700° and 800° F. all alloys, both those of Al and Mg, irrespective of prior treatment, possess approximately the same tensile strength. WAT (29)

REDUCTION METALLURGY (31)

Present Smelter Practice—Calumet and Hecla Consolidated Copper Company. Endicott R. Lovell & Herman C. Kenny (Calumet & Hecla). *Mining Congress Journal,* Vol. 17, Oct. 1931, pages 533-538.

The entire metal content of the Calumet & Hecla concentrates is native Cu except for the Cu oxide from the ammonia leaching. Cu is too low in Ag to warrant electrolytic refining; it contains no Au whatever, and other impurities, principally As, are removed by fire refining only. From the concentrates a rich mixture, 75% Cu and a low-grade one of 40% Cu, both self-fluxing, are made. About 5% coal or coke screenings is added to each of the above mixtures, and 8% is added to CuO leached material. Smelting operation consists of (1) melting, (2) refining, and (3) casting into refined shapes. Melting is done in pulverized coal-fired reverberatory furnaces, centercharged through openings in the arch. During the melting period, the furnace atmosphere is kept slightly reducing and together with coal screenings, prevents loss of oxidized Cu in the slag. Melting furnace Cu runs 98.7% Cu, 1.0% Fe, 0.20% S, and 0.04% As. The slag runs 42.5% SiO_2, 30% FeO, 13% Al_2O_3, 8% CaO, 2.3% MgO and 0.60% Cu. Average daily melting furnace capacity is 280 tons of concentrates, 120 tons of slag and 75 tons of coal. Fe is removed in refining by throwing sand over the bath to flux Fe oxide as it is liberated. Fluid slag is skimmed off. The As is removed by blowing in from the bottom powdered soda ash and perhaps some added lime. Soda slags are very corrosive to brickwork and linings and need to be removed immediately as formed. The poling period then begins. High volatile bituminous coal with 4.5% ash and S always below 1.0% is burned. Prime Calumet & Hecla Cu analysis: Cu and Ag, 99.95%, As 0.0025%, Fe 0.0025%, Ni 0.0015, S 0.0015 and O_2 0.042%. Diagrammatic sketches of smelter and refining furnaces are shown. Melting costs per ton of concentrates are $2.80; refining costs per ton of Cu, $2.91; casting costs, $1.07 per ton of Cu. DTR (31)

Refining of Nickel According to the Orford Process. (Die Raffinade von Nickel nach dem Orfordverfahren.) THEWS. *Die Metallbörse,* Vol. 21, Sept. 5, 1931, pages 1674-1675.

The Orford process, developed by the Orford Copper Co., is based on the separation of Cu-Ni sulphides into layers when fused with Na_2S. The present operation of the process at Port Colburn, Ontario, by the International Nickel Co. is described. EF (31)

Manufacture of Chrome-Iron Alloys—"Wild" Direct Reduction Process. *Foundry Trade Journal,* Vol. 46, Feb. 11, 1932, pages 101-103.

The works of the Darlington Rustless Steel & Iron Co. are described. The process developed by Ronald Wild, of Sheffield, for the production of Cr-Fe alloys involves the direct reduction of Cr ores. The output is remarkably high, even from the viewpoint of regular steel-making practice. Details are given of the types of rustless Fe that are produced by the process. OWE (31)

Handling of Non-Ferrous Flue Dust. (Zur Behandlung des metallhüttenmännischen Flugstaubes.) THEWS. *Die Metallbörse,* Vol. 21, Aug. 15, 1931, page 1541.

Briquetting and sintering of flue dust in non-ferrous plants. EF (31)

The Treatment of White Metal Waste and Drosses. (Zur Behandlung metallischer Weissmetallkrätzen und Abzüge.) E. R. THEWS. *Die Metallbörse,* Vol. 21, Aug. 1, 1931, pages 1443-1444.

The different metallurgical methods in relation to the composition of the delivered white metal wastes and drosses are reviewed. EF (31)

Development of Gun-feed Reverberatory Furnaces at Garfield Plant of American Smelting & Refining Co. R. A. WAGSTAFF (American Smelting & Refining Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 471, Feb. 1932, 7 pages.

Finely ground, hot calcines were charged in matte furnace below the moving gas stream of the combustion zone using the gun feed. This decreased dust losses and increased furnace life over charging through the top. JLG (31)

Sintering Zinc Ore at Rosita, Mexico. H. R. MACMICHAEL (American Smelting & Refining Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 455, Feb. 1932, 8 pages.

A sintering plant that successfully handles 9,000 tons of preroasted finely ground flotation concentrates per month is described. The charge contains from 5 to 9% S, and the sinter 0.5%. JLG (31)

The Recent Development of the Coley Process. (Die moderne Entwicklung des Coley Verfahrens.) O. W. ROSKILL. *Die Metallbörse,* Vol. 21, Aug. 27, 1931, pages 1587-1588; Aug. 29, 1931, page 1637.

The latest advances of the Coley process for the production of Zn in a continuously working drum furnace, are given and experiences gain on 2 plant installations are presented. EF (31)

The System $PbO-Sb_2O_3$ and Its Relation to Lead Softening. C. G. MAIER & W. B. HINCKE (U. S. Bureau of Mines). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 449, Feb. 1932, 12 pages.

Equilibria in the system $PbO-Sb_2O_3$ were studied by thermal analyses, vapor pressure measurements and microscopic examinations. A compound, $PbO \cdot Sb_2O_3$, is formed. With increasing PbO the vapor pressure decreases until it becomes very small at 40% PbO (535° and 697° C.), thereby indicating that crystals of free Sb_2O_3 were present up to this concentration of PbO. The effects of oxidation and reduction are discussed, as well as the practical applications of the conclusions. 4 references. JLG (31)

Molybdenum Bronzes. (Zur Kenntnis der Molybdänbronzen.) W. G. BURGERS & J. A. M. VAN LIEMPT. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 202, Dec. 24, 1931, pages 325-328.

The electrolytic reduction of acid molybdate melts produces, according to the composition of the baths, a reddish-brown MoO_2 or Mo-blue. The formation of so-called Mo bronzes could not be detected. Ha (31)

The Use of Limestone in the Iron and Steel Industry. Part III. OLIVER BOWLES (U. S. Bureau of Mines). *Rolling Mill Journal,* Vol. 5, Apr. 1931, pages 247-250.

A knowledge of the occurrence, properties, and methods of quarrying and treating limestone is of value to the furnace operator in selecting a source of supply. The impurities found in a given limestone may be inherent in the rock and impossible of separation by the quarryman or they may be present merely as sand or clay and readily eliminated by careful quarrying. Various considerations such as available CaO, increased fuel cost, decreased furnace output, comparative transportation costs, etc., must be balanced in deciding on a cheaper impure CaO. Other necessary considerations are uniformity in composition of successive shipments, MgO content not exceeding 5%, and the absence of excessive amounts of impurities in the fines. JN (31)

Healthful Smelting Conditions Promote Efficiency. R. P. E. HERMSDORF & R. WINTERS. *Engineering & Mining Journal,* Vol. 132, Apr. 1932, pages 197-200.

The new Pb plant of the United States Metals Refining Co. at Carteret, N. J., is an example of thoughtful design and careful planning to eliminate hazards formerly considered unavoidable. All furnaces discharge into an elaborate, balanced flue system. 4 separate ventilating systems are installed to reduce fumes: (1) for the reverberatory furnace and launder, (2) for softening furnaces and utility furnace, (3) for blast furnace, and (4) for retorts. Employes are under strict medical supervision and examination. WHB (31)

Reverberatory Smelting of Raw Concentrates at the International Smelter, Miami, Arizona. P. D. I. HONEYMAN (International Smelting Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 456, Feb. 1932, 11 pages.

Very fine flotation concentrates containing 11% water are being fed directly to the reverberatory. The costs for wet smelting on a reduced schedule compare favorably with the costs of prior practice at capacity production where the concentrates were dried, and the dust nuisance is practically eliminated. With a wet charge furnace wear is reduced, and the waste heat can be utilized. The changes in furnace charging and operation necessary for successful wet smelting are described. JLG (31)

Studies of Magnetic Sands. I. Factors Affecting the Rate of Reduction of Titaniferous Magnetic Sands. II. Effect of Silicious Matter on the Reduction of Magnetic Sand. III. On the Roasting of Magnetic Sand and Its Subsequent Reduction. KEIZO IWASE, MASAJI FUKUSIMA, MASAMI KOBAYASI & SHINROKU MITSUKURI. *Science Reports of the Tohoku Imperial University,* Japan, Vol. 20, Oct. 1931, pages 489-521, 522-535, 536-559.

Experiments carried out with 3 kinds of magnetic sands occurring in Japan have shown that they are much less reducible at temperatures between 800° and 1050° C. than hematite and magnetite. The grain size of the sand and the reducing agent have a great effect on the efficiency of the reduction. The content of TiO_2 in the sands varies from 0.5 to 42%. The test results are given in tables and diagrams. Part II. The presence of silicious matter generally retards the reduction rate of magnetic sands at 1000° C. or higher. When the sands contain reducible hematite excellent sintering occurs which is not the case with magnetite, which is reducible with difficulty up to 1050° C. By taking a longer period of time it is possible to reach 100% reduction even in the presence of silicious matter. Between 1000° and 1050° C., 100% reduction is reached in 2½ hrs. if the amount of silicious matter is made as small as possible. Part III. The sands were roasted at 700°-1100° C. in air and then reduced. It was more difficult to oxidize the sands completely to the ferric state than to deoxidize them completely to the metallic state because the roasting consists of only 1 stage of reaction, namely oxidation, while reduction consists of 2 stages of reaction taking place in succession, i.e. deoxidation and carburization. The size of the sand has a greater influence on the degree of oxidation than on the degree of reduction. In general, the poorer the reducing conditions the greater the advantage of roasting, but this may be modified by the temperature of reduction, nature of reducing agent and material to be reduced. Ha (31)

Blast Furnace Efficiency. S. P. KINNEY (H. A. Brassert Co.). *Blast Furnace & Steel Plant,* Vol. 19, Dec. 1931, pages 1562-1565.

Present practice is compared with that of 1924. Larger hearth diameter has been followed by an increase in the diameter of the stockline. The Venturi throat is a simple and efficient means of increasing stockline diameter and reducing dust losses. The Eichenberg process for reduction of flue dust has been widely adopted in Europe. This method consists of forming a rotating screen or curtain of gas and water at right angles to the upward flow of the gas. This screen is formed just above the stockline by using tangential jets of gas and water. Use of stockline recorders, showing movement of the stock column, enables the operator to correct conditions to obtain uniform furnace operation. Recently developed, electrically operated, automatic mud gun provides means of stopping the hole without taking off the blast, thus preventing undue settlement of the stock. Heat balances are presented for (1) 14 American furnaces operating on Mesabi practice in 1924 and (2) modern furnaces, practice being practically the same, except that whereas blast temperatures were formerly 1000°-1200° F., common practice now utilizes 1500°-1600° F., thus increasing the heat supplied to the furnace. This is accomplished by the use of fine cleaned gas on small checkered high-efficiency stoves employing the principle of uniform velocity and turbulent flow. Heat balance shows that of the total heat accounted for in the shaft, 89% may be accounted for now as compared with 81% in 1924, and that 53% is now used for reduction of the oxides as compared with 46% formerly. An increase of about 30% in the efficiency of boilers using blast furnace gas has been attained by better methods of heat transfer and the use of gas which has been previously cleaned. MS (31)

The Electrochemistry of Rhenium. A Few Reduction Products Originating at the Electrolysis of aqueous Potassium-Perrhenate-Solutions. (Beiträge zur Elektrochemie des Rheniums. Ueber einige Reduktionsprodukte, die bei der Elektrolyse von wässrigen Kaliumperrhenatelösungen entstehen.) H. HOELEMANN. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 202, Dec. 24, 1931, pages 277-291.

The methods for the reduction of ageous K-perrhenate solutions are reviewed and the qualitative phenomena of these electrolytic reductions described with and without the addition of H_2SO_4 or Na_2CO_3. The reduction products were investigated; the deposit on Pt cathodes contained oxide. Ha (31)

The Messina Stationary Basic Copper Converter. R. G. KNICKERBOCKER. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 458, Feb. 1932, 11 pages.

The smelting furnace at Messina, South Africa, produced a high-grade matte containing 60% Cu and practically no Au or Ag. The plant was constructed for production by the Nicholls-James process, but did not operate satisfactorily. Three furnaces had been built in cascade so that the molten matte or Cu could flow from one to the other. The second furnace was converted into a stationary converter. Tuyeres with oil-cooled steel pipe plugs were installed in this furnace. Details of construction of tuyeres and plugs are given. The matte was blown successfully to blister Cu in this furnace and refined in the third furnace. Cu meeting the A.S.T.M. specifications could be produced by this process, and the costs compared favorably with large scale production by other methods. JLG (31)

Flash-Combustion Roasting of Iron Pyrites. HORACE S. FREEMAN. *Transactions American Institute of Chemical Engineers,* Vol. 26, 1931, pages 148-157; *Chemical & Metallurgical Engineering,* Vol. 38, June 1931, pages 334-336.

From many mixed sulphide ores flotation has made available Fe pyrite ground to 200 mesh and even finer, containing 50% S and a minimum amount of gangue. When this product is roasted in the mechanical types of roasters at present in use it is found that, on account of the rapid roasting of the fine material and the greater amount of heat generated, the capacity of the roaster is considerably decreased and the wear and tear on brickwork and rabbles, and the cost of roasting are correspondingly increased. A special roaster was designed to overcome these difficulties. The engineering factors involved are discussed and the plant is described. The resultant product is interesting as a raw material for the production of sponge-Fe, to be directly smelted in electric furnaces. WHB (31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Relation of Coefficient of Expansion to Cross-Bending Strength of Sheet-Steel Enamels. MURRAY C. GAUTSCH. *Journal American Ceramic Society,* Vol. 15, Jan. 1932, pages 8-12.

2 series of enamels were made with calculated cubical coefficients of expansion from 361 to 306. In both series of enamels, the cross-bending values were inversely proportional to the coefficients of expansion. This is due to the fact that all enamels on sheet steel have lower coefficients of thermal expansion than steel. In cooling, after the enamel is fused to the metal, strains are set up in the enamel that lower the expansion of the enamel the greater the strains. When the enameled piece is bent, the greater the stresses present, the farther the piece can be bent before there is any real tensile strain on the enamel. High bending ability is dependent primarily on high compressive strains induced by lower coefficient of expansion of the enamel than the metal base. Compressive strains cause warping, fish-scaling (in ground coat), and chipping; therefore, the bending strength should not be too high. In all control work, both the minimum and the maximum bending strength should be specified. WAT (32)

Acid-Resisting, Dry-Process, Cast-Iron Enamels, and the Effects of BaO, PbO, and ZnO. L. D. FETTEROLF. *Journal American Ceramic Society,* Vol. 15, Jan. 1932, pages 1-7.

The following composition is suggested as one to which an acid-resisting enamel should agree in many respects:

	Per Cent		Per Cent
Na_2O	18	SiO_2	42
Ba_2O_3	5	Sb_2O_3	10
CaO	4	BaO	
CaF_2	1	PbO	14
TiO_2	6	ZnO	
			100

86% of the enamel composition must be held within these limits. This composition containing 14% ZnO or PbO, or any combination of these, smelts satisfactorily. Enamels containing 5% or more of BaO have poor smelting properties. Considering acid resistance, the amount of ZnO permissible depends upon the criterion used. The 7% citric acid test would permit up to 8% ZnO. The 7% HCl test would permit about 6% ZnO. The latter percentage agrees with the ZnO content of satisfactory enamels developed by Andrews. BaO and PbO are about equal and have no adverse effect on acid resistance. ZnO and PbO produce better gloss than BaO. Color and brightness may be improved by substitution of ZnO and (or) BaO, but preferably ZnO, for PbO. ZnO and BaO have about equal effects on fusibility. The fluxing effect of PbO is more pronounced. The proper combination of ZnO, BaO, and PbO must be determined by consideration of the acid resistance, fusibility, color and brightness requirements of an enamel. Each appears to contribute desirable properties. A desirable balance of these constituents in an enamel appears to be approximately 5% ZnO, 2% BaO, and 7% PbO. WAT (32)

Synthetic Resins Cut Finishing Time, Protect Longer. JOSEPH GESCHELIN. *Automotive Industries,* Vol. 65, Dec. 1931, pages 950-955, 958.

Author describes new resin surface with unique film-forming properties. This new surface can be introduced into present automobile body operations with reduction in baking period. Illustrations show (1) results of some representative hardness tests; (2) character of adherence and flexibility of film; (3) time process charts with 2 methods of finishing. The existing commercial synthetic resins are of 3 classes: (1) nitrocellulose lacquers, (2) varnishes, (3) condensation finishes of the air-dry and low-bake type; advantages of these finishes are enumerated. DTR (32)

Soil Action on Pipe Line Coatings. GORDON N. SCOTT (Bureau of Standards). *Gas Age-Record,* Vol. 65, Apr. 12, 1930, pages 510, 513-514.

Paper before the American Gas Association Distribution Conference, St. Louis, Apr. 1930. The action of the soil on protective coatings causing disruption of the coating, the so-called "soil-stress" effect, is described and explained. VVK (32)

Concrete Coverings for Pipe Lines. J. F. HOUGH (Portland Cement Association). *Oil & Gas Journal,* Vol. 29, Jan. 15, 1931, pages 62, 140-141.

As the result of testing some 2,000 concrete cylinders 10" in diameter and 24" long in sulphate soils and waters at Montrose, Colo., and Medicine Lake, S. D., the following coating and procedure was recommended for protecting pipe lines from soil corrosion. A mixture consisting of 1 part Portland cement, 1½ parts well-graded sand (0 to ¼") and 3 parts of gravel (¼" to ⅝") made with 4¾ gallons of water per sack of cement is poured into a sheet metal form around the pipe and shaken down with an electric vibrator. Reinforcement such as welded wire 2" x 6", No. 12 by No. 12, improved the strength of the coating. If reinforcement is not used, an asphalt emulsion is first applied to the pipe. The concrete covering should be at least 1" thick. Examples of pipe lines coated with concrete in extremely corrosive soils which have shown entirely satisfactory protection are given. VVK (32)

The Economics of Protective Coatings. LE ROY SLOAN (Southern Counties Gas Co.) & R. U. FITTING (Los Angeles Gas & Electric Corp.). *Gas Age-Record,* Vol. 66, Sept. 13, 1930, pages 405-406, 410.

Paper presented before the Pacific Coast Gas Association, Sept. 1930. Formulae and curves are given for estimating the allowable amount to be spent to justify a protective coating for a pipe line. VVK (32)

Synthetic Resins Provide Durable, Colorful Enamels for Metal Products. GEORGE S. HERRICK. *Iron Age,* Vol. 128, Dec. 10, 1931, pages 1482-1483, 1534.

The demand for colorful and durable finishes is broadening into new fields of metal consumption and the adoption of rustless steels has increased for colorful enamels on ordinary steel. Due to elasticity and toughness available in resins, enamel manufacturers are producing a variety of baked and air drying finishes. VSP (32)

Black Spots in Enamels. *Glashütte,* Vol. 61, 1931, pages 868-870.

Black spots in white enamels are usually caused by the presence of impurities or by chemical conversions of these impurities in the enamel. They may be produced by dust from the drying operation or during enameling, or by small particles of rust from the metallic frames used in the drying installations. The mills may also cause these spots and great care should be taken during their cleaning. The enamel should be fused in covered crucibles so that light ashes and soot will not fall into the melt. Chemical reasons for the black spots are: (1) They may appear if Sn oxide is used as opacifier when it contains large quantities of metallic Sn. Sn oxide should not contain more than 0.1% metallic Sn. (2) The enamel should be fired in a pure oxidizing flame, otherwise a reduction of Sn oxide to stannous oxide occurs producing the black spots. To avoid this reduction, the enamel batch should contain at least 6% saltpeter which counteracts the reduction in the melt and in the muffle. (3) Sb oxide being very easily reduced may cause black spots which also may be prevented by additions of saltpeter. (4) The black spots may be caused by the metal of the object and by the ground glaze. If the sheet metal contains accumulations of C and is not thoroughly pickled, this C promotes reduction. Small bubbles are formed which later collapse but leave in their place the black spots. If the coating of the ground enamel is irregular and covers the places containing C very thinly or not at all, C reacts more strongly. A ground enamel with good covering power and containing sufficient borax and bonding oxides should be used. WAT (32)

Formation of Wrinkles in Porcelain Enamel. *Glashütte,* Vol. 61, 1931, pages 832-833.

2 kinds of enamel should be used for enameling bathtubs because the vaulted edges of the tubes have greater tensions than the flat sides of the tubs. The enamel used for the edge should have a higher expansion than that used for the sides, a difference of 10 to 20 points depending upon the quality of the Fe. During enameling both enamels are mixed to a certain extent and a silky luster, which consists of very fine waves, appears in the place where the enamels were mixed. The explanation for this phenomenon is given. If the assumption that the formation of fine waves is due to the formation of a solid "skin" on the surface which wrinkles, then the size of the wrinkles depends on the size of contraction (shrinkage) of the enamel. In order to regulate the shrinkage, it is necessary to know the expansion of the enamel in the temperature field where it changes from the liquid to the solid state. The "crystallization" of the enamel is another important moment. Enamels oversaturated with opacifiers tend to crystallize and precipitate the opacifier at a definite temperature and a silky luster and mat enamel results. An enamel which is not oversaturated with opacifiers and whose coefficient of expansion at the critical temperature is known will shrink the least within the "skin" and therefore show the smallest waves. Microscopical researches show the exact reactions taking place between the 2 powder enamels. Both enamels endeavor mutually to decompose during firing which is impossible, owing to the short time at firing temperature. The greater the difference in the softening of the melting points between the edge and the interior powder, the more intensive is the reaction, and the more mat the enamel appears in this place. The melting points of both enamels should therefore be as close as possible because the greater this difference is, the more mat the enamel will be. WAT (32)

A. P. I. Pipe Coating Tests: Progress Reports to The American Petroleum Institute Committee on Corrosion of Oil Field Equipment. GORDON N. SCOTT (A. P. I. Research Associate, Bureau ofStandards). *Proceedings American Petroleum Institute,* Dec. 1931, Section IV, pages 53-107.

Progress Report No. 1—Installation of Test Coatings. The A. P. I. pipe coating test is a nationwide coöperative investigation of pipe protective coatings involving the pipe line interests, manufacturers of protective coatings, and the U. S Bureau of Standards. Tests are being made in 16 locations on 46 coatings applied to short lengths of pipe and on 19 coatings applied to working oil lines, 6" to 10" in diameter. The coatings are both mill-applied and field-applied. The test sites are distributed throughout the country, and represent a variety of soil and climate conditions. Complete details of installation are given. Progress Report No. II—Initial Inspection of Specimens. In addition to the visual examination of the specimens, two practicable tests for the field examination of protective coatings have been developed and described in detail. The conductance or resistivity of the coating was determined by first painting the coated pipe with flowing mud, wrapping with crepe paper and then applying a pad previously soaked in salt water, electrical contact then made with the pipe and the conductance determined by the voltmeter-ammeter method. After the conductance determination was made, a battery was connected, the pipe made the anode and current allowed to pass for from three to six minutes. The pad was then removed, the paper peeled off, immersed in 1% to 2% potassium ferricyanide made slightly acid with vinegar, washed and dried. This "pattern test" gave a record of the pinholes, flaws, etc. in the coating. The data to date indicates definitely that the effectiveness of the coating increases very rapidly with the thickness up to about 0.20". Comparatively thin asphalt and coal tar coatings were ineffective but the heavy coatings of both types were effective. Enamel coatings without shields or reinforcements reduce the anticipated average pitting by roughly 50% or less. All of the fabric-reinforced treatments, excepting a reinforced grease coating, reduce the anticipated average pitting by 80% or more. Shields are effective in general, but wood veneer is less effective than strip steel or pipe line felts. The problem of perfect protection is still largely one of minimizing the effect of soil stress. VVK (32)

Cement Lining of Used Cast Iron Pipe. J. R. TANNER. *Journal American Water Works Association,* Vol. 23, Apr. 1931, pages 521-528.

An account of the salvaging of a 16" water line; its cleaning and lining with cement. VVK (32)

ORE CONCENTRATION (33)

Refractoriness. H. A. White. *Journal of the Chemical Metallurgical, & Mining Society of South Africa,* Vol. 32, Dec. 1931, pages 97-101.
A mathematical measure of the refractoriness of an ore, especially the banket of the Witwatersrand, is developed.

The flow sheet of the Daggafontein Au mill is described.
AHE (33)

The Relations Between Colloid Chemistry and Concentration. (Die Beziehungen zwischen Kolloidschemie und Aufbereitung.) W. Petersen (Bergakademie Freiberg). *Die Metallbörse,* Vol. 21, July 4, 1931, pages 1251-1252; July 11, 1931, pages 1299-1300; July 18, 1931, pages 1347-1348; July 25, 1931, page 1397.
Surface phenomena as the essential feature of the new concentration methods, colloid mills, dispersoid analysis, methods based on surface tension, flotation, oil sand dressing, electro-osmosis, kaolin elutriation, handling of waste water and differential sedimentation are discussed. EF (33)

Flotation (33c)

Use of Flotation in the Separation of Gold-Bearing Minerals. (El Empleo De La Flotation Para El Tratamiento De Las Minerales Auriferos). *Revista Minera,* Vol. 82, Dec. 1931, page 550.
Abstract of article originally published in *Anales de Minas de Rumania,* May and June, 1931. From the point of view of flotation, Au-bearing minerals may be classified as follows: (1) minerals that contain native Au with quartzose gangue; (2) those in which Au is combined with pyrite or other sulphates; (3) those that contain Au with appreciable amounts of As, Te, or Sb; (4) Cu, Pb, Zn, etc., minerals, in which Au is present as an impurity. These types of ore should be treated as follows: (1) flotation, followed by direct smelting of concentrates; (2) flotation, followed by amalgamation or cyanidation of concentrates; (3) amalgamation or cyanidation followed by flotation; (4) flotation followed by cyanidation of tailings. No flotation data are given.
DTR (33c)

Sodium Diethyldithiophosphate (Soda Aerofloat) as a Flotation Reagent. L. M. Becker. *Tzvetnuie Metallui,* Aug. 1931, pages 984-989.
American and Russian Na aerofloats gave unsatisfactory results in floating oxidized ores of Cu but gave very good results on sulphide ores. BND (33c)

Selective Flotation of Lead-Tin Oxide Ores in Mexico. (Auswählende Schwimmaufbereitung oxydischer Blei-Zinnerze in Mexiko.) C. Bruchhold. *Metal und Erz,* Vol. 28, Dec. 1931, pages 541-545.
In the Santa Eulalia plant of the American Smelting and Refining Co. in Chihuahua, Pb-Sn oxide ore is successfully concentrated by selective flotation. The very finely ground ore is treated with Na_2S and a concentrate of $PbCO_3$ is separated. The remaining Sn and Fe_3O_4 are smelted and separated electro-magnetically. The newest Fahrenwald flotation machine is described. CEM (33c)

Milling Methods and Costs at the Verde Central Concentrator, Jerome, Ariz. R. H. Dickson & E. M. Smith. *United States Bureau of Mines Information Circular* No. 6489, Sept. 1931, 12 pages.
The ore, which is composed of quartz, pyrite and chalcopyrite, averages Cu 2.7%, Ag 0.4 oz./ton and a negligible amount of Au. By flotation, recoveries of 93.3% of Cu are obtained in a concentrate assaying Cu 19.83%, Fe 28.9% and insoluble 16.1%. Tailings assay Cu 0.20%. Total costs are $1.192/ton of ore milled. AHE (33c)

Flotation. A. M. Gaudin. McGraw-Hill Book Co., New York, 1932. Cloth, 6 x 9½ inches, 552 pages. Price $6.00.
This book on flotation, the first in English since Taggart's in 1921, has been eagerly awaited by the metallurgists, chemists, college students, and business men for whom it was written. Great strides have been taken in the art since 1921, and few men in this country, or in the world, are as well qualified to describe and interpret them for us as Gaudin, whose work on the flotation of pure minerals has given him an international reputation. He outlines his book as follows: historical; fundamental chemistry; general technology; detailed technology and practice; economics. The development of the theory of flotation is especially clear, logical and complete, but perhaps does not indicate sufficiently the unstable character of many of the details of the theory, some of which are at present in controversy. Due to lack of space, crushing and grinding phases of the process are not considered, and little attention is devoted to mill design and flotation machinery; the historical and legal aspects also receive only brief treatment, owing, as Gaudin remarks, to signs of the patent tangle being cleared up. The book must inevitably be compared with the two recent German books on the subject, by Luyken and Bierbrauer and by Mayer and Schranz. Gaudin's exposition of the theory is more careful, and as his book is concerned chiefly with American practice, will be of more use to the American. It, like the other two, indicates the scope of modern flotation, which is now undertaking, experimentally and commercially, the concentration of a wide variety of sulphide and oxidized ores and non-metallic minerals.
John G. Attwood (33c)-B-

Flotation of Gold and Silver Ores. *Chemical Engineering & Mining Review,* Vol. 24, Feb. 5, 1932, pages 169-174.
From the standpoint of flotation, Au and Ag ores may be divided into 6 major groups: (1) ores containing native Au in quartz or quartz-adularia gangue; (2) ores with Au and Ag associated with oxides of Pb, Cu, and Fe; (3) ores with Au and Ag associated with pyrite or other sulphide; (4) ores with Au and Ag associated with As, Sb, or Te; (5) Co-Ni-As ores containing native Ag, and (6) ores with the Au and Ag associated with sulphide minerals of Cu, Pb, and Zn. General schemes utilizing flotation include: (1) straight flotation, followed by smelting of the concentrate, (2) flotation and amalgamation, (3) flotation followed by amalgamation and/ or cyanidation of the concentrate, and (4) flotation followed by cyanidation of the flotation tailings. Examples of these are cited. It is concluded that flotation is an accessory to cyanidation and that probably the combination of the 2 methods will extend the use of both, with flotation applied as a preliminary concentration treatment to raise the grade of the feed to the cyanide plant.
WHB (33c)

The Influence of Temperature on Flotation. (Ueber den Einfluss der Temperatur auf die Flotation.) Ion Huber-Panu. *Metall und Erz,* Vol. 28, Dec. 1931, pages 545-549.
The rate of flotation increased with rising temperature in every case studied. At 40° C. the time required was only ½ that at 6°. The foam going over in the first minute contained 50 to 100% more ore at the optimum temperature than at 6°. During succeeding minutes the ore content was lower with rising temperature. The total yield increases with rising temperature to a maximum and then drops off. Each ore has an optimum temperature, usually between 23° and 40°. The magnitude of the temperature effect depends on the flotation reagent, it is greater with xanthate and T-T mixture than with wood tar oil. In Cu ore the highest separation at 35° was 73% greater than the highest separation at 7°.
CEM (33c)

Pyrite Flotation at Aldermac, Quebec. W. G. Hubler (Aldermac Mines, Ltd.). *Canadian Mining & Metallurgical Bulletin* No. 239, Mar. 1932, pages 82-91.
Flotation reagents for the treatment of the old ore dump were: (1) Cu circuit: ball mill — lime 6-8, NaCN 0.01-0.05, thiocarbanalide 0.15 and xanthate 0.10; flotation pump sumps-pine oil 0.10; primary cells — $CuSO_4$ 0.15 lb.; (2) pyrite circuit: agitator cell — $CuSO_4$ 0.54, xanthate 0.25; cell 6 — xanthate 0.10 lb. When milling mine ore the reagents used were:—(1) Cu circuit: ball mill — soda ash 2.0, cyanide 0.04, thiocarbanalide 0.09; classifier overflow pump sump — pine oil 0.04; Cu roughers — pine oil 0.05, Na ethyl xanthate 0.05; (2) pyrite circuit: agitator cell — $CuSO_4$ 0.25, Na ethyl xanthate 0.17; cells 4, 6, 8, and 10 — xanthate, to each cell, 0.04; cell 6 — water gas tar 0.15 lb. The pyrite is suitable for flash roasting. AHE (33c)

Flotation Reagents, 1929. T. H. Miller & R. L. Kidd. *Report of Investigations* No. 3112, *United States Bureau of Mines,* Aug. 1931, 20 pages.
The total consumption of reagents in lbs./ton of ore treated in 1929 decreased over 4% from 1928. Trends: decreased consumption of frothing reagents, substitution of synthetic collectors for distillation collectors, more extensive use of butyl and amyl xanthates, introduction of aliphatic dithiophosphates and more extensive use of alkaline circuits. Pine oil, cresylic acid or o-toludine (frothers) was used in treating 98.44% of the ores floated. Consumption was 0.144 lb./ton of ore. Coal-tar creosotes, coal tars, wood-tar creosotes, pine-tar oils, petroleum products, blast-furnace oils, water-gas tars, ethyl xanthates (most important), butyl xanthates, amyl xanthates, dicresoldithiophosphoric acid, Na discresoldithiophosphates, Na diethyldithiophosphate, other dithiophosphates, benzyl mercaptan, thiocarbanilide and a-naphthalamine (all collectors) are used at the average rate of 0.126 lb./ton. H_2SO_4, 22.03 lbs./ton, and 3.735 lbs. of Na_2CO_3, NaOH, CaO (most important) or cement per ton are used to regulate the pH of the circuit. Na_2S is used for sulphidizing; $CuSO_4$ for activating; cyanides, Na_2SO_3, Na silicate, $ZnSO_4$ and Na_3PO_4 (average 0.213 lb./ton) for depressing; and $Al_2(SO_4)_3$, $CaCl_2$, NaCl, Na_2SO_4, S, turpentine and linseed oil for miscellaneous purposes. The use of each reagent on different ores is shown tabularly.

The Iron Losses in Magnetic Separation. I. (Om järnförlusterna vid magnetisk separation.) Ernst Rothelius. *Jernkontorets Annaler,* Vol. 116, Jan. 1932, pages 1-19.
Studies have been carried out on the magnetite losses in 4 mills using both magnetic separation and concentrating tables. In mill A, in which 2 magnetic separators in series were adjusted to take a constant amperage of 6.5 and 5.6, the larger particles of magnetite were not taken out by the separators, and the smaller ones were washed away on the concentrating table. The magnetite losses are not given, but it is recommended that the ore be screened in two portions, one above 0.208 mm. and the other below, and these parts treated separately with the proper amperages and H_2O currents. Below 0.208 mm. the individual ore particles were cleanly broken. In mill B, 4 magnetic separators were used in series with 5 amp. at 104 volt and 35 r.p.m. The smallest particles were not adequately extracted, but were satisfactorily recovered by tabling. In mill C, 2 magnetic separators were used in series with 10.5 and 5 amps. at 110 volts and 35 r.p..m. In mill D, the same arrangement was used with 9.5 amp. at 104 volts and 43 r.p.m. The total recoveries of magnetite were, respectively, 86%, 88.2% and 94.3% on B, C, and D. Further laboratory studies are under way. HCD (33d)

MANUFACTURERS' LITERATURE REVIEWS

392 **Eraydo**—A pocket-size booklet prepared by the Illinois Zinc Co., Chicago, Ill., describes their new alloy, Eraydo. It is a zinc base alloy containing silver and copper. It is a tough metal, well adapted to deep drawing, extruding and forging. The booklet contains several chapters showing the many advantages of Eraydo in manufacturing operations. It is fully illustrated.

393 **Furnace Pressure Control**—Ryan, Scully & Co., Philadelphia, Pa., have prepared their Bulletin No. 1 in the form of a leaflet which describes their system of automatic pressure control in heat treating and heating operations.

394 **Industrial Compounds**—Technical Products Co., Pittsburgh, Pa., have issued Insa-Lute Cement & Compounds Catalog No. 32 which contains instructive information on industrial assembling, insulating, acid-proofing, etc. It gives many applications of their compounds for surface coating, furnace sealing, fireproof painting, electric insulation, repairing, etc.

395 **Cast Iron Pipe**—The United States Pipe and Foundry Co., Burlington, N. J., presents the new edition of the "Handbook of deLavaud Centrifugally Cast Iron Pipe." It gives the standard specifications for their cast iron pipe and tables showing the dimension and weights of the various classes.

396 **Table of Conversion Factors**—The Dorr Co., Inc., 247 Park Ave., New York, has prepared a table of conversion factors for engineers, a compendium of useful data for the rapid conversion of the common engineering units of measure of one system into the related units of another system.

397 **Cadmium Plating**—The Grasselli Chemical Co., Cleveland, Ohio, has sent out an attractive leaflet entitled "The Key to Lowest Possible Plating Costs" which describes the advantages of their Cadalyte process for electro-depositing pure metallic cadmium on iron and steel. With this process the plating time is said to be reduced and the equipment to cost less.

398 **Sand Core Binder**—General Plastics, Inc., North Tonawanda, N. Y., has prepared a leaflet telling about their Durez 476, a new and different binder for sand cores. It is used just as any oil is used and is recommended especially for cores of complicated design.

399 **Nickel Steel Topics**—The International Nickel Co., New York, N. Y., has issued Vol. 1, No. 1, of a new bi-monthly publication which contains technical, semi-technical and news articles dealing with the production, treatment and uses of nickel alloy steels.

400 **Magnetic Analysis**—Catalog No. 4 of the Magnetic Analysis Corp., 42 Twelfth St., Long Island City, N. Y., is a 20-page pamphlet which gives the theory of magnetic analysis, a description of the apparatus used and the properties of magnetic steel which have been determined with this equipment. Oscillograms are shown which were obtained in its application to strip steel, tool steel, butt welded tubing and the separation of steels of different chemical analysis.

401 **Corrosion-resisting Alloy Steels**—A 4-page bulletin giving physical and chemical data on these steels has been issued by the Duriron Co., Inc., Dayton, Ohio. A table of resistance to various chemicals for Durimet, KA2S and KA2SMo is included. There are also notes on machining, heat-treating and welding. This is bulletin No. 171.

ALPHABETICAL INDEX TO ADVERTISERS

◆ ◆ ◆

402 **Electric Furnaces**—The Pittsburgh Electric Furnace Corp., Pittsburgh, Pa., has distributed a folder containing a description of one of the company's furnaces which is in operation at the Beach Foundry, Ltd., giving complete operating data and costs.

403 **Welded Construction**—Bulletin No. 2 of Lukenweld, Inc., Coatesville, Pa., contains many pictures showing the extending use of welded construction in the manufacture of steel plant and rolling mill equipment.

404 **Storage Batteries in Steel Mills**—The May issue of Exide News shows in illustrations the progress of iron from the ore to steel rails. The part storage batteries take in this process is briefly pointed out.

405 **Stress-Strain Recorder**—A folder prepared by the Baldwin-Southwark Corp., Philadelphia, Pa., describes their stress-strain recorder, tells how it works and gives typical graphs produced by this testing machine.

406 **Cadmium Plating**—The contributions of the Udylite Process Company to the cadmium plating industry are set forth in a pamphlet distributed by the company. The various services available to users of their process are enumerated.

407 **Wear of Metals**—The Link-Belt Co., 910 S. Michigan Ave., Chicago, Ill., is distributing copies of paper entitled "Relative Wear of Metals Due to Abrasion." It contains interesting data listing the Brinell Hardness and wear value of different materials as compared with a key steel.

408 **Grinding Tools**—Handbook and Catalog No. M 32 of the Carboloy Company, Inc., 2481 E. Grand Boulevard, Detroit, Mich., contains, in addition to the customary listing of their own tools, a section devoted to the manufacture, design, operation and maintenance of Carboloy tools and a section containing the listing of other tool manufacturers licensed to supply their tools equipped with Carboloy cemented carbide.

409 **Rustless Iron**—The Superior Steel Corporation, Pittsburgh, Pa., has compiled a pamphlet which gives the analysis and physical properties of their "Defirust," "Defistain" and "Defiheat" rustless iron. It includes a table showing the resistance of these irons to various media.

410 **Electric Furnaces**—Catalog No. 22 of the Ajax Metal Company, Philadelphia, illustrates their electric melting furnaces and gives specifications for them. One section of the catalog is devoted to a discussion of the principles of these furnaces and the advantages to be obtained in their use. This company is also distributing a reprint of an article entitled "The Development of the Electric Zinc Melting Process."

411 **Wrought Iron**—A most attractive booklet, "An Important Contribution to Metallurgy," prepared by the A. M. Byers Co., Pittsburgh, Pa., gives a pictorial review of the development of the large scale production of wrought iron and gives a detailed description of their new process. Another booklet issued by the same company is entitled "The Vital Element" and refers to the iron silicate, which, distributed throughout wrought iron, makes it so corrosion-resistant that wrought iron centuries old is still in excellent condition.

Co-operative Research at Battelle Memorial Institute. *Metal Progress*, Vol. 20, Nov. 1931, pages 83-86.
The facilities of the Institute for conducting metallurgical research are described. WLC (0)

Co-operative Metallurgical Research—How? H. W. Gillett. *Metals & Alloys*, Vol. 2, Dec. 1931, pages 360-364.
The author describes the methods and scope of coöperative research being conducted by government bureaus, educational institutions and private enterprises in the field of metallurgy. WLC (0)

The Law of Patents for Chemists. Joseph Rossman. Inventors Publishing Co., Washington, 1932. Cloth, 6 x 8½ inches, 304 pages. Price $3.50.
The author is a Patent Office Examiner as well as Editor of the Journal of the Patent Office Society, and dates his book from the Patent Office. He frankly gives the purely defensive use of patents against pirates as an important reason for taking out patents. "Patent protection is absolutely essential to cover the products of a commercial laboratory, not so much for the return that comes from a patented article as from the fact that others may patent work which has already been done and thus involve expensive litigation." He suggests that courses in chemistry and chemical engineering should include one in patent law.
The scope of the book is similar to that of several others recently published relating to chemistry and metallurgy. It explains the principles of patent law, what types of discoveries are patentable, the steps in obtaining the patent, and the drawing of claims, etc. It is understandably written and gives specific examples to illustrate the generalizations. The discussion of "subtractive patents" is clearer than in most other books on the subject.
While it is written primarily for chemists, some of the examples given are metallurgical and the principles apply to metallurgical patents. The author admits that the Patent Office is not infallible, and that it can overlook publications or not know all the common practice in an industry, and may thus allow patents to be issued that are not valid. This inside view of the situation from the Patent Office point of view does not increase one's admiration for the patent system as a whole, if one has any such admiration, but it does help in explaining the rules of the game.

Technology of Materials of Machine Construction. (Technologie der Maschinenbaustoffe.) Paul Schimpke. Sixth Edition, S. Hirzel Verlag, Leipzig, 1931. Paper 7 x 11 inches, 348 pages. Price 15 RM.
This textbook covers briefly but clearly the fundamentals of metallurgy from the engineering point of view. The production of the common metals and alloys, their properties, testing, casting, hot and cold working, joining by welding, etc. are described with sufficient illustrations of apparatus to show how most of the processes are carried out. German standard specifications are given for common metallic materials of construction.
Some of the sections are a bit sketchy, like that on electric steel, but in general, the volume would be a good text book for a technical school, and has value as a reference book.

The National Physical Laboratory; Metallurgy Department. *Engineering*, Vol. 132, Aug. 21, 1931, pages 224-225.
Brief description of the investigations in progress at the present time. These include researches on light alloys, materials for use at high temperatures, cracking of boiler plates, gases in molten Fe and mild steel, and a systematic study of the constitution, structure and physical properties of binary alloys of Fe. LFM (0)

Journal of the Institute of Metals, Vol. 44, 1930, No. 2, 880 pages.
This volume gives 17 original papers in some 430 pages, abstracts and book reviews in some 335, and over 110 pages of index. The abstracts will hereafter be issued in separate volume at the end of the year, while the usual semi-annual volumes of original papers will continue to be issued. The original articles and abstracts are of the usual order of excellence. H. W. Gillett (0)-B-

Directory and Buyer's Guide. *The Engineer*, London, 1932. Paper, 5¼ x 8¼ inches, 260 pages. Free.
Technical headings for the materials covered in this are given in English, French, German, Italian and Spanish. This takes up 34 pages. The bulk of the pamphlet is devoted to names and addresses of British vendors, listed under the articles they supply. The last 9 pages list the British Standard Specifications, among which are many of metallurgical interest. H. W. Gillett (0) -B-

Recent Progress in Metallurgical Research. *Fuels & Furnaces*, Vol. 9, Nov. 1931, pages 1267-1268.
A condensed account of reports to the 5th annual meeting of the Metallurgical Advisory Board to the Carnegie Institute of Technology and the U. S. Bureau of Mines. Subjects of research include determination of oxygen and of nonmetallic inclusions in steel, corrosion of Cr-Ni-Fe alloys and their magnetic properties, and the Fe-Mn-C system with application of dilatometric and X-ray methods of study.
CMB (0)

Development of Metallurgy. (Zur Entwicklung der Metallkunde.) G. Tammann (University of Göttingen). *Die Naturwissenschaften*, Vol. 20, Jan. 1, 1932, pages 1-6.
The paper presented at the Gesellschaft der Wissenschaften, Göttingen, Nov. 1931, goes back as far as pre-historic times. With regard to the modern conceptions on metals, attention is focussed on the following problems: working and shaping properties, crystalline structure, properties studied on single crystals, physico-chemical and chemical phenomena due to cold working, effect of subsequent heat treatment on changes due to cold working, results of grain growth investigations, significance of the grain size with reference to physicals, influence exerted by a second alloying element, information furnished by constitutional diagrams, hardening of steel and Al, corrosion problems of Al, Mg, Fe, Cr. EF (0)

PROPERTIES OF METALS (1)

The Strength and Cleavage of Bismuth and Antimony Crystals. (Ueber die Zerreissfestigkeit von Wismuth- und Antimonkristallen.) G. Wassermann. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 18, 1931, pages 35-38; *Zeitschrift für Kristallographie*, Vol. 75, Nov. 1930, pages 369-378.
Single crystals of Bi and Sb were prepared by slow solidification of the molten metals in a glass tube. Twinning could be produced early in either Bi or Sb single crystals by little deformation. Cleavage in Bi usually occurs on the basic plane (0001). The crystals were broken in torsion and in normal stresses and the cleavage faces calculated. When cleavage occurred on the rhombohedral face, twinning was observed. The critical normal stress on this plane was found to be 680 g./mm². Mügges hypotheses with respect to twinning were confirmed. The determination of the normal stress across a plane at fracture allows a quantitative comparison of the cleavability. 10 references. JLG+Ha+WHB (1)

Relations between Hall Effect and Resistance. F. W. Warburton & J. W. Todd. *Physical Review*, Vol. 37, June 1931, page 775.
Thin gold films show the same relation between the electric resistance and the Hall effect as has been observed for Te for temperatures between room temperature and 100° C. The phenomenon is explained by conduction of electrons.
Ha (1)

Bismuth, Its Production and Utilization. (Das Wismuth, seine Gewinnung und Verwendung.) *Die Metallbörse*, Vol. 21, Nov. 21, 1931, pages 2025-2026; Dec. 5, 1931, pages 2089-2090; Dec. 16, 1931, page 2138.
The occurrence and sources of Bi and its metallurgical production are given. Attention is called to the latest process of Thum (German Patent 296,662), Charuau & Babau (French Patent 449,507), Norsk Hydro Elektrisk Kvaelstofaktieselskab (Norwegian Patents and French Patent 541,291). The extensive use of Bi in a large variety of commercial applications based on several of its unusual properties is reviewed. EF (1)

Resistivities of the Metals at 18° and the Problem of Their Relative Abundance in the Universe—Distribution of Radiant Energy from the Sun. F. H. Loring. *Chemical News & Journal of Industrial Science*, Vol. 142, June 19, 1931, pages 385-388; June 26, 1931, pages 403-407; Vol. 143, July 3, 1931, pages 4-7.
The resistivities of the metals appear to be approximately 10^{-6} times the "probability no." evolved from the atomic numbers of the inert gases by the equation $(2 \times (1^2 + 2^2 + 3^2 + 4^2 + 4^2) + n^2)/n$, when n is 1, 2, 3, 4, 3, 2, 1, successively. The most abundant elements also tend to follow the probability numbers in distribution about as well as could be expected. The probability numbers yield a curve that is very similar to the curve for intensity of solar radiation throughout the spectrum. WHB (1)

Investigations on the Becquerel Effect IV (Untersuchungen über den Becquerel Effekt IV). I. Liefschitz & R. Reggiani (University of Groningen). *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 155, Aug. 1931, pages 431-450.
The occurrence and possibility of measuring Becquerel effects of second Order on electrodes other than noble metal electrodes is discussed. The authors urge a more accurate method of investigating Becquerel effects of first order. Measurements were performed on Nb, Ta, Fe, Zn, Cd-valve anodes as well as on electrodes of other materials. The valve effect is considerably reduced or entirely eliminated by the radiation W, Mo and passive Fe do not exhibit any effect, which is probably completely lacking in the case of passive metals. W-bronze displays none; graphite and carborundum display typical effects. For all kinds of Becquerel effects, a decrease in the apparent cell resistance due to the exposure to light was the significant criterion. Simultaneously the e.m.f. changes. Conclusions with respect to the nature of the effect are drawn therefrom. EF (1)

Iron Soft as Copper. A. E. Buchanan. *Scientific American*, Vol. 146, Jan. 1932, page 42.
Highly purified Fe, possessing many of the qualities of Cu, has been prepared in Germany by a new process by Dr. L. Schlecht. Carbon monoxide of a high degree of purity is passed over hot Fe previously purified by ordinary methods, forming liquid iron carbonyl. On heating this liquid, carbon and oxygen are driven off, leaving iron in an exceedingly fine powdered form with hardly a trace of impurities. The individual spherical particles are estimated to be 20-millionths of an in. in diameter. When this powder is heated to a temperature of 1200° C., it is converted into solid Fe that resembles Cu in its softness, resistance to corrosion and other properties. The process is claimed to be applicable to large scale production. WAT (1)

Observations on the Pressure of Fluidity of Annealed Metals. Hugh O'Neill & Hubert Greenwood (The University, Manchester). *Institute of Metals, Advance Copy* No. 595, Apr. 1932, 21 pages.
The pressure of fluidity is that pressure at which a loaded punch continuously penetrates a block of ductile metal. Tests on blocks of metal subjected to the fluidity test showed that the most highly strained portions of the block had a Meyer's ball index No. $n = 2.0$, and a resistance to indentation equal to the pressure of fluidity. This latter value can therefore be determined from a ball test on metal cold rolled to the greater possible degree. The pressure required to extrude a metal through a die is roughly equal to the pressure of fluidity or to 2 times the Brinell hardness number of the annealed material. The tensile test is analyzed, and it is concluded that the true stress plotted against the relative reduction in diameter is a straight line above the maximum load, as found by Stead. A correlation between tensile, compressive, indentation and punching tests is suggested. Tests on annealed wires drawn to 20% reduction in 1 pass indicated that the maximum stress required for drawing under such conditions was much lower than the pressure of fluidity. 23 references. JLG (1)

Thickness of Standard Copper Sheets—Rolled to Weight. J. K. Olsen. *Metal Stampings*, Vol. 4, May 1931, page 442.
This table gives the thickness in decimal parts of an in. of rolled Cu sheet weighing from 20 lbs./ft.² to 1 oz./ft.². One ft.³ of Cu weighs 555.56 lbs. JN (1)

Outlook for Zinc. A. P. Cobb (New Jersey Zinc Co.). *Mining Congress Journal*, Vol. 17, Nov. 1931, pages 594-596.

In all times a large part of the annual production of metallic Zn is used in galvanizing or "zinc-coating." There is more use for prime Western slab Zn, often called "common metal." American Zinc Institute is studying advantages of more heavily zinc-coated sheets. Special zinc-coating jobs require high grade Zn, such as Horse-head & Horse-head Special. Today, Zn is being used in large scale electrification of railroad lines, for signal cable wrapping, in radios, for eyelets, grommets, shoelace tips and other stable items. The use of rolled Zn for automobile running-board molding is increasing. The plating of rolled Zn and Zn die-castings is an important matter for an extension of markets; almost any type of finish may be applied and any kind of electroplated coating. Refrigerator hardware is attracting the white metal. Zn for die castings is gradually passing away from the biggest obstacle to its use in the past—prejudices due to unfortunate experiences. Horse-head Special 99.99+% is used. New Zn alloys are being perfected for service in fields where present alloys have not all the qualities required. In the paint industry, Lithopone (28-30% ZnS) is the most commonly used white paint pigment. The perfectly prepared Lithopone paints, ZnS and ZnO, are naturally and permanently white and slow chalking of Zn pigment paints means economy together with no change in the color during the life of the paint. Lithopone paints have more covering power than any other type of paint. There is also the high ZnS pigment field, cryptones. Consumption is smaller than that of Lithopone, but cryptones contain nearly twice as much ZnS. ZnO is a fixture in paint technology due to extra-durability to all paint films, washability to wall paints and slower chalking to outside house paints. Zn dust pigment has come to the fore, especially since ZnO has been mixed with it to reduce the high specific gravity. It is more efficient as a corrosion-resistant agent than any other standard metal priming paint. A special characteristic of Zn dust (ZnO) paint when used on black iron or steel is the tenacity with which the priming coat adheres to the metal. DTR (1)

Relation of Rolled-Texture, Deep Drawing Properties and Hardness of Ag, Cu, Al, and an Ag-Cu alloy. (Experimentelle Studien über den Zusammenhang zwischen Walztexture, Tiefziehfähigkeit und Härte bei den Metallen Ag, Cu, Al und einer Ag-Cu Legierung). H. Holzmann. *Siebert Festschrift*, 1931, pages 121-148.

The Ag-Cu alloy contained 83.5% Ag, 16.5% Cu. Above 40% reduction in rolling, the Brinell hardness of material rolled in one direction only is higher than on material cross rolled, for Cu, Al and the Ag-Cu alloy, while for Ag it is higher at all reductions. The Erichsen value of the Ag-Cu alloy falls off very rapidly at reductions of 60% and over, while, if the sheet is turned 90° at each 1/10 mm. reduction in thickness, the Erichsen value is as good at 98% reduction as at 50%. With no cross rolling, the Erichsen value for Ag reaches a minimum at 85% reduction, for Cu at 90% and for Al at 65%, and then improves slightly. Material annealed after rolling without and with cross rolling was also subjected to the Erichsen test. It made no difference on Ag whether or not the reduction had been by cross rolling, but above 80% reduction on Cu, 95% on Al and 80% on the Ag-Cu alloy, the depth of cup was less on material rolled in one direction only, while cross-rolled material showed no injury. The angle of nip in rolling was varied from 90° to 45° and 22½° without altering the results. HWG (1)

Metal Contacts with Films. (Vorläufige Mitteilung über Metallkontakte mit sehr dünner Fremdschicht.) R. Holm. *Zeitschrift für technische Physik*, Vol. 4, Dec. 1931, pages 663-665.

Films are rapidly formed on base metal surfaces in air. Although they destroy metallic adhesion, the films actually do not materially affect the electrical resistance of the contacts at ordinary temperatures, the conductivity being of a peculiar type. With falling temperature the conductivity does not change essentially until supraconductivity occurs as is the case with Sn. EF (1)

Mercury for Dental Amalgams. Aaron Isaacs. *Journal American Dental Association*, Vol. 19, Jan. 1932, pages 54-57.

The purpose of the investigation was to compare the quality of various grades and brands of Hg available to the dental profession and to develop a specification for Hg satisfactory for use in dental amalgams. To Hg which had been carefully purified 0.001% of Cu, Zn, Sn, Pb, Bi, Cd, As, Sb, Ag and Au were added as impurities. The As was only partly, if at all, dissolved. The presence of any of these metals except Ag and Au was readily detected by the film or "skin" formed on the surface of the mercury. The Ag and Au were detected as non-volatile residues. Of 5 commercial samples of U. S. P. Hg all were free from non-volatile residues. Of 8 samples of Hg graded as "Dental C. P." only 4 showed non-volatile residues, which were Ag in every case and not harmful for use in dental amalgams. Glass containers were found to be better than wood or stoneware. A mirror surface on the mercury indicates the absence of the base metals, and specification No. 6 of the American Dental Association permits not more than .02% of non-volatile residue. Clean, clear glass containers are required. OEH (1)

Festival Volume for the 50th Anniversary of the Siebert Platinum Works. (Festschrift zum fünfzigjährigen bestehen der Platinschmelze G. Siebert, G. m.b.H. Hanau.) Edited by H. Houben. G. M. Alberti's Hofbuchhandlung, Hanau, 1931. Cloth, 6½ x 9½ inches, 338 pages. Price 10 RM.

Following a brief history of the Siebert organization and list of its products, there are given 20 articles on precious metals by 28 authors and collaborators. Five of the articles are on purely chemical subjects, the balance are metallurgical and of importance to those interested in the rare metals. Especially important are the articles on thermocouples, effect of other elements on the Au-Pt system, effect of oxides on Pt at high temperatures, and on X-ray studies of Ag Pd, Au Pd and Au Pt.

The metallurgical articles are separately abstracted.

The Contribution of Protons to the Electric Conductivity of Metals. (Ueber die Beteiligung von Protonen an der Elektrizitätsleitung in Metallen.) D. P. Smith. *Zeitschrift für Physik*, Vol. 69, May 1st, 1931, pages 253-258.

On the basis of observations on Pd charged with hydrogen the part of the protons in the conductivity is discussed. It seems that the conductivity does not only depend on the existing protons but also on other slow electrolytic transformations. Ha (1)

Electrical and Mechanical Effects on Metallic Wires by Thermal, Magnetic or Acoustic Influences on the Structure. (Elektrische und mechanische Effekte an Metalldrähten bei thermischer, magnetischer oder akustischer Beeinflussung der Struktur.) A. V. Hippel & O. Stierstadt. *Zeitschrift für Physik*, Vol. 69, Apr. 23, 1931, pages 52-55.

If a lattice element passes from one well defined energetic state into another a sudden dislocation of the electric charge must take place and consequently a dislocation current should be observed in a suitable device. This was proved to be true by leading the amplified current to a loud-speaker. Heating of an iron wire, magnetizing, cooling below the Curie point in a magnetic field, and pulling extended wires produced sounds in the loud-speaker. Ha (1)

Note on the Coefficient of Thermal Expansion of Gallium and the Products $a \times T_s$ of the Elements. (Notiz über den Ausdehnungskoefficienten des Galliums und das Produkt $a \times T_s$ bei Elementen.) Wilhelm Klemm. *Zeitschrift für anorganische und allegemeine Chemie*, Vol. 198, May 28, 1931, pages 178-183.

(1) The cubic coefficient of thermal expansion between 18° and — 78.3° C. of Ga (containing In 0.16, Zn 0.10, Pb 0.10%) is 5.3 (± 0.5) × 10^{-5} and its density at 25° C., 5.913. (2) Curves are given and discussed showing the values of $1/T_s$, $a \times 10^{-5}$, and $a \times T_s$ of the elements against the atomic number, a and T_s being the coefficient of thermal expansion at room temperature and the melting point in degrees absolute respectively. WHB (1)

Study of the Bending Elasticity of Iron, Copper, Gold, Silver, Platinum, Fused Silica, and Nickel. (Etude sur l'elasticite de flexion Fer- Cuivre- Or- Argent- Platine Verre de silice- Nickel.) A. Jacquerod & H. Mügeli. *Helvetica Physica Acta*, Vol. 4, Feb. 16, 1931, pages 3-30.

Young's moduli of the metals were determined from the time of swing of a torsion pendulum to which spiral springs of the metals were attached. The results obtained were as follows:

Metal	State	E at 0° C. Kg./mm.²	Temperature Coefficient 0°-100° C. × 10^{-4}
Copper	drawn	12,870	3.986
Gold	annealed	8,060	3.988
Silver	"	9,300	5.715
Platinum	"	19,900	0.75
	drawn	22,100	3.108
Nickel	annealed	20,400	10.56

The precious metals were annealed for 100-120 hrs. at 142°-145° C. and the Ni for 10 hrs. at 585° C. The values for Ag altered appreciably over a long period. WHB (1)

Revision of the Atomic Weight of Calcium. Atomic Weight of Calcium from Sylvite. (Revision des Atomgewichtes des Calciums Atomgewicht des Calciums aus Sylvin.) O. Hönigschmid & Käte Kempter. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 195, Jan. 7, 1931, pages 1-14.

The atomic weight of Ca was found to be 40.085 ± 0.00060, i. e. a little higher than the mean value of all determinations by Richards and by Hönigschmid since 1903 (40.078). The atomic weight of Ca prepared from sylvite was found to be 40.091 after taking into consideration the possibility of the presence of traces of Sr. WHB (1)

Some Photoelectric and Thermionic Properties of Rhodium. E. H. Dixon. *Physical Review*, Vol. 37, Jan. 1931, pages 60-69.

The photoelectric current of a thin strip of Rh increases 130% from 25° to 950° C.; at 240° C. a sudden increase took place. Another anomaly was found at 1100° C. where the photoelectric current became irregular and the resistance temperature coefficient changed. Ha (1)

The Half-Value Period of Uranium. O. Gratias & C. H. Collie. *Proceedings Royal Society*, Vol. 135A, Mar. 1932, pages 299-306.

The half-value period of uranium has been redetermined; the ionisation current was measured by an electrometer, and a null method in which the current from the uranium was balanced by that from a variable polonium source. These gave as a mean of 5 concordant determinations $\lambda = 8.02 \times 10^{-6}$ sec.$^{-1}$ corresponding to a half-value period of 24.0 ± 0.58 hours. WAT (1)

The Boiling of Some Metals and Alloys at Atmospheric Pressure. (Ueber das Sieden einiger Metalle und Legierungen bei Atmosphärendruck.) W. Leitgebel. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 202, Dec. 24, 1931, pages 305-324.

The tests were made in a high-frequency furnace where the metal was in motion during the measurements; the newly made determinations of boiling points were:

Cadmium	767° ± 2° C.	Bismuth	1560° ± 5° C.
Zinc	907° ± 2° C.	Antimony	1635° ± 8° C.
Magnesium	1097° ± 3° C.	Lead	1740° ± 10° C.
Thallium	1457° ± 10° C.		

Boiling curves of the following systems were investigated: Al-Mg, Al-Zn, Bi-Pb, Bi-Sb, Cd-Pb, Cd-Mg, Cd-Zn, Cu-Zn, Mg-Pb, Mg-Sb, Mg-Zn, Pb-Sb, Pb-Te, Pb-Zn, Sb-Zn. A maximum in the boiling curve was found for Bi-Sb and Pb-Sb. The increase in the boiling point of binary systems was the greater the smaller the atomic weight of the added metal. The ternary system Cd-Pb-Zn was also investigated, the boiling point of Cd increases fairly uniformly up to the boiling point of the system Pb-Zn. 90 references. Ha (1)

The Development of Research on Rhenium since 1925. (Die Entwicklung der Rheniumforschung seit 1925.) W. Noddack. *Die Metallbörse*, Vol. 21, July 22, 1931, page 1374.

The rapid historical development of rhenium since its discovery is reviewed at the General Meeting of the Verein Deutscher Chemiker, Vienna, 1931. EF (1)

Platinum. Donald McDonald. *Canadian Chemistry & Metallurgy*, Vol. 16, Feb. 1932, pages 28-30.

An abstract dealing with the purification and metallurgy, physical and chemical properties, uses and economics of Pt. WHB (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Modern Die Casting of Aluminum. G. M. Rollason (U. S. Aluminum Co.) & Sam Tour (Lucius Pitkin, Inc.). *Metal Progress,* Vol. 21, Jan. 1932, pages 32-37.

Gives summary of advantages, limitation and applications of Al die castings. Discusses briefly the effects of small amounts of Cu, Fe, Zn, Si, Sn, Mn and Cr on the alloy. A table shows the physical properties and compositions of typical alloys. Machining, polishing, plating and dipping of castings are discussed. WLC (2)

Nickel in Aluminum Brass. W. B. Price. *Metals & Alloys,* Vol. 2, Dec. 1931, page 366.

Abstract by H. W. Gillett showing compositions and properties of these alloys. WLC (2)

Zinc Die Castings. W. M. Peirce (N. J. Zinc Co.) & Marc Stern (AC Spark Plug Co.). *Metal Progress,* Vol. 20, Dec. 1931, pages 53-58.

Application of Al:Cu:Mg, 4:3:0.1% Zn base die castings to a wide range of parts are described: typewriter frames, radio chassis, electric fan housings and clock cases. Composition as to impurities is held to less than 0.02% with Al 3.5/4.5%, Cu 2.5/3.5% and Mg 0.02/0.12%. Effects of aging on the properties are tabulated. Material has an average tensile strength of 44,000 lbs./in.^{2} with average elongation of 2.0%. Other physical properties, density, melting point, hardness, thermal expansion, thermal and electrical conductivity are given. Machining characteristics are discussed with recommended clearance angles. The electroplating of Zn die casting is briefly discussed. WLC (2)

Plasticity of Copper-Zinc Alloys. Alan Morris. *Metal Stampings,* Vol. 4, Apr. 1931, page 320.

Abstract of a paper presented at the New York meeting of The American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys,* Vol. 2, June 1931, page 112. JN (2)

Antifriction Alloys with Magnesium Base. A. M. Bochvar & F. A. Luneff. *Tsvetnui Metallui,* Sept. 1931, pages 1135-1139.

Mg-Si, Mg-Ca, and Mg-Si-Ca alloys were studied. It was found that of the 3 systems only Mg-Si alloys can be used as antifriction light weight alloys. The alloys with from 1.68 to 3.21% Si possess a suitable structure, melting point of 650° to 700° C. depending on the Si content, and Brinell hardness from 30 to 40 (Shore 12 to 16). BND (2)

Alloys of Platinum with Iridium. (Legierungen des Platins mit Iridium.) W. A. Nemilow. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 204, Feb. 9, 1932, pages 41-48.

The Pt was investigated with 0 to 100% additions of Ir. The Brinell hardness shows at 50% a maximum of 256.4 kg./mm^2. The drawing of wires with more than 20% Ir is very difficult, the tearing strength of the 20% alloy was 61.3 kg./mm. The microstructure of all alloys shows solid solutions; annealing changes the structure only slightly. The specific electric resistance increases with the increase of Ir which proves the presence of a solid solution. The temperature coefficient shows a minimum at about 45% Ir. All test results are reproduced in detail; 12 references. Ha (2)

Aluminum-Brasses. (Ueber Aluminium-Messinge.) B. Blumenthal. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Jan. 9, 1932, page 43.

The Al-brasses have a greater strength and elongation than ordinary brass if the thin oxide film formed by molten Al does not get into the block. The oxide film prevents the evaporation of Zn; an addition of 0.1% being sufficient. Albrass is very suitable for condenser tubes, particularly the composition of 76% Cu, 22% Zn, 2% Al; this alloy is very resistant to corrosion. Ha (2)

Note on Bearing Metals with a Pb-Sn Base (Beiträge zur Kenntnis der Lagermetalle auf Blei-Zinn-Basis). A. Demmer. Doctor's thesis, University of Bonn, 1931, 45 pages.

The data are tabulated from which were drawn the compression curves and the elevated temperature hardness curves for Pb-Sn-Sb alloys with and without Ni, Mg, P, or Cu, in the report by E. Hertel and A. Demmer, *Metallwirtschrift,* Vol. 10, February 13, 1931, pages 125-126. See *Metals & Alloys,* Vol. 2, July 1931, page 126. HWG (2)

Nickel-Copper Alloys of High Elastic Limit. Jones, Pfeil & Griffiths. *Engineer,* Vol. 152, Sept. 25, 1931, page 331.

Abstract of paper read before the Institute of Metals, Zurich, Switzerland, Sept. 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 297. LFM (2)

Everdur Metal—A High Strength, Corrosion Resistant Engineering Material. C. B. Jacobs, Jr. *Metals & Alloys,* Vol. 3, Jan. 1932, page 26.

The physical properties comparable to steel, of a Cu alloy of 4¼% Si and 1.2% Mn are described. The alloy is very easily worked and exhibits excellent corrosion resistance for a variety of applications. WLC (2)

Aluminum Alloys Used in the Foundry. (Les alliages d'aluminium utilisés en fonderie.) Jacques Douchement. *Revue de Métallurgie,* Vol. 28, Oct. 1931, pages 557-564.

A review of the properties of Al alloys as applied to castings for the aviation industry. Among them is described a French alloy, Eutectal (1.5 Cu, 0.8 Mn, 0.35 Ti, 1.58 Mg_2Si), which, after soaking for 6 hrs. at 525° C., quenching and drawing for 9 hrs. at 150° C., has an elastic limit of 23.5 kg./mm.^{2}, tensile strength 27.7 kg./mm.^{2} and Brinell hardness 98. JDG (2)

Studies in Lead-Alloys. (Studien über Bleilegierungen.) B. Garre & A. Mueller. *Zeitschrift anorganische und allgemeine Chemie,* Vol. 198, June 10, 1931, pages 297-309.

A considerable increase of hardness was observed in Pb-Cd-Sb alloys after quenching and aging. A general temperature-concentration diagram between Pb and CdSb was determined and the hardness measured under various conditions; cold-working is not necessary for hardening. At definite ratios of additions of Cd and Sb quenching is not necessary, hardening takes place after normal cooling. Additions of Sn and Zn do not promote hardening. The property of commercial Pb to become brittle below the melting point is due to the melting of eutectics. Pb of coarse grain is brittle under certain conditions; breaking without noticeable deformation. A number of aging and equilibrium diagrams are reproduced. Ha (2)

Magnesium Alloys. Correspondence from F. Giolitti, Turin, Italy. *Metal Progress,* Vol. 21, Jan. 1932, pages 68-69.

Notes on the recent industrial exhibit at Milan and the increased interest in light magnesium alloys evident among Italian manufacturers. WLC (2)

Preparation and Some Physical Properties of Sr-Cd Alloys. H. C. Hodge, *et al.* (College of the Pacific, Stockton, Calif.). *Metals & Alloys,* Vol. 2, Dec. 1931, pages 355-357.

8 references. Sr-Cd alloys were prepared by electrolysis of eutectic mixture of $SrCl_2$ and NaCl over a bath of molten Cd in a suitably wired crucible. The Cd served as cathode and a carbon rod as anode. Thermal analyses of alloys up to 26% Sr are reported. Micrographs show the structures observed in cast and annealed conditions. Curves show the effect of Sr in increasing the hardness and specific gravity of the alloys. WLC (2)

Melting and Casting of Aluminium Bronzes. Edmund R. Thews. *Metallurgist,* Oct. 1931, pages 159-160.

The Cu-Al alloys employed for artistic and chemical purposes as well as in marine engineering usually contain, besides Cu, about 8 to 12% Al and smaller percentages of Fe or Ni (1 to 4%). Fe, Mn, Ni, and, to some extent, Si may be considered desirable constituents if present in suitable proportions, while As, P, and Sb are distinctly harmful. Virgin metals only should be used. 0.3%-1.00% Mn tend to improve the resistance to atmospheric corrosion and sea water as well as the tensile strength, without lowering the ductility of Al bronze castings. Larger percentages result in very appreciable deterioration of the casting properties. The addition of Ni improves the density and the corrosion resistance of the castings to sea water. Small percentages of Zn serve to counteract the tendency of straight Al bronzes to form coarsely crystalline structures, but exert a distinctly deteriorating influence on their mechanical properties and, since the only advantage of Zn is also shared by Fe—in percentages above 4—, the alloys of this group should preferably be maintained from Zn. The addition of from 1.0 to 1.5% Pb improves the cutting qualities of the castings without appreciably deteriorating their chemical and mechanical properties and their structure. Straight Al bronzes are produced by first melting down and deoxidizing the Cu, then adding the required quantities of Al in the form of a 50/50 hardener. It is absolutely necessary before adding the Al thoroughly to deoxidize the Cu by means of phosphor copper. The methods used for producing the hardener are: (1) adding solid Al to fused Cu; (2) adding fused Al to liquid Cu; (3) adding liquid Cu to fused Al, (4) adding solid Cu to fused Al. Method (4) is generally used in the United States and (3) in Continental countries. These are described in detail. Detailed directions given for pouring Al bronzes. (2)

An Investigation of Duralumin Wire. I. G. Shoulgin. *Transactions of the Central Aero-Hydrodynamical Institute,* No. 83, May 1931, 44 pages, 40 illustrations. (In Russian).

Physical properties of duralumin wire of different diameters and subjected to different heat treatments were investigated. General observations regarding the temperature effect are given. (2)

Cast Gold Alloys: Their Physical Properties and Dental Application. J. S. Shell. *Journal American Dental Association,* Vol. 18, May 1931, pages 904-916.

Hardness, tensile strength, elongation, elasticity, endurance strength, and the relation of these properties of cast Au alloys to their application in dental work is discussed. A refining is possible by partial transformation of the solid solutions into the intermetallic compound AuCu. Alloys of 70% Au, 5% Pt, 15% Cu, and the remainder of Ag, Pd, Zn increase their strength from 46 to 70 kg./mm.^{2} by heating at from 250-425° C. Ha (2)

Lead-base and Tin-base Alloys for Die Castings. F. J. Tobias. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 1, 1931, pages 280-283.

Aluminium, Its Alloys and Some Applications. *Metallurgia,* Vol. 5, Apr. 1932, pages 203-206.

A review. Mentions ores, production of Al, use and properties of Al and its alloys. JLG (2)

Copper-beryllium "Bronzes." J. Kent Smith (Beryllium Development Corp.) *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 465, Feb. 1932, 14 pages.

Bibliography of 11 references. Describes a series of experiments in which Be-Cu alloys containing as much as 2.75% Be were tested in the wrought condition. Both hardness and tensile tests showed that alloys containing over 1.5% Be could be hardened by quenching and aging .The strength and hardness of the age-hardened alloys could be materially increased by cold work. Tensile strengths as high as 220,000 lb./in.^{2} resulted from age hardening and then rolling a 1.91% Be alloy. The alloys were made from a 12-15% Be master alloy, which is now commercially available. JLG (2)

Copper-Titanium Alloys. *Metallurgist,* Oct. 1931, pages 157-158.

An extended abstract of *Technical Publication* No. 432, *American Institute of Mining and Metallurgical Engineers* by F. R. Hensel and E. I. Larsen. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 298. VVK (2)

Technology and Utilization of Electron Metal. (Technologie und Anwendung des Elektronmetalls.) W. Schmidt. *Die Metallbörse,* Vol. 21, June 27, 1931, page 1206.

Composition, physical properties, corrosion resistance, refining processes, casting, hot working and shaping, utilization in aviation and automobile industry are considered in a paper before the Deutsche Bunsengesellschaft für angewandte physikalische Chemie, 1931. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 2. EF (2)

A New Aluminium Alloy. *Electrical Times,* Vol. 81, Jan. 7, 1932, page 23; *Metal Industry,* London, Vol. 40, Jan. 1, 1932, page 14.

The new alloy MG7, produced by James Booth & Co., Ltd., is composed of Al, Mg and Mn. Its specific gravity is 2.36, the mechanical properties are similar to "Duralumin." It is not capable of heat treatment, but application of cold work hardens quickly. The resistance to corrosion particularly that of sea water is extremely high. Effect of same corroding medium within 100 days: MG7 25.1; Duralumin 19.5; Soft Al. 5.06 in max. stress-tons/in. WR (2)

Improving Service of Steel Castings to Industry. *Steel,* Vol. 88, Feb. 26, 1931, pages 41, 43, 53.

As a result of improved manufacturing methods, better metallurgical control, and closer attention to markets and to service requirements, the steel foundry is now in a strong competitive position. Better control of melting operations, more exacting supervision, and closer inspection have resulted in the universal production of stronger castings. A representative air-quenched and drawn cast steel has a tensile strength of 70,000 to 80,000 lbs./in.^{2}, a yield point of 40,000 to 50,000 lbs., an elongation of 22 to 30%, and a reduction in area of 30 to 50%. The physical properties of cast steel are discussed at some length. The new foundry and new heat treating unit of the Lebanon Steel Foundry, Lebanon, Pa., are described. JN (3)

The Practical Application of New Formulae for Determining the Quality of Cast Iron. *Foundry Trade Journal,* Vol. 45, Oct. 29, 1931, pages 265-266.

The Changes of Electric Conductivity of Ferromagnetic Materials in Magnetic Fields. (Die Aenderungen der Elektrischen Leitfähigkeit Ferromagnetischer Stoffe in Magnetfeldern.) O. Stierstadt. *Zeitschrift für technische Physik,* Vol. 13, No. 2, 1932, pages 65-71.

The apparatus and methods used in the tests and the theory of the measuring methods are explained and a few hysteresis curves in magnetic fields for several materials are reproduced. The author shows that the exterior magnetic field does not define the physical condition of a ferromagnetic material, but the interior field, the magnetic induction or the magnetization. For a theoretical explanation the magnetization curve B=f(h) must be plotted together with the change of resistance and the changes be represented as function of the inner field B. The virginal magnetization curve can then be expressed very closely by $dw/w=c\times B^x$; the exponent x for Fe and Ni lies between 3 and 4, the constant c is of the order 10^{-15} to 10^{-20}. Ha (3)

Fabricating Stainless Steel. C. C. Snyder (Republic Steel Co.). *Machinery,* Vol. 38, Nov. 1931, page 173.

Abstract of a paper before the Indiana section of the Society of Automotive Engineers. Steel known as 18-8 or Krupp Nirosta KA-2 has unusual ductility after heat-treating at 2000°-2100° F. They are readily welded by spot, resistance, arc and acetylene methods. For drawing sheets special lubricants are used; such as a mixture of lithopone and linseed oil to which chalk and sulphur are sometimes added. For pickling solution use 8% H_2SO_4 and 2% HCl to be followed by a 20% HNO_3 bath. (Acid percentage by volume.) Pickling temperature 130°-160° F. For polishing, use abrasive having a grit of 150-180 to be followed by 200 emery, 240 flour and alumina buffing compound. RHP (3)

Eutectic Cast Iron. B. Osann. *Bulletin British Cast Iron Research Association,* Vol. 3, Oct. 1931, pages 38-41.

It is emphasized throughout the paper that the pearlitic condition is the ideal condition to be sought if good castings with suitable mechanical properties are to be obtained. In addition, it is pointed out that for some services where corrosion is likely to be encountered, the uniformity of the pearlitic structure tends to eliminate the setting up of electric currents between the various constituents of the iron. The author's meaning of the word "eutectic" is derived from the Greek roots meaning "well made," and is not the usual interpretation most metallurgists put on the word. WAT (3)

Cast Chromium Steels in Wider Use. Electric Furnace Melting Processes Used for Corrosion-Resisting Alloys. H. D. Phillips. *Steel,* Vol. 88, Jan. 8, 1931, pages 39-43.

Ferrous alloys of Cr, or of Cr and Ni, fall into 3 groups: ferrites, martensites and austenites; the last being the desired solid solutions. High Cr content in steel reduces the per cent of C in the eutectic; raises the critical temperature; diminishes the rate of carbon diffusion; imparts the property of air hardening when the C content exceeds 0.1%. The addition of Ni to steel lowers the critical temperature, increases the hardness and strength without correspondingly decreasing the ductility and tends to produce a finer grain structure. The 3 types of Ni steels are: pearlites, martensites, and austenites. The presence of both Ni and Cr in steel is mutually beneficial. The addition of Ni to a high Cr steel produces an austenitic structure, as does also the addition of Cr to a high Ni steel. Austenitic alloys are fine grained, strong, tough, ductile, non-magnetic and highly resistant to both corrosion and machinability. The best method of producing high Cr and Cr-Ni alloy steels is in the electric furnace. The author describes both the acid and basic electric furnace processes with notes on pouring temperatures, heat treating and hardening practice. Tables are given to show the chemical compositions and physical properties of 6 typical alloy steels. JN (3)

Grate Wear caused by Heat Given off from Upper Silesian Fuels. (Rostverschleis durch Wärmeeinfluss bei oberschlesischen Brennstoffen.) *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Jan. 1932, pages 7-9.

The investigations covered tests made to determine the composition of the rust, the cause of wear, the chemical and physical behavior of the fuel residue as well as the homogeneity of the material. The results of operating different plants under different conditions are compared. MAB (4)

Scientists Learn Effects of Cleaning on Metals. *Scientific American,* Vol. 146, Apr. 1932, pages 236-237.

The effect of disinfectants and cleaning on metals has been studied in Germany. Sheet samples of 40 different metals were immersed from 24-48 hrs. at certain temperatures in 24 disinfectants and cleaning solutions. The samples were carefully cleaned, loss of weight was determined and examined microscopically. Fe and steel were attacked by most of the solutions, and Cu was not much better. Zn was found to resist their action poorly, while Al and Al alloys were attacked by all acid and alkaline solutions. Tinned steel and tinned Cu were fairly satisfactory. Ni, Ni alloys, stainless steel and Cr plated steels were best. WAT (4)

The Constitution of Scale. L. B. Pfeil. *Engineering,* Vol. 131, May 15, 1931, pages 651-652.

Corrosion of Cast Aluminum Alloys. W. O. Kroenig. *Transactions, Central Aero-Hydrodynamic Institute,* No. 91, 1931, 32 pages. In Russian.

Specimens for the investigation were prepared by casting into a chill 17 alloys both of the standard composition as No. 12, silumin and duralumin and those made by the addition to commercial aluminum of Cu, Mg, Mn, Zn, Sb and Sn, either in combination or separately. The castings in the shape of plates 250x170x15 mm. were cut into 2 corrosion specimens, one of which was machined all over, the other with the casting skin left intact, and corroded in a machine previously described (W. Kroenig, *Korrosion und Metallschutz,* 1930, page 25) using sea water to which some H_2O_2 was added. The attack lasted 15 days. Weight losses gave widely discrepant results. A comparison of the physical properties before and after corrosion was used as a criterion of corrosion resistance. All alloys containing Cu corrode badly and the corrosion is further increased by addition to them both of Zn and of Mn, while an addition of 0.2% Sb somewhat improves it at the expense of greatly reduced physical properties. 1% Sn added to No. 12 metal has no effect. Of the Al-Mg alloys, the most resistant is a 5% Mg alloy. The addition to 2.5% Mg alloy of 1.5% Mn considerably increases the resistance to corrosion and increases the strength of this somewhat weak alloy. The best results were obtained with the composition: 2.29 Mg; 1.85 Mn; 0.17 Sb. Theoretical considerations are advanced to explain the mechanism of corrosion. 18 photomicrographs are given. See also *Metals & Alloys,* Vol. 2, Nov. 1931, page 247. (4)

Chemical Corrosion of Lead in the Presence of Phenol (La corrosione chimica del piombo in presenza di fenolo). E. Da Fano. *Giornale di Chimica Industriale ed applicata,* Vol. 14, Jan. 1932, pages 18-21.

Buried lead corrodes rapidly; it is exceptional when it remains unaltered for 5 or 10 years. Protective coatings of coal tar containing anthracene oil, used on Italian telephone cables, were suspected of playing a part in accelerating corrosion. Laboratory tests indicated that such coatings, instead of delaying corrosion, may accelerate it, due to the presence of phenol which acts in a cyclic process as a sort of catalyzer, the lead phenolate formed being decomposed by CO_2 with regeneration of phenol. Besides having the proper consistency to keep out moisture, the coating should be as free as possible from phenol, even though phenol would not cause corrosion were moisture and CO_2 completely excluded. However, such complete exclusion is not commercially attained. HWG (4)

Non-Metallic Films which remain as residue in the Dissolution of Tin. (Nicht-metallische Häutchen, die bei der Auflösung von Zinn als Rückstand verbleiben.) A. Kutzelnigg. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 202, Dec. 24, 1931, pages 418-419.

The residue was determined as the substance between the metal crystallites, similarly to former tests with Cd. The amount of residue which shows a mesh-like structure was determined to be 0.0176% of the dissolved material. 7 references. Ha (4)

Autoxidation of Zinc. (Autoxydation des Zinks.) Al. St. Cocosinschi. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 197, Apr. 30, 1931, pages 270-272.

Chemically pure and somewhat impure Zn were left for 7 months in distilled water with more or less access of air. Zinc carbonate is formed whose content of CO_2 depends on the access of air. Pure Zn is not attacked if air is excluded, impure Zn is oxidized even in the absence of air. Water is not decomposed by chemically pure Zn. The autoxidation is greatly dependent on the disintegration of water. Ha (4)

Soil Corrosion. Wm. Thompson Smith (Ford, Bacon & Davis, Inc.). *Gas Age-Record*, Vol. 66, Dec. 20, 1930, pages 987-990, 997.

A paper prepared for the Bureau of Standards Second Soil Corrosion Conference, Dec., 1930. The 340-mile Amarillo-Denver natural gas pipe line was laid in 1927-1928 and protected in accordance with a corrosion survey. 2 years later it was inspected with, in part, the following conclusions. The substantial accuracy of the results of a soil corrosion survey as used by Ford, Bacon & Davis, Inc. is confirmed for alkali soils. The specifications of the degree of protection to be used on a pipe line is more exactly in accord with the actual requirements when based on a soil corrosion survey than when based upon surface inspection alone. The variation from the degree of protection necessary, as indicated by actual inspection after services, tends toward provision of excess coating in the case of a soil corrosion survey and toward inadequate protection in the case of surface inspection alone. Agreement by independent observers as to the degree of corrosiveness of the soil at any location is not absolute even when based on inspection data of pipe after service. It is unsafe to base a decision to eliminate protection at any point on the old method of simple inspection of the surface of the ground alone. It is relatively safe to base specifications of pipe protection on the results of a thorough soil corrosion survey. Substantial agreement in the comparative rating of soil samples as to relative corrosiveness, although a matter of judgment, is possible by independent workers. In the instance studied, soil corrosion survey specifications would have entailed an expenditure for pipe protection of 6.4% more than actually required. The actual construction program (although only in part substituting simple surface observations for a soil corrosion survey) expended only 75.1% of the amount actually required for adequate protection. This study has shown no one factor or small group of factors affecting corrosion which may safely be taken as an index of the comparative corrosiveness of soils at various locations. VVK (4)

Relation of Pipe Line Currents and Soil Resistivity to Corrosion. C. R. Weidner & L. E. Davis (Prairie Pipe Line Co.). *Proceedings American Petroleum Institute*, Dec. 1931, Section IV, pages 36-44; discussion, pages 45-52.

58 miles of 8" oil pipe lines in Oklahoma were examined for pitting, and the pipe line currents and soil resistivities measured. The authors conclude that there is some correlation between long line currents and corrosion. In general, galvanic currents gradually accumulate on pipe lines through soils of high resistance, and in most cases discharge from the lines in soils of low resistance. If current density is relatively high and the discharge is abrupt, deep pitting is usually experienced. They also conclude that there is considerable correlation between depth of pits and resistivity. Soil resistivities of less than 1,000 ohms are usually indicative of severe pitting. The discussion showed considerable disagreement as to the correlation of long line currents and corrosion. VVK (4)

The Deterioration of Structures in Sea-Water. Department of Scientific & Industrial Research. *12th Interim Report of the Committee of the Institute of Civil Engineers*, 1932, 28 pages. Price 6d.

Describes the work carried out during the year 1930-31 by the Committee, which has been investigating since 1916 the deterioration of timber, metal and concrete exposed to the sea. A large number of iron and steel test bars have been exposed for 9 years at 4 stations and the results of the latest periodical inspections are given. Reference is made to researches in the United States. (4)

Wrought Iron Piles Resist Salt Water for 50 Years. O. W. Degen. *Engineering News-Record*, Vol. 108, Mar. 17, 1932, pages 397-398.

Wrought iron piles exposed to sea water in San Francisco Bay for a half century were removed and were found to be in an excellent state of preservation. Inspection showed them to be covered with a protective rust scale tightly adhering to the Fe. CBJ (4)

Corrosion of Malleable Iron. F. W. Wolf & L. A. Meisse *Proceedings American Society for Testing Materials*, Vol. 31, 1931, Pt. 2, pages 422-433.

Keeping White Rust from Zinc-Coated Products. Wallace G. Imhoff. *Iron Age*, Vol. 129, Jan. 21, 1932, pages 232-235.

White rust has been found on practically all kinds of galvanized products. Chemical analysis shows it to be zinc oxide, zinc hydroxide and zinc carbonate. Corrosion products depend on various conditions. Causes and agents of corrosion are air, water, moisture, carbon dioxide, sulphur gases, chemical solutions, etc. Mechanism of formation of white rust seems to proceed first by forming the hydroxide which later changes to zinc oxide and carbonate. White rust formation may be avoided by eliminating as nearly as possible, all conditions that make formation of white rust possible and protection of zinc coating with some kind of air and moisture proof coating. VSP (4)

Pitting of Hydraulic Turbine Runners. ALBERT H. MYERS (Stone & Webster). *Electrical World,* Vol. 99, Feb. 13, 1932, pages 328-329.

Examples of installations that exhibit corrosion pits from spot oxidation and from electrolytic action are noted. The causes and corrective measures are pointed out. One cause is electrolytic action or stray electric currents, and another the faulty or, at times, imperfect design of the turbine runner discharge passages in conjunction with the draft tube. Several illustrations are included. WHB (4)

Prevention of Intergranular Corrosion in Corrosion-resistant Chromium-Nickel Steels. P. PAYSON (Crucible Steel Co. of America). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 464, Feb. 1932, 25 pages.

Reasons for the susceptibility of alloys of the 18-8 type to intergranular corrosion resulting from reheating to temperatures between 1000 and 1600° F. are discussed. An attempt was made to develop alloys that would be resistant to intergranular attack after having been heated for 10 min. in the dangerous range. Experimental melts containing from 0.09 to 0.17% C, approximately 8% Ni and from 18 to 22% Cr were prepared. One series of alloys contained from 0.80 to 4.02% W, another from 0.99 to 3.38% Mo, and a third from 0.66 to 1.88% V. One alloy contained 3.92% Si, another 0.70% Ti and another 0.87% Ti. Samples of each alloy were quenched from 1900 and 2100° F., and the magnetic susceptibility determined. Pieces of the quenched alloys were then reheated for 10 min. periods in the temperature range 1000 to 1600° F., and the susceptibility to intergranular corrosion determined by means of the Strauss solution. The susceptibility to intergranular corrosion did not bear a direct relationship to the magnetic properties. Increasing the Cr to 22% makes the steel resistant to all but the 1100° F. reheating temperature. Small amounts of W, with increased Cr, improved the resistance, but over 0.8% appeared to decrease the resistance. The addition of 1.87% Mo did not better the steel, but 3.3% did. Even 0.17% C with 3.3% Mo was resistant to deterioration when quenched from 1900° F., but less so when quenched from 2100° F. V, Si and Ti have some effect in retarding deterioration. The general subject of intergranular failure is discussed, and it is suggested that some of the addition agents cause the formation of ferrite, and furthermore that the carbides precipitate in this ferrite rather than in the grain boundaries where they may cause intergranular attack. Micrographs are given to prove this point. 8 references. JLG (4)

A Quantitative Method for the Estimation of Intercrystalline Corrosion in Austenitic Stainless Steels. J. J. B. RUTHERFORD & ROBERT H. ABORN (U. S. Steel Corp.). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 9 pages.

The electric resistance was used as a measure of intergranular corrosion. If the material is massive, small specimens ⅛ or ¼" thick and 2 or 3" long should be prepared. Wires or strips can be conveniently used. Samples were corroded by a boiling H_2SO_4-$CuSO_4$ solution containing 15 g. $CuSO_4 \cdot 5H_2O$ and 47 cc. concentrated H_2SO_4 per liter. Samples of ⅛" wire were kept in the boiling solution for 24 hrs. In 18-8 alloys susceptibility to attack was found to increase with the grain size. The effect of various tempering temperatures were studied. The resistance method was found to be very sensitive and to yield quantitative data with respect to the attack. 4 references. JLG (4)

Corrosion Studies of Cold Rolled Acid-Resistant Chromium-Nickel Steel. (Korrosionsversuche an Kaltgewalztem Säurebestandigem Chrom-Nickel-Stahl.) PAUL SCHAFMEISTER & ANDREAS GOTTA. *Archiv für das Eisenhüttenwesen,* Vol. 5, Feb. 1932, pages 427-430.

Tests in 13 and 61% H_2SO_4 made on 2 steel sheets, (1) 8.8% Ni and 17.6% Cr, and (2) 9.9% Ni, 17.1% Cr and 2.8% Mo cold rolled from 2 to 60%, without intermediate anneals. Corrosion resistance of non-rusting and acid-resistant Cr-Ni steels depends on breaking down of its passive protective layer. This passive layer re-forms very quickly, if it is once damaged or at all removed through mechanical or chemical action. Superiority of molybdenum Cr-Ni steel in cold H_2SO_4 is to be accounted for due to its greater tendency to become passive. Cold working without subsequent heat treatment decreases resistance towards acids. DTR (4)

Electrochemical Potentials of Nitrified Steels. SHUN-ICHI SATOH (Mitsubishi Zosen Kaisha, Ltd). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 447, Feb. 1932, 31 pages.

With the object of predicting the effect of nitriding on the corrosion of steels, single potential differences of un-nitrided and nitrided steels were measured. Steels of various analyses, including Cr-Al, Cr-Ti, and Cr-Zr, but not Cr-Al-Mo or Cr-V, were used. The potentials were determined in distilled water, sea water, saturated $CuSO_4$ and normal $FeSO_4$ solutions. After the nitriding treatment the steels that respond to the treatment become about 0.6 volts nobler in distilled water and about 0.2 volts nobler in sea water, but when first placed in $FeSO_4$ solution they are about 0.07 volts baser and finally about 0.03 volts. In saturated $CuSO_4$ nitrided steels had a potential of about +0.2 volts. The potential in $FeSO_4$ is very sensitive to traces of $Fe_2(SO_4)_3$. In distilled water nitrided steels become black, but do not rust to form the red hydroxide. 13 references. JLG (4)

Increasing Corrosion Resistance by Alloying. (Erhöhung des Korrosionswiderstandes durch Legieren.) A. FRY. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

In creating new corrosion-resisting alloys, not only chemical affinity and electrolytic potential must be considered, but also the mechanical and technological properties. Alloying must either increase the chemical stability or procure protective layers in case of corrosion attack. The consequences as to production and application of corrosion resisting alloys resulting from the above requirements are discussed. GN (4)

Corrosion-Resistance of Chromium-Nickel-Iron Alloys. (Korrosions-beständigkeit von Chrom-Nickel-Eisen-Legierungen.) E. WELLMAN. *Zeitschrift für Elektrochemie,* Vol. 37, Mar. 1931, pages 142-156.

Tests on the behavior of a range of Ni-Fe and Ni-Cr-Fe alloys in contact with sulphur dioxide, sulphur dioxide plus air (moist and dry), and sulphurreted hydrogen, hypochlorite solutions (with and without traces of Fe), phenol, tartaric acid and citric acid. The alloys used comprise compositions representative of Ni-Fe alloys, Cr-Fe alloys, alloys containing low Cr and high Ni, alloys of approximately equal Ni and Cr contents, and alloys with low Ni and high Cr. Non-Oxidizing Steels and Corrosion. (Aciers Inoxydables et Corrosion). J. GALIBOURG. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Nov. 1931, pages 547-559.

In the present study, the author examines only the high spots of the corrosion question and gives rapid indications of the characteristics of steels typically involved in this problem of corrosion. As this study is based only on information taken from the literature, it gives as a whole, a clear and complete survey of non-oxidizing alloys. GTM (4)

Rust and Acid-Resisting Steels from the Standpoint of the Chemical Engineer. W. H. HATFIELD (Director, Brown-Firth Research Laboratories). *Industrial Chemist,* Vol. 7, Nov. 1931, pages 435-437.

A short discussion of the advantages of austenitic Cr-Ni (18-8) steel in the brewing, dairy, and dyeing industries, with especial regard to maintaining color and flavor, as well as overcoming contamination. RAW (4)

Wear Resistant Materials for Steam Turbine Blades. (Verschleissfeste Werkstoffe für Dampfturbinenschaufeln.) E. HOUDREMONT. *Stahl und Eisen,* Vol. 52, Jan. 28, 1932, page 88.

Discussion of Ray's paper published in "Power," Vol. 73, 1931, page 804. The writer points out that the materials must be examined not only from the viewpoint of wear resistance but also from the angle of corrosion resistance, vibration resistance, non-sensitivity of the top surfaces, etc. See "Investigation of Materials to Reduce Steam Turbine Blade Wear," *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 6. DTR (4)

Effect of Heat Treatment on Corrosion Resistance of Stainless Iron. CLARENCE G. MERRITT. (Crucible Steel Co. of America). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 18 pages.

It is known that the mechanical properties of the "Chromium Irons" (less than 0.12% C and 11.5 to 15% Cr) are dependent on the heat treatment, but it has been assumed that heat treatment has little effect on the resistance to corrosion. Corrosion, tensile, hardness and impact tests were made on a series of quenched and tempered or rolled and tempered chromium irons. The corrosion resistance was measured by the U. S. Navy sea-salt spray test. On tempering the rolled or quenched alloys at 1000° F. a marked increase in susceptibility to corrosion resulted, while the hardness, impact resistance and proportional limit decreased. Tempering either above or below this temperature does not harm the alloys. The deterioration at 1000° F. was attributed to the precipitation of finely divided carbides. 7 references. JLG (4)

Location and Study of Pipe Line Corrosion by Surface Electrical Measurements. C. & M. SCHLUMBERGER & E. G. LEONARDON (Société de Prospection Electrique, Paris, and Schlumberger Electrical Prospecting Methods, New York). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 476, Feb. 1932, 24 pages.

Previous work and work now in progress on pipe line corrosion is reviewed. Corrosion may occur as: (1) Chemical corrosion, and (2) Electrolytic corrosion in which the attack of the metal pipe is due to stray electrical currents. In either case electrical currents are present and the intensity of these currents can be determined by measurements on the pipe. This method is not always applicable and is usually very expensive. A process was developed whereby the corroding currents could be determined from surface measurements. Methods are described by which the current flowing through the pipe, the conductivity of the ground, and the direction and strength of stray currents can be estimated from surface measurements. By suitable methods the autogalvanic currents can be separated from the stray currents. The depth of the pipe can also be determined from the electrical measurements. A study of the corrosion of a pipe line in a town near Paris is described. It was found that the end of the pipe was being corroded by return currents from a street railway, and this condition was corrected by the installation of a large earth bar at the end of the pipe. 14 references. JLG (4)

Determining the Corrosivity of Soils. E. R. SHEPARD (Bureau of Standards). *Oil & Gas Journal,* Vol. 30, June 4, 1931, pages T-40, T-43.

General discussion of soil corrosion, description of the Shepard soil rod and the correlation of the Putman, Corfield, and Legg tests. The author concludes that the measurement of soil resistivity is the simplest and most satisfactory test available to determine the corrosivity of soils and that such a test may be used as a rough index of the corrosivity of alkaline soils. No electrical test yet devised appears to offer a generally satisfactory index for the corrosivity of acid soils. VVK (4)

The Influence of Alien Metals on the Dissolving Velocity of Base Metals. (Der Einfluss von Fremdmetallen auf die Auflösungsgeschwindigkeit unedler Metalle.) G. TAMMANN & F. NEUBERT. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 201, Dec. 8, 1931, pages 225-244.

The H_2-evolution in the dissolving of metals and their solid solutions in acid was investigated and formulas developed which represent the dissolution velocity and take into account the influence of local elements formed by the presence of foreign metals; a rarer metal always increases the velocity of dissolution. Results for several metals and alloys are given. Ha (4)

The New Observation Methods on Crystal Growth. (Die neuen Beobachtungsmethoden des Kristallwachstums.) E. Herlinger. *Zeitschrift für den physikalischen und chemischen Unterricht,* Vol. 44, July/Aug. 1931, pages 148-159.

A special chapter is devoted to the preparation of single crystals from metals. 66 references. EF (5a)

The Micro-optical Investigation of Non-ferrous Alloys by Polarized Light. M. v. Schwarz. *Metallurgia,* Vol. 4, Oct. 1931, pages 180-186.

The effects of illumination by polarized light in the examination of a number of alloys is described. A Reichert microscope equipped with a polarizer and analyzer was used. Sulphides could be distinguished from oxides in Cu. Non-metallic inclusions and variations in composition in Cu alloys could be detected with polarized light while their detection with ordinary light was, at least, difficult. Polarized light was also advantageous in studying some Al alloys. Many micrographs, including 9 in full color, are shown. Contains 8 references. JLG (5a)

The Diffusion of two Metals into each other during the Formation of an Intermetallic Compound. (Die diffusion zweier Metalle ineinander unter Bilding intermetallischer Verbindung.) G. Tammann & H. J. Rocha. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 199, July 21, 1931, pages 289-305.

If grains of 2 metals are heated and pressed together they diffuse into each other. The possibility is discussed of an experimental decision of the question whether a crystal is in fact of singular composition, or if a series, though limited, of solid solutions exists. For the second case, the diffusion coefficient can be derived from the growth of the crystal, in the first this was not possible. Ha (5a)

Chemistry of Alloys. (Chemie der Legierungen.) A. Westgren. *Die Metallbörse,* Vol. 21, Dec. 9, 1931, page 2107.

Gives an extract of a lecture delivered on Nov. 3, 1931, at Berlin, before 5 combined German technical societies dealing with intermetallic compounds in binary systems. EF (5a)

Crystal Structure and Atomic Properties of Alloys Containing Transition Elements. Arne Westgren. *Journal Franklin Institute,* Vol. 212, Nov. 1931, pages 577-599.

Presented at meeting of Franklin Institute, Feb. 5, 1931. Bibliography of 32 references. Bahr's so-called transition elements consist of the series 21 Sc — 28 Ni, 39 Y — 46 Pd, 57 La — 78 Pt, 89 Ac — 92 U, and they are designated by enclosure in frames in his periodic table. The divergence between transition elements and other metals manifests itself in no less than 3 different ways in their metallic reaction products: (1) The transition elements alone are able to form phases with nickel-arsenide structure; (2) when the transition elements combine with H, B, C, or N, they give rise to reaction products with metallic properties, which is not the case with other elements. Provided the atoms of the transition elements in a phase of this kind are sufficiently big in relation to those of the metalloid, the resultant structure is of a simple kind, of the interstitial type; (3) in combination with Zn, Cd, or Al, at certain proportions, the transition elements give rise to phases having similar structure to β or γ brass. Present experimental results are too incomplete to furnish a coherent idea regarding the conditions prevailing. DTR (5a)

Secondary Structure and Mosaic Structure of Crystals. F. Zwicky. *Physical Review,* Vol. 40, Apr. 1932, pages 63-77.

A brief summary is given of some of the essentials of the theory of the secondary structure. This structure is very sensitive to external distributing effects which frequently cause the transition of crystals from thermally stable into thermally pseudostable configurations for which the terms mosaic structure is proposed. A discussion of the relation of the mosaic structure to the secondary structure is given. It is shown that several very fundamental causes are operative during the growth of crystals which endanger the formation of thermally stable configurations. The most important of these is due to the fact that on solidification the heat of fusion must be carried away from the growing surface. The resulting temperature gradient very often is great enough to produce plastic deformation in the crystals in *status nascendi.* Finally a short review is given which intends to show that the adoption of the conception of a secondary structure and the closely related mosaic structure provides an adequate basis for the understanding of the totality of phenomena which is characteristic for the solid state of matter. The Austenite-Pearlite Transformation and the Transition Constituents. Albert Sauveur. *Heat Treating & Forging,* Vol. 17, Mar. 1931, pages 250-251.

The author discusses the mechanism of the transformation of eutectoid steel from its austenitic to its pearlitic condition as it cools slowly through its thermal critical range. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 161. Ha (5a)

Practical Application of Electro-Chemistry to Modern Macrography. John H. Hruska. *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1034-1037.

Electrolytic method of reproducing macrostructures is due to A. Glazunov. A fairly smooth section of the specimen is connected to the positive pole of a direct current and a sheet of unsized paper, soaked in a suitable electrolyte, is applied to the surface. The paper is laid on a plate of another metal free from oxides or corroded spots. Stainless steel is a suitable material. The plate is connected to the negative terminal. Ions liberated from the specimen pass into the electrolyte of the paper. If the solution is such that colored precipitates are formed, then an electrolytically deposited image of the specimen will be obtained. If the sample is homogeneous, the paper becomes uniformly colored. Heterogeneities produce marked differences in coloration. To obtain good results, electrolyte paper should not be extremely "wet" and unduly high concentrations of electrolytic solutions should be avoided. Voltage for ferrous metals should not exceed 2.5 volts; time of electrolysis should be from 10 secs. to 2 mins. For larger samples, several sheets of soft paper soaked in 5% NaCl solution and placed under the electrolyte paper will aid in obtaining a uniform coloration. Most generally used electrolyte for ferrous metals is 3-5% aqueous solution of $K_4Fe(CN)_6$. Table shows electrolytes used successfully for non-ferrous metals.

Metal	Electrolyte	Coloration	Remarks
Bi	KI	Dark grayish yellow	
Co	KNO_2	Greenish yellow	
Cu	$K_4Fe(CN)_6$	Red	
Pb	KI	Golden yellow	
Ni	$(CH_3)_2C_2(NOH)_2$	Rose	
Ag	$K_2Cr_2O_7$	Reddish brown	
Zn	$K_4Fe(CN)_6$	Pure white	Dark or black paper to be used

The author has developed an easily built, self-contained apparatus, comprising electrical equipment, compartment for electrolyte and salts, drawer for paper, tray for soaking and metallic plate with suitable electrical connection. The electrolytic method is of great practical value in reproducing macrostructures with delicate details. Non-metallic inclusions will appear as white spots on the paper. Neither mechanical nor thermal treatment affect the resulting prints. MS (5a)

The Lead-Zinc Eutectic. J. M. Hodge & R. H. Heyer (Purdue University). *Metals & Alloys,* Vol. 2, Nov. 1931, pages 297-301.

The authors present a microscopic and thermal study of alloys of Zn and Pb. The eutectic composition was found to be 0.50% Zn and 99.5% Pb, the eutectic temperature 318.2° C. Evidence is presented that Zn has a solubility of 0.05-0.06% in Pb. The hardness of these alloys was studied and it was found that Zn as the eutectic imparts a greater increase in hardness than as plates in the hyper-eutectic alloys. Micrographs show the structures studied and the technique of making the thermal study is described. WLC (5a)

The Effect of Slag Composition upon the Structure of Grey Cast Iron. E. Diepschlag & L. Treuheit. *Foundry Trade Journal,* Vol. 46, Jan. 7, 1932, page 5.

Extended abstract of an article which appeared in *Die Giesserei* (1931, 18, pages 705-710). See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 7. OWE (5a)

Crystal Structure and Disintegration of Lead. (Kristallgefüge und Disglomeration des Bleies.) Otto Haehnel. *Elektrische Nachrichten der Technik,* Vol. 8, Feb. 1931, pages 77-78.

Pb cast and cooled in a normal way possesses crystal grains of an average diameter of 8 mm. This refers to Pb of 99.997% purity, but the addition of 1, 2, or 3% Sn has little effect on the grain-size. The addition of 1% Bi reduces the grain-size by 2/3, 1% Sb reduces it by ¾, and 1% Zn, or 0.1% Cu reduces it by ⅞. The grain-size of the metal in Pb-covered cables also varies with the purity of the Pb—the largest grain-size is found in the purest metal, but other factors in the pressing operations may affect the grain-size, such as the rate of cooling after Pb leaves the press. Grain-growth of commercial Pb which has been cold-worked proceeds, in the absence of vibration, only very slowly at 18°-20° C., and is scarcely noticeable in a man's average lifetime. Increase of temperature, however, greatly hastens the rate of grain-growth. Sn 1/3% and Sb 1% or Cu 0.1% reduces the tendency for grain-growth to occur in worked Pb. The disintegration of Pb is not a direct result of the large size of the crystal grains, but coarsely crystalline Pb is more liable to disintegrate under the influence of vibrations set up, for example, in lead-covered cables, especially if the conditions are such that the temperature of the cable may be as high as 40° C. Such conditions would also cause failure of lead alloys as well as of pure lead. WHB (5a)

Crystallization of Copper from Molten Copper Chloride. (Die Kristallisierung des Kupfers aus geschmolzenem Kupferchlorür.) V. Sikvonen. *Zeitschrift für Elektrochemie,* Vol. 37, Feb. 1931, pages 80-82.

It was found that the crystallization of Cu from molten copper chloride in presence of metallic Cu takes place according to the thermic equilibrium dislocation of the system Cu-Cupro ions-Cupric ions, $2\ CuCl \rightleftharpoons Cu + CuCl_2$; the Cu precipitates in the colder parts of the molten salt. The Structure of Ferromagnetic Ferric Oxide. J. Thewlis. (National Physical Laboratory.) *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science, Series* 7, Vol. 12, Dec. 1931, pages 1089-1106.

Theoretical study. Ferromagnetic Fe_2O_3 has a cubic structure. Several references in the footnotes. RHP (5a)

A Critical Point of Zirconium. (Ueber einen Umwandlungspunkt des Zirkons.) R. Vogel & W. Tonn. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 202, Dec. 24, 1931, pages 292-296.

From a series of heating and cooling curves it was found that Zr has a transformation point at 862° C. which is connected, at cooling with a dilatation at heating with a contraction; the length of a Zr rod was changed at this point by 0.072% and its volume 0.22%. Below 862° C. there exists the known stable hexagonal α-zirconium, above 862° C. a stable and denser β Zr. Photomicrographs of the structure are reproduced. Ha (5a)

Segregation of Cementite From Austenite. ROBERT F. MEHL, CHARLES S. BARRETT & DANA W. SMITH. *Nature*, Vol. 129, Feb. 27, 1932, pages 313-314.

The formation of new phases in alloys by precipitation from solid solutions has recently been studied extensively. These studies have given experimental evidence indicating that when a precipitate forms as plates within a crystalline grain, the crystallographic plane to which the plate lies parallel is determined, not only by the lattice structure of the parent solid solution, but also by the lattice structure of the precipitate. If, as Hanemann and Schröder suggest, the formation of Widmanstätten figures—figures of segregation —in hypo- and hyper-eutectoid Fe-C alloys is determined only by the diffusion mechanism characteristics of interstitial solid solutions such as austenite, the Widmanstätten figure obtained in Fe-Ni alloys (meteorites) in which the solid solutions are purely substitutional in type should be radically different, yet the Widmanstätten figures in hypo-eutectoid Fe-C alloys and in meteorites are crystallographically analogous. Furthermore, if diffusion conditions alone determine the type of figure, it would be expected that all Widmanstätten figures formed by precipitation from solid solutions of one basic metal would be identical in form, yet the precipitation of the γ-phase from the Al-rich terminal solid solution in the Al-Ag system leads to the formation of plates parallel to the (111) plane, that of the $CuAl_2$ phase from the Al-rich terminal solid solution in the Al-Cu system forms plates parallel to the (100) plane, and that of the precipitate from the Al-rich solid solution in the Al-Mg-Si system forms plates parallel to the (100) and (110) planes. Although doubtless diffusion conditions affect the external form of a segregate from solid solutions somewhat, it seems certain that the external form taken by the precipitate and the orientation of the lattice of the precipitate are largely determined by crystallographic relationships existing between the 2 participating phases. The Microscope as a Practical Aid in the Cast Iron Foundry. ROY M. ALLEN. *Transactions & Bulletin American Foundrymen's Association*, Vol. 3, Feb. 1932, pages 733-826.

The paper deals with the use of the microscope in studying cast iron and is followed by a detailed discussion of the structural constituents in various types of iron. An appendix gives general instructions on the use of the microscope. See also *Metals & Alloys*, Vol. 2, Aug. 1931, page 142. CHL (5a)

Variations in Microstructure Inherent in Process of Manufacturing Extruded and Forged Brass. OGDEN B. MALIN (Pennsylvania State College). *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 9 pages.

Bibliography of 27 references. Part of a thesis on file at the college. Studied 60-40 leaded brass rod extruded at 1450° F. The front end of the extruded section had a coarser structure than the rear end. The same difference, but to a lesser degree, existed in the forgings made from the extruded rod. The front portions of long forgings also had the coarser structure. JLG (5a)

The Aluminum-Manganese System of Alloys. A. J. BRADLEY & PHYLLIS JONES. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Ser. 7, Vol. 12, pages 1137-1151.

Previous work is limited due to the difficulty in working with these alloys. The present investigation uses the X-ray powder method of investigation. Seven different phases are found and are summarized in the form of a preliminary equilibrium diagram. RHP (5a)

Babbits with Tin Base and Low Antimony and Copper. A. M. BOCHVAR & S. I. IRODOFF. *Tsvetnuie Metallui*, Sept. 1931, pages 1139-1147.

Alloys belonging to the Sn rich region of the ternary system Sn-Sb-Cu were prepared and studied microscopically. Below 6-8% Sb, the hard cubic β-crystals (solid solution of Sn and Sb) are absent; the soft ground mass consists of solid solution of Sn and Sb in which hard crystals of solid solution of Cu and Sn are embedded. The hardness of such alloys is somewhat lower than that of the alloys with higher Sb content (Charpy, 5-6% Cu; 10-12% Sb). Hardness measurements made at different times after casting showed that the alloys are practically non-aging. BND (5a)

The Constitution of Tellurium. K. T. BAINBRIDGE. *Physical Review*, Vol. 39, Mar. 1932, page 1021.

The isotopic constitution of Te has been determined by the method previously described. The work of Aston has been confirmed and extended. Additional isotopes of mass numbers 124, 123 and 122 were found with indications of an extremely faint isotope at 127. WAT (5a)

Structure & X-Ray Analysis (5b)

An X-Ray Camera for Powder Diagrams at Any Temperature. NELSON W. TAYLOR. *Review of Scientific Instruments*, Vol. 2, Nov. 1931, pages 751-755.

A cylindrical X-ray camera of about 57 mm. diameter has been designed which may be used for powder photographs (Hull-Debye-Scherrer method) up to 1000° C. or down to liquid air temperatures. Convenience in use is obtained by placing the film on the outside rather than the inside. Using a Siegbahn type X-ray tube with Cu or Fe anticathode and 15 to 20 milliamperes tubes current, good diagrams may be obtained in 10 mins. to 2 hrs. depending on the substance being investigated. The method permits the study of those crystal modifications which are stable at high or low temperatures but unstable at room temperature. Lattice constants may be determined to an accuracy of 0.2%. WAT (5b)

On a Method to Detect Inner Stresses (Ueber ein Verfahren zum Nachweis innerer Spannungen). F. WEVER & H. MÖLLER. *Archiv für Eisenhüttenwesen*, Vol. 5, Oct. 1931, pages 215-218.

Report of the Kaiser Wilhelm Institut für Eisenforschung. The physical principles of a simple method are described which permits the detection of hidden inner stresses by means of the X-ray Spectroscopy. A cobalt K radiation is used for the examination of the material to be tested. Simple mathematical relations exist between the deformations as detected by the X-rays and the stresses which have brought about the deformation. In order to determine the accuracy of the method, some preliminary tests have been performed. Stresses of a known amount were artificially caused in sheet strips by means of a small bending device. After it had been ascertained that the error does not surpass an upper limit of approximately 0.0001 A.U. units or 3.5×10^{-5} mm. more tests were made which showed that elastic stresses can be determined with an accuracy of $\pm$ 5 kg./mm.[2] It is not yet proven if this method, which has been developed on carbon steels, can also be applied for alloy steels. GN (5b)

X-Ray Analysis of the Gold-Tin Alloys (Röntgenanalyse der Gold-Zinn-Legierungen). S. STENBECK & A. WESTGREN (University of Stockholm). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 14, Sept. 1931, pages 91-96.

The previous work done on the subject is briefly summarized in the introduction. The author's own investigation, achieved with Phragmen's modified X-ray camera and the Fe-K radiation, led to the discovery of a new phase β between 12 and 16 atomic % Sn, showing an hexagonal close-packed arrangement. The existence of 6 different phases in summary could be definitely proven in the Au-Sn system including the following intermetallic compounds: Au-Sn, $Au\text{-}Sn_2$, $Au\text{-}Sn_4$. The atomic structure of Au-Sn corresponds to a nickel-arsenide type pattern. ($a_1 = 4.314$ A.U. and $a_3 = 5.512$ A.U.) The powder photograms of $Au\text{-}Sn_2$ and $Au\text{-}Sn_4$ yielded a wealth of lines indicating a rather complicated structure. EF (5b)

X-Ray Examination of the Lattice Structure of the ϵ-Phase in the Copper-Tin System. (Röntgenographische Untersuchung der Gitterstruktur der ϵ-Phase im Cu-Sn-System.) J. O. LINDE. *Annalen der Physik*, Vol. 8, 1931, Series 5, pages 124-128.

The ϵ-phase of the Cu-Sn system with about 25 atomic % Sn has, in comparison with analogous phases, a very high electrical conductivity. According to a general law stated by Borelius, such phases should have a regular distribution of both kinds of atoms in the lattice. The author finds in the röntgenograms of ϵ-Cu-Sn numerous superstructure lines besides those due to the already known hexagonal lattice with 2 atoms in the elementary cell. These new lines are attributed to a hexagonal lattice having 16 atoms in the elementary cell and a and c axes twice as great as those of the original cell. Further elucidation of the atomic arrangement was not possible from the photographs obtained. Ha (5b)

On the Question of Allotropy of White Tin and the Equilibrium Diagram of the System Tin-Cadmium. YOSIHARU MATUYAMA. *Scientific Papers Institute Physical and Chemical Research, Abstracts*, Tokyo, Vol. 16, Aug. 1931, page 67.

An allotropy of white tin or that of Sn at a high temperature has often been assumed as existing but no positive evidence has yet been found. The author studied this problem by means of several physical methods of high sensitivity, i.e., by measurements of electrical resistance, thermal expansion, thermo-electromotive force, thermal analysis, X-ray analysis, etc. The conclusion was that such a modification of Sn does not exist. The equilibrium diagram of the system Sn-Cd was revised on the tin side. Ha (5b)

Accurate Determination of the Lattice Parameter of As_2O_3 (Präzisionsbestimmung der Gitterkonstante von As_2O_3.) F. LIHL. *Zeitschrift für Kristallographie*, Vol. 81, Jan. 1932, pages 142-147.

The evaluation of 3 Debye- Scherrer patterns gave for the lattice parameter of the cubic face-centered As_2O_3: $a = 11.0457 \pm .0002$ A.U. The density is 3.877. 2 references. GN (5b)

Why Crystals Exist. F. ZWICKY. *Proceedings National Academy of Science*, Vol. 17, 1931, pages 524-532.

The following scheme was proposed in order to understand the relation between structure-sensitive and structure-insensitive properties of the crystalline state. (1) The ordinary cohesive forces whose action radii are of the same order of atomic dimensions are responsible for the condensed states of matter, but are not characteristic for the crystalline state. (2) Transition from the liquid to the crystal can only be effected by the simultaneous coöperation of a great number of atoms in regard to a definite directional arrangement. (3) Several directional phenomena which depend on the coöperation of many particles are discussed briefly. (4) The coöperation phenomenon which is responsible for the stability of a certain crystal will not, in general, have the same symmetry character as the primary structure. It follows that the crystal as a whole cannot be represented by an ideal crystallographic lattice. A secondary structure must be introduced. The peculiar coexistence of perfection and imperfection which is found in most crystals can easily be derived. WAT (5b)

The Structure of Crystals. RALPH W. G. WYCKOFF. American Chemical Society Monograph. 2nd Edition, Chemical Catalog Company, Inc., New York, 1931. Cloth, 6 x 9 inches, 497 pages. Price $7.50.

Since the appearance of the first edition of this book, many important advances have been made in X-ray crystal structure analysis. The new edition, while covering essentially the same topics, has been largely re-written. Part I deals with methods of crystal analysis. The production and properties of X-rays are treated more fully than in the previous edition. The modern gas tube is discussed. The securing and interpretation of data is treated quite largely from the viewpoint of determining the precise atomic arrangement in selected samples. The metallurgist will find little discussion of X-ray diffraction as a laboratory tool for such purposes as the study of recrystallization or preferred orientation. Part II gives the results of crystal analysis arranged largely by structure types. The list of materials is quite inclusive, though the results are, of course, condensed. In all cases, however, references to the literature are given. Alloy systems are treated only in a bibliography, though certain definite intermetallic compounds are described. The book closes with a large, excellently arranged bibliography. This covers a much wider field than the book, and should prove valuable to the metallurgist. There are a large number of new figures, especially in the second part. The index is adequate. H. W. Russell (5b)-B-

Artificial Disinteregration by α-Particles. J. CHADWICK & J. E. R. CONSTABLE. *Proceedings Royal Society*, Vol. 135A, Feb. 1932, pages 48-68.

The protons liberated from Al when bombarded by α-particles from polonium have been examined. It has been found that these protons can be divided into 2 groups. The results are explained on the assumption that the α-particles can enter the nucleus through certain resonance levels. To explain the distintegration of Al it is necessary to assume that there are 4 of these levels. The positions and widths of these resonance levels can be deduced from the experimental results. WAT (5b)

Solid Solutions of Lead and Tin in Bismuth. ERIC R. JETTE & FRANK FOOTE. *Physical Review*, Vol. 39, Mar. 1932, pages 1018-1020.

Bi with maximum impurities totalling 0.046 including 0.01% each of Pb, Ag and S; Pb with maximum impurities of heavy metals 0.10%; and Sn containing 0.10% Pb were used in the determinations. There is a slight but measurable change in the Bi lattice when the saturated solutions of Pb or Sn in this metal are formed. The most striking fact is that the *a* axis decreases and the *c* axis increases which would thereby increase the inisotropy of the metal. This fact is possibly of importance in connection with the magnetic anisotropy discussed by Goetz and Fock, who found that differences existed in the atomic radii of single crystals of Bi and its alloys with Sn and Pb. It is somewhat surprising that both Sn and Pb which have respectively smaller and larger radii than Bi should both affect the Bi lattice in the same way. The volumes of the unit hexagonal prisms are Bi 210.83 = 0.07A³, Bi-Pb 210.85 = 0.11 and Bi-Sn 210.58 = 0.07. The decrease in the volume in the Bi-Sn case seems significant and in the right direction. The Bi-Pb results are inconclusive. These results are presented for their interest in connection with the problem of the magnetic properties of these substances but it is by no means even suggested that the slight variations observed in the lattice constants can account for the whole of the variations in the magnetic properties. WAT (5b)

Thermal Analysis of the System: Lithium-Silver. (Analisi termica del sistema litio-argento.) S. PASTORELLO. *Gazzetta chimica italiana*, Vol. 61, Jan. 1931, pages 47-51.

The system: Li-Ag has already been studied by X-rays. In the present work the same experimental method was used as in the thermal analysis of the system: Li-Ag, and the alloys were prepared in the same way. The following data give the atomic % Li in the alloy, the initial fusion point and the eutectic arrest of the temperature-% composition curve respectively: 0, 961°, —; 0.350, 943°, —; 0.801, 893°, 610°; 1.20, 820°, 610°; 2.10, 700°, 610°; 2.90, 670°, 610°; 4.01, 830°, 610°; 5.90, 950°, —; 8.78, 850°, 410°; 11.8, 623°, 410°; 12.6, 410°, 410°; 16.4, 450°, —; 20.4, 413°, 180°; 26.5, 370°, 180°. These data show the existence of 2 intermetallic compounds, $AgLi_3$, m. 450°, and AgLi, m. 955°. Three eutectics at 610°, 410° and 180° correspond to concentrations of 30, 70 and 100% atomic % Li, respectively. The last 2 eutectics at 180° preclude the existence of other intermetallic compounds or of solid solutions between the components. The alloys containing a high % Ag, i.e., above AgLi, were very ductile. To dispel doubt that might arise about an exact analogy between Ag-Li and Ag-Mg compounds because of the structural difference between Li and Mg, the crystal structure of Li-Al compounds (already known thermally) was studied by X-rays. Thus a Li-Al alloy of the composition LiAl, studied thermally by Müller (*Zeitschrift für Metallkunde*, Vol. 18, page 231) had, as evidenced by X-rays, not only the same structure as LiAg but also nearly the same lattice constant (3.23 A. U. for LiAl and 3.225 for LiAg). This agrees with fact Ag and Al have almost the same at. diam. (2.88 and 2.87 resp.) Ha (5b)

The Beta Transformation in Copper-Zinc and Silver-Zinc Alloys. (Ueber die Beta Umwandlung in Kupfer-Zink und Silber-Zinklegierungen. I.) M. STRAUMANIS & J. WEERTS. *Metallwirtschaft*, Vol. 10, Dec. 4, 1931, pages 919-922.

19 references. A Ag-Zn alloy containing 50 atomic % Ag was examined by means of X-rays at temperatures up to 550° C. The samples were in sheet form and were heated by means of a salt bath. The lines of the body centered cubic lattice of quenched β Ag-Zn alloys disappear at about 300° C. It is probable that the β transformation in brass is accompanied by a change from the orderly to the disorderly atomic arrangement at higher temperatures. In contrast to β brass, the transformation of β Ag-Zn alloys continues between 100° and 225° C. to the formation of a new phase This phase has a low symmetrical lattice structure and is designated γ. It is formed by a regular change of the body centered cubic lattice which apparently is reversible up to a certain point. Preliminary information about the transformation has been obtained from microscopic examination, hardness tests and X-ray photographs and the studies are being continued. CEM (5b)

Structure of Rolled Zinc. (Bemerkungen zur Walztextur von Zink.) M. A. VALOUCH. *Metallwirtschaft*, Vol. 11, Mar. 18, 1932, pages 165-166.

5 references. A piece of rolled sheet Zn. 3 mm. thick was reduced to .03 mm. by etching. X-ray photograms were taken in 14 directions and from these the pole figures of the base, the prism plane and the pyramid plane were constructed. Results compared with other investigators. CEM (5b)

Examination of Steel Structures by Gamma Rays has many Advantages. *Steel.* Vol. 89, Dec. 21, 1931, page 36.

On the Quantitative Determination of Retained Austenite in Quenched Steels. K. TAMARU & S. SEKITO. *Kinzoku no Kenkyu*, Japan, Nov. 1931, pages 595-607; *Science Reports Tohoku Imperial University*, Series 1, Vol. 20, 1931, pages 377-394.

The quantity of retained austenite in quenched steels was determined by means of X-ray analysis as well as by measuring their magnetic saturation values. In the X-ray analysis, the specimen was a thin rod, 5 mm. in diameter, on which a thin strip of gold had been longitudinally fixed, and the X-ray photographs were taken with the specimen rotating. An austenitic Mn steel specimen was also treated in the same manner. The intensity of the line of austenite in Mn steel was taken as a standard and the retained austenite in quenched steels of different C content was determined. The same results were obtained by the 2 methods, i.e., the measurements by X-ray analysis and by saturation magnetization, as in the following: for a steel of a given C content, the quantity of the retained austenite increases; reaches a maximum at about 1000° C.; then decreases as the quenching temperature is raised. The quantity of retained austenite is greater in case of oil-quenching than in that of water-quenching. The cause for this is said to be the accelerating effect of the thermal stress during quenching on the austenite $\rightarrow$ martensite transformation. In quenched specimens, when cooled in liquid air, the quantity of retained austenite is diminished. The residual austenite of a steel, containing 0.89% C., 4-5 mm. diam., quenched at 1000° C., is transformed to martensite when cooled in liquid air by about 1/3 in oil-quench and about ¼ in water-quench. KT (5b)

Spectroscopy of X-Rays. (Spektroskopie der Röntgenstrahlen.) MANNE SIEGBAHN. Second revised edition. Julius Springer Verlag, Berlin, 1931. Paper, 6½x9½ in., 574 pages. Price 49.60 RM.

No book could be more welcome than the entirely new edition of this great classic in the field of X-ray spectroscopy, or what may be termed the physics of X-rays. It would be expected that other branches of X-ray science such as the examination of materials would display far greater change in the course of more than eight years than the fundamentals of X-ray spectroscopy but as a matter of fact, progress in this field has been so great that the book has been entirely rewritten. The chapters present the following subjects: Short summary of the knowledge of X-rays up to the time of the von Laue, optics of X-rays, technique of X-ray spectroscopy, emission spectra, absorption spectra, the systemization and theory of X-ray spectra, extension of spectra to longer wave lengths, and the continuous X-ray spectra. Siegbahn has given, as would be expected, a remarkably complete survey of modern apparatus which has made possible the marvelous accuracy in measurement of wave lengths. Approved values for these wave lengths are given in full in extended tables. The theoretical treatment in terms of atomic structure is perhaps the only disappointing feature. The author has been confronted with the inadequacy of the Bohr theory which, of course, was a basis for theoretical discussion in the first edition and at the same time has been faced with the necessity of trying to relate experimental data with the modern quantum theory. Probably the very best presentation possible has been given when the uncertain status of present theories of atomic structure is taken into consideration. The laws of X-ray spectra are presented in terms of energy levels without any attempt to visualize any process within the atom or any structure of the atom beyond the usual equations. Naturally this presents more difficult reading than the theory as it existed in 1923. However, this volume must be considered always as one of the great classics in the field of X-ray science since the author is unquestionably the outstanding authority. Anyone interested in any modern phase of the science necessarily must have a copy of this book directly at hand. The book is excellently printed and bound and is practically entirely free from error. Studies upon the Widmanstätten Structure, III.—The Aluminum-rich Alloys of Aluminum with Copper, and of Aluminum with Magnesium and Silicon. ROBERT F. MEHL, CHARLES S. BARRETT & FREDERICK N. RHINES. *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 26 pages.

The methods of investigation were similar to those described in earlier papers (*Metals & Alloys*, Vol. 1, Dec. 1930, page 908; Vol. 2, June 1931, page 111). In the low-Cu alloys plates of $CuAl_2$ precipitated on planes of the form (100) in the parent solid solution. The precipitate was quite definitely in the form of plates and not needles. In the high Cu alloys (up to 6%) particles of the compound were also formed on planes of higher indices, but it was not possible to determine the form of the planes. Efforts to determine the orientation of the plates of $CuAl_2$ were unsuccessful, but some indication that the basal plane of the compound was parallel to the (100) plane of the solid solution was obtained. Alloys containing as much as 2% Mg_2Si were studied. In this system plates were precipitated on both the (100) and the (110) planes. In general, those on the (100) planes were thinner and longer than those on the other family of planes. Etching tests indicated that the precipitate was probably not Mg_2Si; it etched like Al_3Mg_2. X-ray diffraction patterns also indicate that it was probably Al_3Mg_2 rather than Mg_2Si. The same compound was precipitated in both planes. It is therefor suggested that age-hardening in Al-Mg-Si alloys is due to the Al-Mg compound, and not to Mg_2Si. The mechanism of formation of $CuAl_2$ is discussed. It is suggested that the (001) plane in $CuAl_2$ is parallel to the (100) plane in the Al matrix, and that the [110] direction in $CuAl_2$ is parallel to the [120] direction in the solution. 13 references. PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

The Resistance to Wear of Carbon Steels. SAMUEL J. ROSENBERG. *Bureau of Standards Journal of Research*, Vol. 7, Sept. 1931, pages 419-428, *Research Paper* No. 348.

A study was made of the effect of heat treatment and C content upon the wear-resistance of C steels as determined by the Amsler machine (combined rolling and sliding friction under heavy pressures). See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 37. WAT (6)

Magnetic Analysis of Steel. *Electrical Review*, Vol. 109, Dec. 18, 1931, page 910.

Describes system developed by the Magnetic Analysis Corporation, New York. Two magnetizing coils having primary windings of the same number of turns are connected in series. A standard bar of steel, of similar section to that to be tested, is placed in the center of one coil and is inclosed in a tubular chamber, through which running H_2O is passed to prevent overheating by eddy currents. Bars to be tested are passed slowly through the center of the other coil by means of a motor-driven feed mechanism. There is a secondary search coil inside of each main coil, which can be changed to suit the size and shape of the bar to be tested. These coils are connected in series, but opposed to the primary coils so that induced currents tend to neutralize each other. The secondary coils are connected to the galvanometer of a visible type oscillograph. Gives typical curves obtained in testing various steels. Process is at present limited to mild-steel bars up to 2" diameter and alloy steels up to 3". MS (6)

The Change of Volume in Steel Produced by Deformation. *Metallurgist*, Apr. 1931, pages 53-54.

Physical Tests for Cast Iron. JOHN SHAW. *Iron & Steel Industry*, Vol. 5, Oct. 1931, pages 3-7.

The need for simple International testing specifications is shown. Weak points in present testing methods are pointed out in that: strength values fall off as the center of a cast bar is approached in machining samples and shear values bear no constant ratio to tensile values so that as tensile values drop, shear values reach a point at which castings are passed which would be condemned by tensile or transverse tests. Objections to British specifications are given and a machine is recommended for testing shock resistance. CHL (6)

An Oscillation Method for Investigating the Strength of Crystals. (Über eine Schwingungsmethode zur Untersuchung der Kristallfestigkeit.) W. D. KUSNETZOW & E. W. LAWRENTJEWA (Physico-Technical Institute of Tomsk) *Zeitschrift für Kristallographie*, Vol. 80, Sept. 1931, pages 54-62.

A pendulum, having a steel prism at its lower end is placed on the crystal surface and the equilibrium is upset. The damping effect of the amplitudes is observed and taken as a measure of the crystal's hardness or strength. Tests correlating the crystallographic structure and chemical composition to the hardness disclosed: (1) the strength of the crystals increases with decreasing ion distances and increasing ion charges; (2) in the same series of salts, for instance in Ag-halides, the strength changes abruptly at the transition of the different space groups; (3) the strength of crystals secured from solutions is lower than the strength of crystals obtained from melts; (4) the damping of the same crystal proved to be dependent on the direction of oscillation. The Method of Damped Vibrations for the Determination of Hardness. W. D. KUZNETZOV. *Zhurnal Prikladnoi Fiziki* (*Journal Applied Physics*), Vol. 6, No. 1, 1929, pages 33-44.

The method consists in placing the point of the pendulum on the specimen to be tested, deflecting the pendulum to a definite amplitude, and noting the time **T**, or the number of vibrations N, in which the amplitude is reduced by a definite amount. The values of T and N are measures of the hardness. The oscillation period, in practice, is independent of the damping. The hardness series of metals obtained by this method coincides with that obtained by the scratch method. WHB (6)

Experiments on the Determination of the Buckling Stresses of Various Structural Steels. (Versuche zur Ermittlung der Knickspannungen für verschiedene Baustähle.) L. ILOSVAR. *Montanistische Rundschau*, Vol. 24, Feb. 16, 1932, pages 15-16.

The paper summarizes the principal results of investigations by W. Rein on the above subject. (W. Rein, *Berichte des Ausschusses für Versuche im Stahlbau*, Report 4, published by Julius Springer, Berlin.) GN (6)

On the Change of the Modulus of Rigidity in Different Metals. T. KAWAI. *Kinzoku no Kenkyu*, Japan, Jan. 1932, pages 38-56: *Science Reports Tohoku University*, Vol. 20, 1931, pages 681-709.

The change of the modulus of rigidity due to cold-working, such as stretching and drawing, was determined for various metals. A torsion testing machine was specially designed for the present work which can measure a torque accurately up to 600 mm. Kg. For measuring the angle of twist of the test piece, two small clips with mirrors are fastened to the test piece, and the rotation of each mirror is measured by a telescope. In Al and brass, the rigidity always decreases by cold-working; in Cu it decreases, till a minimum is reached after which the amount of decrease gradually diminishes with an increasing degree of cold-working; in Ni the rigidity increases rapidly at first but after reaching a maximum it decreases gradually. The relation between the annealing temperature and the modulus of rigidity was determined for cold-worked Cu, Al and Ni. In Cu and Al the rigidity first increases gradually, then rapidly from a temperature where recrystallization begins to that at which recrystallization is completed, and after reaching a maximum the rigidity decreases with a rising temperature. In Ni the rigidity increases gradually up to the beginning of the recrystallization temperature, after which it decreases rapidly up to 700° C. and then slowly decreases. At 800° C. it recovers almost completely the value it had before cold-working. The change of the modulus of rigidity caused by cold-working was determined for Swedish iron, Armco iron, mild steel (0.10% C, 0.20% C and 0.39% C). The rigidity slightly decreases at first, reaches a minimum and afterwards increases. The effect of annealing on the modulus of rigidity of cold-drawn mild steel also was investigated. The rigidity increases gradually up to the annealing temperature, where recrystallization begins, that is 450° C., and then rapidly decreases up to 600° C. Above this temperature, the change is gradual and at 900° C. the rigidity recovers almost completely the value it had before cold-working. The above change of the modulus of rigidity caused by cold-working may be explained as the combined effect of three factors, that is, internal stress and rotation of crystal grains, both of which make the rigidity decrease, as well as the refining of the grain size which increases the rigidity. KT (6)

Magnetostrain and Magnetoresistance. L. W. MCKEEHAN. *Physical Review*, Vol. 38, Jan. 1932, pages 368-371.

The paper is one of those presented in a Symposium on Magnetization by the American Physical Society, Sept. 1931. The dimensions and electrical conductivities of a ferromagnetic body are affected in two ways by its magnetization. The conspicuous effects at temperatures far below the Curie points are anisotropic. The anisotropic magnetostrains are most apparent in single crystal specimens. With reference to the direction along which the magnetization increases the longitudinal and transverse effects are opposite in sign. The longitudinal magnetostrain may be positive or negative depending upon the material. The longitudinal magnetoresistance is always positive. The conspicuous magnetostrains and magnetoresistance at or near the Curie point are apparently isotropic. The isotropic magnetostrain may be of either sign. The isotropic magnetoresistance is negative, that is, the resistance increases as the magnetization diminishes with rise in temperature. WAT (6)

The Graphic Calculation of Transverse Strengths. R. MITSCHE. *Foundry Trade Journal*, Vol. 45, Nov. 12, 1931, page 307,

An extended abstract, accompanied by 4 diagrams, of an article which appeared in *Die Giesserei* (1931, 18, 246). See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA9. OWE (6)

The Evaluation of the Bending Test in Cast-Iron. (Zur Auswertung des Biegeversuchs bei Gusseisen.) G. MEYERSBERG. *Krupp'sche Monatshefte*, Vol. 12, Dec. 1931, pages 301-330.

The particular suitability of the bending test for judging the quality of a cast-iron is explained and the nature of the process analyzed and definitions given. For the characterization of a material only those properties should be used which are independent of chance values which is expressed in dispersion of test values when plotted. The bending test conforms to this requirement. The magnitude of permanent deflection can be estimated from the shape of the bending curve, and the latter can be derived from the elastic line. In order to make possible a clear definition and comparison of different types of cast-iron a diagram is suggested which shows the tensile strength as abscissa and the bending number as ordinate; further are the "isoflexes" to be drawn in this diagram, that is the curves of equal bending product. The practical application of this diagram is explained. Ha (6)

The Faraday Effect in Ferromagnetics. H. R. HULME. *Proceedings Royal Society*, Vol. 135A, Feb. 1932, pages 237-257.

The rotation of polarized light transmitted through very thin films of ferromagnetics is discussed, using the ordinary simple model for a ferromagnetic. Owing to the importance of the exchange forces, each atom cannot be treated separately, but a fraction of the crystal containing a large number of atoms must be taken as a unit. For such a system are found approximate values for the possible wave-functions in the ground states when one quantum of light has been absorbed. This enables the energy changes and the matrix elements of the polarization for those (virtual) transitions occurring in the dispersion formula to be found. Owing to spin-orbit interaction in the excited states, these dispersion formulae are slightly different for left and right circularly polarized light. The indices of refraction are therefore different and a beam of plane polarized light suffers a rotation. With the very rough model used it was only possible to obtain the order of magnitude of the rotation. This is reproduced by the calculations presented, and for magnetization in the region of saturation it is found that the rotation is proportional to the magnetization, and increases with the wave-length of the light. Both of these results are experimentally true. WAT (6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A.S.T.M. Research Committee on Fatigue of Metals.

Torsional Fatigue Tests of Cold-Drawn Wires. F. C. Lea & J. Dick. *Proceedings Institution of Mechanical Engineers,* Vol. 120, May 1931, pages 661-677.

Experiments were made with special machines which assure the breaking clear of the grips. Hard drawn, and quenched and tempered wires show a 20% greater safe range of torsional repeated stresses when the break is clear of the grips. Surface grinding of samples increases the fracture range 50%. Dry drawing is slightly less destructive than wet drawing. The higher the carbon content and the more the wire has been worked in the dies the more liable are cracks which will lead to failure under repeated stress. RHP (6f)

Fatigue Tests in Shear of Three Non-ferrous Metals. H. F. Moore & R. E. Lewis. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 236-242.

The Fatigue Resistance of Spring Steels. G. A. Hankins & M. L. Becker. *Engineering,* Vol. 133, Jan. 29, 1932, pages 141-145.

Condensed from paper entitled "The Effect of Surface Conditions Produced by Heat Treatment on the Fatigue Resistance of Spring Steel" read before the Iron & Steel Institute, Sept. 30, 1931. See *Metals & Alloys,* Vol. 1, Dec. 1931, page 306. LFM (6f)

Properties of Alloys under Dynamic Stresses. G. S. von Heydekampf. *Conference on Metals & Alloys, Case School of Applied Science,* Cleveland, Ohio, Nov. 1931, Paper No. 16, 2 pages. Mimeographed.

The endurance limit of steel is usually about 45% of the tensile strength, but a limit above 110,000 lbs./in.^{2} is seldom met. Steels of tensile strength over 250,000 lbs./in.^{2} generally have lower endurance limits than 110,000. Non-ferrous alloys have endurance limits from 20 to 50% of the tensile strength. These percentages refer to endurance in bending. The endurance limit in torsion is only about half that in bending. The effect of notches on endurance limit is complex, as the same notch has vastly different effects on different alloys. The notch effect has to be found by test. It may be related to "dynamic ductility," i.e., "crackless plasticity" or "damping capacity," but is not directly related to static ductility or to ordinary impact tests. Cold working of the surface improves endurance under bending stress. HWG+Ha (6f)

Alternating Torsional Tests on Zinc Crystals. (Wechseltorsionsversuche an Zink-Kristallen.) W. Fahrenhorst & E. Schmid. *Zeitschrift für Metallkunde,* Vol. 23, Dec. 1931, pages 323-328.

Previous attempts to relate the fatigue limit with other properties of metals are reviewed and their inadequacy indicated. In order to study the question in a simple form single crystals of Zn (1 mm. diam.) were subjected to reversed torsional fatigue in a newly designed machine. After a given number of reversals of stress the shearing and tensile strengths, and elongations, were determined. It is shown that the threshold shearing stress to initiate slip in the basal plane of the Zn lattice, and the tensile strength, during the process of fatigue first increase, then pass through a maximum, and subsequently decrease. The maximum is passed long before the appearance of the first fissure. Thus the crystal at first became stronger, but after a period began to soften. It is suggested that the fatigue strength of a crystal be defined as the maximum stress at which an infinite number of reversals of stress is just insufficient to cause the strength of the material to pass beyond this maximum. RFM (6f)

Fatigue Tests of Low-carbon Steel at Elevated Temperatures. H. F. Moore & N. J. Alleman. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 1, 1931, pages 114-121.

See abstract of preprint. *Metals & Alloys,* Vol. 2, Oct. 1931, page 214. HWG (6f)

Fatigue of Metals. J. A. G. Stewart. *Mechanical World & Engineering Record,* Vol. 89, Feb. 13, 1931, pages 155-158.

The phenomena of the behavior of metals under the effect of stresses caused by loads which frequently fluctuate in value between certain limits, are discussed. The "fatigue of metals" is defined as the behavior of metals when subjected to repeated stresses. Repetition-stresses may be subdivided into: (1) tensile and compressive; (2) reversed bending; (3) alternating torsion; (4) repeated impact; (5) reversed plane bending. The principles of the Wöhler and Haigh tests are set forth and typical S/N curves plotted. These are shown to be similar in type to human endurance curves. The effect of rate of application of repeated stresses has little or no influence on the limits of stress. The only relation with other mechanical properties is that with tensile strength. The theory of fatigue discussed is that originally advanced by Ewing and Rosenhain. WHB (6f)

Slightly Decarburized Surface and Endurance. Correspondence from W. Rosenhain, London, England. *Metal Progress,* Vol. 21, Jan. 1932, pages 67-68.

The writer calls attention to the work of Hankins and Becker on the relation of endurance properties to surface decarburization. WLC (6f)

Modern Problems of Mechanical Vibrations. (Zeitfragen mechanischer Schwingungen.) W. Adrian. *Zeitschrift für angewandte Mathematik und Mechanik,* Vol. 11, Oct. 1931, pages 382-387.

The fourth report of a Committee for Mechanical Vibrations, Munich, 1931, refers to experiments in the Wöhler Institute at Braunschweig, carried out with the object of improving the physical properties of materials by special pressing and rolling treatments of the surface of alloys which are submitted to vibration stresses. The present communication refers to threads which later endured alternating bending stresses. EF (6f)

Corrosion Fatigue Tests on Various Staybolt Materials. H. L. MILLER. *Boiler Maker,* Vol. 31, Aug. 1931, pages 206-208.

Specimens of threaded staybolt material were tested in a cantilever type rotating-beam machine while subjected to a stream of running water at 150° F. This reversed-flexure test was designed to simulate service conditions. All specimens were tested at a stress of 18,000 lb./in.^{2} as computed for the section at the bottom of the thread by the ordinary flexure formula. The relative lengths of life for each material were taken as criteria of service value. Five specimens each for 10 metals were tested. The speed of testing was 1150 r.p.m., or about 1,650,000 cycles of stress per day. The results obtained were as follows:

Material	Corrosion-fatigue Life
Wrought Iron A	8 days 3 hr.
" " B	8 days 15 hr.
" " C	13 days 18 hr.
" " D	13 days 12 hr.
" " E	14 days 18 hr.
" " F	9 days 21 hr.
Toncan Metal	22 days 18 hr.
Nickel	18 days 23 hr.
Toncan Metal Treated	53 days 9 hr.
Nickel Treated	47 days 12 hr.

From tension and impact tests conducted on specimens of the materials the following physical properties, to be obtained by heat treating, are recommended for staybolts in locomotive fireboxes.

Yield Point	45,000-50,000 lb./in.^{2}
Tensile Strength	58,000-63,000 lb./in.^{2}
Elongation in 8-in.	18-23%
Reduction of Area	55-75%
Izod Test	75-100 foot-pounds
Brinell number	116-134

Staybolts showing elongation 10% below the A.S.M.E. or A.R.A. requirements have given satisfactory service in switching locomotives in a hard water district. It is noted by the reviewer that life under a given stress has not proven a very reliable criterion of endurance strength in many studies of fatigue of metals. However, under so low a stress as that used by Miller, life would seem a somewhat safer criterion of endurance service than would life under a higher stress. HFM (6f)

The Influence of the Condition of the Surface Condition on Stress Distribution and the Endurance Limit (Einfluss der Oberflächenbeschaffenheit auf den Spannungs verlauf und die Schwingungsfestigkeit). E. ARMBRUSTER. VDI-Verlag, Berlin, 1931. Paper 6x8¼ inches, 64 pages. Prices 7 RM.

Stress distribution in specimens having different shaped notches was studied on models by polarized light, and results illustrated by figures.

The effect of notches was studied on 3 steels of about 0.30% carbon: one plain annealed steel of 150 Brinell, another heat treated to give 160 Brinell and fine structure, the third a 3% Ni, 1½% Cr, steel heat treated to 270 Brinell; on 3 cast 8½% Cu aluminum alloys; one as cast, 2 heat-treated, and two 15½% Zn, 2% Cu aluminum alloys, one heat-treated and the other as cast.

Rotary beam endurance limits were determined by running specimens at stresses that would break them in 200,000 cycles down to those that would leave them unbroken after 2 million. (*Abstractor:* This is a very small number of cycles for tests on aluminum alloys.) The reciprocal of the number of cycles was plotted against stress instead of using the usual S-N plot. Endurance tests on unnotched bars so made and so plotted were compared with various formulae that have been suggested for approximation of endurance limit from static properties. None of the formulae fitted all the samples. Herold's formula fitted the steels within 5% but was from 70% to 110% off on 3 of the aluminum alloys. Short cut tests are discussed and dismissed as useless.

Various surface finishes: ground, turned and filed, were compared, on the steels, with polished specimens with the usual results. Cold working the surface improved the endurance of the softer steels some 25%, but only 5% on the harder one.

The cast aluminum alloys tested with the casting skin (green sand molds) had 7% to 22% lower endurance than with machined and polished surfaces. No notched tests were made on the aluminum alloy samples.

Similar notches were made in the steel specimens by pressing a cone into them and by a pointed drill also; in another set, by pressing in a notch (at one place, not all round the specimen) with a chisel; by cutting with a tool; and by grinding it in. The cone impression had no effect on endurance; the drill hole cut it 20% to 35%; the chisel notch about 10%; the cut notch 35% to 50% and the ground notch 40% to 55%. Similar notches made all around the specimen (a) by pressing a V edged hard steel disk against the rotating specimen and (b) by turning the notch gave, on the basis of the cross section at the base of the notch, an increase in endurance for 5% to 10% for the pressed notch and a decrease of 25% to 40% with the cut notch. The effect of notches formed so that the base of the notch is cold worked is, therefore, nearly balanced or even overbalanced by the improvement due to cold working. Shallow rounded notches ranged from no effect to a 20% damage. A hole 1 mm. in diameter normal to the axis of the specimen did 25% to 35% damage in rotary bending and 6% to 45% in torsion. The effect of an enlargement of the specimen connected by an 0.3 mm. radius fillet ranged from 2% damage on the softest steel to 30% on the hardest.

The depth and radius of the notch was studied briefly. Since the ground V notch located at one point on the surface produced the most damage, Armbruster suggests as a standard for the determination of notch susceptibility in endurance a 60° V notch 0.2 mm. deep ground in (the endurance specimen not being rotated so that the notch does not go all the way around) with a 60/100 Norton wheel with a sharp 60° angle; the wheel is dressed to the sharp angle before the cutting of each notch. ELECTRO-CHEMISTRY (7)

Electrochemistry and Electrical Engineering. G. W. VINAL. *Electrical Engineering,* Vol. 51, Apr. 1932, pages 238-242.

Fundamental electrochemical processes are discussed in a general way with typical examples for each given case. Included are: electrowinning of Zn (metal deposited from solutions derived from ores or other materials using insoluble anodes), electro-refining of Cu, electroplating and electroforming, electrolysis of fused electrolyes, electrolysis of brine and hydroxide solutions, electric furnaces and electrometallurgy. WHB (7)

Electroplating (7a)

The So-Called Acid Patent Covering Chromium Plating. (Das sogenannte Säurepatent betreffend Verchromung). D.R.P. 448,526. *Deutsche Goldschmiede-Zeitung,* Vol. 34, Aug. 15, 1931, pages 347-349.

Discusses chromium plating methods, the field covered by the above patent and the licensing in Germany for operation under this patent. JLG (7a)

Reads Print Through Five Metal Thicknesses. *Scientific American,* Vol. 146, Apr. 1932, page 251.

Ni has been made in such thin sheets that it is possible to read print through 5 thicknesses of metal placed a few millimeters apart. These Ni sheets were displayed at the Royal Albert Hall, London, during a recent exhibition. The thin sheets were made by electrodepositing Ni upon Cu and then plating Cu on Ni. The Cu was then dissolved away, leaving the Ni. Cu was required on both sides to equalize the stresses caused during the depositing of the Ni which might have ruptured the Ni film. WAT (7a)

Finishing and Galvanizing Aluminum (Die Oberflächenbehandlung und Galvanisierung des Aluminiums)). *Chemiker Zeitung,* Vol. 55, July 29, 1931, pages 579-580.

A review covering acid dips, alkaline cleaning solutions, polishing pastes, steel ball polishing in barrels, lacquering and metal spraying. Plating methods discussed are Ni over Fe, Cr over Zn, Ni direct from solutions containing glycerin, Cu direct and Cd which is claimed to be better than Cu or Ni on Al. CEM (7a)

Nickel Baths and Nickel Anodes. (Nickelbäder und Nickelanoden.) E. WERNER. *Zeitschrift für die gesamte Giessereipraxis, Das Metall,* Vol. 52, Mar. 1, 1931, pages 29-30.

An account of the composition and control of Ni baths is given and the need for high-quality Ni anodes emphasized. WHB (7a)

A Simple Method for Applying a Light Gold Coating. (Einfaches Verfahren zur Herstellung leichter Vergoldungen). THEWS. *Deutsche Goldschmiede-Zeitung,* Vol. 34, Aug. 15, 1931, page 351.

A description of a commonly used method of plating in which no external e.m.f. is required. Directions for preparing the Au solution are given. JLG (7a)

The Importance of the Potassium-Ferri-Cyanide Test. (Die Bedeutung der Ferricyankaliumprüfung.) EUGEN WERNER. *Oberflächentechnik,* Vol. 9, Feb. 16, 1932, pages 31-32.

The test consists in placing a piece of filter paper which has been moistened with potassium-ferri-cyanide on the Ni-plated articles to be tested for denseness of the deposit. After a very short time a blue spot appears on the filter paper where a pore is in the Ni; this is the case for Fe; if the article is of brass or Cu the spot is brown. The author warns, however, against drawing final conclusions on the quality of the plating from these spots; the kind of material on which the deposit is made, the concentration of the bath, and also defects of the ground material can cause spots which have nothing to do with the denseness of the deposit: Also the thickness of the deposit has an influence on the blue coloring of the test. Only if the ground material was very well polished is test reliable. Ha (7a)

Metal Coating. (Metallisation.) J. MICHEL. Desforges, Girardot et Cie., France, 1931. Paper, 4¾x7¼ inches, 200 pages. Price 18 Fr.

Recipes for metal coating are collected in this book, which deals chiefly with electroplating from the point of view of the small jeweler. The author is stated to be an "ingenieur chimiste," but he includes aqueous plating baths for the deposition of aluminum, even though the back cover refers to the "rigorous scientific spirit which governs the choice of the recipes." A worthless volume.

Barrel Rolling and Plating. R. J. O'CONNOR. *Monthly Review American Electroplaters Society,* Vol. 18. Oct. 1931, pages 5-13.

Includes discussion. Paper presented at the Rochester Convention, 1931, of the American Electroplaters Society. Operating details are given of (1) polishing small castings by rolling in horizontal barrel with sand, quartz or pumice and water; (2) ball-rolling with steel balls, soap chips and a little cyanide; (3) dry sawdust rolling to remove oil or grease and to polish screws, etc., using fine, hard sawdust; (4) "wet rolling" in an oblique barrel with sodium carbonate, cyanide and hydroxide, soap, etc., in water for tubular rivets, safety pins, eyelets, etc.; (5) barrel plating with brass, Cd, Cu, Ni and Zn. Whatever hardened parts and springs are to be plated in cyanide bath, the free cyanide content must be kept low to avoid blistering of the deposit. LCP (7a)

The Electrolytic Coating of Metals with Lead Peroxide and Its Anti-Corrosion Properties. (Die elektrolytische Ueberziehung der Metalle mit Bleisuperoxyd und ihre Anti-Korrosions-Eigenschaften.) G. BUCHNER. *Oberflächentechnik,* Vol. 9, Feb. 2, 1932, page 23.

Anodic black-coloring with lead-superoxide for metals is recommended as a simple method for mass articles like radio parts, cutlery, signs, etc. A flexible, well adhering and fine black coating can be obtained in a bath of the following composition: Water 1 l., sodium-hydroxide 40 g., lead 10.5 g., resorcine 0.001%; current density 0.003 amp./cm.^{2}, voltage at an electrode distance of 5 cm., 1 to 1.2 volts, temperature 60°C. Instructions for the preparation of the bath which is still improved by addition of tannin, are given. Ha (7a)

An Efficient Electrotinning Process. F. F. OPLINGER (Roessler and Hasslacher Chemical Company). *Metal Industry*, New York, Vol. 29, Dec. 1931, pages 529-532.

The composition of a tin plating bath is given as follows:

Sodium stannate	12 oz./gal.
Caustic soda	1 oz./gal.
Sodium acetate	2 oz./gal.
Sodium perborate	1/8 oz./gal.
Cathode current density	10-60 amp./ft.^{2}
Temperature	55-75° C.

Its preparation, operation, control and maintenance are described in detail. The cleaning and analytical procedures are included. PRK (7a)

The Electrodeposition of Chromium from Tervalent Chromium Salt Solutions. Part I. Chromium Chloride and Chromium Sulphate Baths. HUBERT THOMAS, STANLEY BRITTON & OLIVER BRENTWOOD WESTCOTT. *Transactions, Faraday Society*, Vol. 27, Dec. 1931, pages 809-826.

A description of experiments conducted with the view of ascertaining the conditions under which it is possible to deposit pure Cr having satisfactory mechanical properties, i.e., fine-grained, smooth, adherent metal. None of the conditions employed in the authors' experiments yielded such deposits. Their purity varied somewhat irregularly over a wide range. Even when the purity was high, the mechanical properties were poor. The behavior of the solutions examined when the hydrogen-ion concentration was varied showed that contamination of the deposits was likely to occur in such unbuffered solutions, since the evolution of hydrogen at the cathode tended to raise the pH to the point at which precipitation of basic matter became possible. Unless crystals of metal can be formed without enclosing basic matter, good desposits cannot be obtained. The authors point out that the effect of increased pH is in fair accord with the view that the higher the pH, the greater the possibility of Cr deposition and the greater the risk of precipitated basic matter on the cathode. These two conditions acting concurrently should cause a change in the character of the deposits which would result in a transient set of conditions under which relatively pure metal could be deposited. The time of electrolysis is an important factor owing to the fact that the quantity of current passed governs the change in hydrogen-ion concentration in the neighborhood of the cathode. The article is accompanied by 5 diagrams and 9 tables. OWE (7a)

The Chromium-Plating Methods for the Most Used Metals and Alloys (Die Verchromungsverfahren für die gebräuchlichsten Metalle und Legierungen). K. ALTMANSBERGER. *Oberflächentechnik*, Vol. 8, Dec. 1, 1931, pages 247-248.

The following tabulation shows the principal methods of chrome plating:

(1) For iron as base metal	(a) alkaline-Cu-Ni-Cr
	(b) brass-Ni-Cr
	(c) Ni-acid Cu-Ni-Cr
	(d) Zn-brass-Ni-Cr
(2) For brass as base metal	(a) Cr
	(b) Ni-Cr
	(c) Cu-Ni-Cr
(3) For cast Al as base metal	(a) Cr
	(b) Ni-Cr
(4) For red brass as base metal	(a) Cr
	(b) Ni-Cr
(5) For die cast Zn as base metal	(a) Cr
	(b) Cu-Ni-Cr
	(c) Zn-Ni-Cr
	(d) Ni-Cu-Ni-Cr
	(e) brass-Ni-Cr

The intermediary layers are selected according to the application. Protection against corrosion requires a minimum thickness of 0.025 mm. The intermediary layers are valuable for the reason that they increase the elasticity of the deposits (in the same manner as the veneer for wood). The method (c) for iron is particularly distinguished by high elasticity. General remarks on the treatment and selection are added. Ha (7a)

Chrome-Plating. (Ueber die Galvanische Verchromung.) E. BECKER. *Die Giesserei*, Vol. 18, Dec. 25, 1931, pages 953-954.

The advantages of Cr-plating are discussed, the principal reason for the rapidly increasing use is the great hardness of the coating; the following table shows the hardness for several metallic deposits:

Metal Coating	Brinell Hardness	Metal Coating	Brinell Hardness
Lead	3-5	Nickel	155-420
Cadmium	12-53	Cobalt	270-311
Zinc	40-50	Chromium	500-900
Copper	58-150		

The practice of applying intermediary plating with Cu or Ni or both and the reasons for it are explained and methods of obtaining good deposits described. With good intermediary plating a thickness of the Cr deposit of 0.0008 mm. is mostly sufficient. The price amounts in general to about 1.5 to 2 times that of a simple Ni plating. Ha (7a)

Plating on Zinc Die Castings. E. A. ANDERSON & E. J. WILHELM (N. J. Zinc Co.). *Metals & Alloys*, Vol. 2, Dec. 1931, pages 337-340.

2 reasons are given for the failure of plating: inadequate thickness and improper method for plating the material in question. The cleaning, rinsing and acid dipping operations of preparing the surface are discussed. The question of a proper primary coating is discussed; the writer presents as best the use of a Ni coating at least 0.0003 in. thick. The disadvantages and inadequacies of a Cu flash are described. Tests are reported showing 0.0003 in. thickness of Ni as necessary to give adequate protection and that greater thickness is without advantage. Testing the quality of electroplated work is discussed. WLC (7a)

Chromium Plating Pure Aluminum and Aluminum Alloys (Das Verchromen von Reinaluminium und Aluminiumlegierungen). K. ALTMANNSBERGER. *Chemiker Zeitung*, Vol. 55, Sept. 16, 1931, pages 709-710.

Due to the affinity of Al for O, direct chrome plating on Al is impossible and Ni is usually used as an intermediate layer. The procedure recommended is to polish the parts and electro-clean in an alkaline solution with reversed current at 7-8 volts for several mins. This roughens the metal and protects it against O. Rinse in clear water and dip in concentrated sodium zincate solution until a silver white Zn coating is obtained. The Zn solution is made by dissolving sheet Zn in 28°-30° Be NaOH. Rinse in water and plate in Ni bath for 1 min. at 2.5 amps./dm.^{2} and 4 volts, then for 30 min. at 1-1.5 amps./dm.^{2} and 2.5-3 volts. A used Ni bath is better than one freshly prepared. It should contain 10 kg. $NiSO_4$, 1.5 kg. acid sodium citrate, 1.5 kg. Na_2SO_4, 1 kg. H_3BO_3 and 250 g. citric acid/100 liters and have a pH of 5.5-6.0. Citric acid produces small crystals, a dense deposit and raises the polarization at the cathode. Then chrome plate at 40° C. for 20 secs. at 5-6 volts and for 3-4 mins. at 4 volts. Pieces plated in this way can be bent at right angles without flaking off the plating. CEM (7a)

Chemical Control of Copper Plating Solutions. L. C. PAN. *Metal Cleaning & Finishing*, Vol. 3, Mar. 1931, pages 217-222; Apr. 1931, pages 309-314.

The procedure of determining and the curves for reading off the Cu content of acid copper plating solutions are explained. Examples illustrate the method. Ha (7a)

Chromium Plating Notes. MEYER ROTER. *Metal Cleaning & Finishing*, Vol. 3, Feb. 1931, pages 151-152.

The influences on good chromium deposits of cleaning methods, lining of the plating tank with glass or lead, the pH of the nickel solution, etc., are briefly discussed. Ha (7a)

Preparing Work for Polished Chromium Plating. W. E. WARNER. *Canadian Machinery*, Vol. 42, Nov. 26, 1931, page 23.

Where Cr plating has to be polished, the preparation of the underlying metal is important. The article should be first polished with No. 46 emery, using a speed of 8,500 ft./min. Successively finer grades of emery should then be employed; no grease should be used with the emery. When buffing, a speed of 14,000 ft./min., at least, should be used; tripoli should be the abrasive and grease used as a lubricant. The piece is then cleaned in an alkali bath, rinsed and plated. If the part is to be plated with Ni or Cu first, it should be buffed before final Cr plating. If this procedure is used, the Cr plating will appear bright and polished on leaving the bath and at the most, only a slight buffing will be necessary. WAT (7a)

The Status of Chromium Plating. WILLIAM BLUM. *Journal Franklin Institute*, Vol. 213, Jan. 1932, pages 17-39; Extended abstract in *Metals & Alloys*, Vol. 2, Dec. 1931, page 365; *Foundry Trade Journal*, Vol. 46, Feb. 25, 1932, page 135.

Presented at Franklin Institute meeting Nov. 5, 1931. A birdseye view of methods and applications, and especially the limitations and probable future uses. Hardness is most striking physical property of Cr. No definite relations exist between hardness and wear-resistance. Cr-plated gages, subsequently heated to 300° C., yielded best service. There is a real need for comprehensive study of factors governing hydrogen content of electroplated Cr, and its effects upon properties of deposits. Color of Cr deposited from H_2CrO_4 is bluish white; reflectivity in visible spectrum is 65%, as compared with 90% for Ag, although Cr reflects much better than Ag in ultraviolet range; has high electrical conductivity but is not suitable for contacts due to presence of oxide film; Cr surfaces not easily wetted and hence soldering is difficult. Resistance to tarnish is most important chemical property, but Cr will not prevent corrosion of underlying metals such as steel. Good commercial Cr plating is done with insoluble Pb or Fe anodes, in H_2CrO_4 solution, containing small amount of sulphate, 250 to 400g. CrO_3/liter, and CrO_3/SO_4 ratio 100 to 200, temp. 45° C., current density 100 to 150 amps./ft.^{2} Poor throwing power has been overcome by (1) increasing distance between anodes and cathodes; (2) using parallel concentric or auxiliary anodes; (3) attaching to cathode a wire which acts as a "thief"; (4) using non-conducting shields to reduce excessive current density. Cleanliness and good ventilation are necessary in plating shop to avoid injurious effects upon workmen.

Calculations of Ampere-Minutes in Plating. CHARLES H. ELDRIDGE. *Metal Industry*, N. Y., Vol. 30, Mar. 1932, pages 111-112.

A set of 4 tables for alkaline Cu and Cd plating, and Ni and acid Cu plating is given, showing the relationship between thickness of deposit, ampere-minutes/ft.^{2} and current efficiency. An example of how to use them is given. PRK (7a)

Procedures to Preserve Alloys and Steels Against Corrosion by Atmospheric Agents. (Procedes de preservation des Alliages et des aciers contre les degradations causes par les agents atmospheriques.) *Bulletin de la societe chimique de Belgique et Recueil des travaux chimiques Belges*, Vol. 40, Feb. 1931, pages 129-143.

A lecture dealing mostly with Co and Cr electroplating. WHB (7a)

Electroplating Aluminum with Copper. (Die galvanische Verkupferung des Aluminiums.) R. WEINER. *Zeitschrift für Elektrochemie*, Vol. 37, July 1931, pages 349-356.

A process for electroplating Al with Cu proposed by H. Ginsberg is described and the conditions for testing a satisfactory deposit are laid down, micro-examination being especially useful. The oxide film on the Al is first removed, and the surface is roughened by anodic oxidation and chemical treatment; the Al is then plated in a cyanide bath, a good deposit being so obtained. Experiments showed that the conditions for successful plating lie within fairly narrow limits, and that exceeding those limits leads to a worthless deposit. Plating in a copper chloride HCl bath of varying proportions and concentrations has not yet been successful. The composition of the Cu plating bath is the following: $K_3Cu\ (CN)_4$, 40g., KCN, 1g., Na_2CO_3, 10g., Na_2SO_4, 20g., $NaHSO_3$, 20g., water, 1 liter. Ha (7a)

Competition, Technically and Commercially, between Electrolysis and other Methods of Metal Extraction and Refining. (Die Elektrolyse im technischen und wirtschaftlichen Wettbewerb mit anderen Verfahren der Metallgewinnung und Raffination.) H. WOHLWILL. *Metall und Erz*, Vol. 29, Jan. 1932, pages 1-9; *Chemical Age, London*, Vol. 26, Mar. 5, 1932, Metallurgical Section, page 14.

Contains 7 references. In 1930 electrolytic processes represent 8.5% of the world's Cu produced, 90% of world's Cu refined, 13.5% of the Pb produced, 28.3% of the Zn refined and 55.7% of the Cd refined. Local conditions influence the economy of refining methods. 99.9% pure Cu has become a necessity in the electrical industry and 99.99% Zn, electrolytically refined, is now available and commands a higher price. Ni and As have been the largest impurities in electrolytic Cu. As can be removed by treating the acid electrolyte with SO_2 under pressure. As_2O_3 precipitates and can be recovered 99% pure. Purer metals can be obtained by electrolysis, but the impurities in the form of intermediate products, sediments and solutions present greater problems. Pb is not produced so much electrolytically, but for complete removal of Bi it is the only available process. Bi is recovered by electrolysis in HCl solution, but contains some Ag. For Pb free from Cu, containing 1 to 2% impurities of As, Sn and Sb the Harris process is best. Electrolytic Sn production is not yet important. Although smelting of Ni is very complicated it is more economical than electrolysis. For very pure Ni electrolysis is required after smelting. CEM (7b)

Electrolytic Zinc Plant of the Sullivan Mining Co. W. G. WOOLF & R. M. MILLER (Sullivan Zinc Plant). *Mining Congress Journal*, Vol. 17, Nov. 1931, pages 624-627, 640.

First industrial plant using Tainton high acid, high current density electrolytic zinc processes, located at Silver King, Idaho. Present nominal capacity is 60 to 75 tons of cathode zinc every 24 hrs. Five 270-ton capacity reinforced concrete bins raise the concentrates from cars; at the normal rate of feed this is a 10-day supply for the roasters. Five 25-ft., 8-hearth Wedge roasters, each yielding 40 tons per 24 hrs., with special air-cooled rabble arms. A 14-inch Jacoby conveyor takes the calcines from the roasters to a 20-mesh Leahy vibrating screen, the undersize passing to 2 Dings-Wetherill magnetic separators by means of screw conveyors. Leaching is done in three 20′ × 13′ Woodstove, lead-lined agitator tanks, heating done by lead steam coils. 6 Bust filters take the leached pulp from a surge tank. The filters are the rotary internal pressure type, each 4′6″ i. d. × 40′ long. Electrolyte circulates continuously from the cells to a 42′ Pb lined balance tank, pumped by Antisell Pb lined pumps to 5 cooling cells. Inlet to cells is by hard rubber pipes and outlet through a hard rubber overflow pipe to sumps below. Each cell contains 20 Pb alloy anodes and 10 sheet Al cathodes, the anode being cast in a grid shape to permit better circulation with higher current efficiency. The electrolytic system is cells in each unit in series and cathodes in each cell in parallel. Cathode melting furnace is a small reverberatory, 15′ wide × 28′ long, charged through a swinging door at the top. At the flue end of the furnace built into the hearth are 2 wells from which Zn is ladled into 2 steel plate ladles suspended from a trolley. Mold racks are below the trolley beams, casting is by hand, each slab 60 lbs. The product averages 99.99+% pure, with .001% to .002% Cd, Pb, Fe, Cu. This pure Zn has 30% greater ductility than that of other high grade brands, also higher corrosion resistance, elimination of hot shortness to a large extent in the die-casting trade, thus decreasing cracking upon removal from molds, and greater tensile strength. The electrolytic Cd plant and dust recovery Cottrell plant are also explained. DTR (7b)

Contribution to the Fundamentals of Technical Zinc Electrolysis. (Beitrag zur Kenntnis der Grundlagen für die technische Zinkelektrolyse.) P. RÖNTGEN & R. BUCHKREMER. *Metallwirtschaft*, Vol. 10, Dec. 11, 1931, pages 931-936.

Contains 16 references. Hydrogen overvoltage and cathode potential measurements in pure Zn solutions with polished electrodes were made with current densities between 1 and 40 amps./dm.². In this region the deposit potential $E = a + b \times \log \frac{i}{q}$, where i = current density and q = cathode area. The constants a and b depend on the operating conditions. The tests covered the effect of time of measurement on cathode potential and hydrogen overvoltage, the surface condition of the cathode, temperature and acid concentration on hydrogen overvoltage, Zn content of the electrolyte, temperature, and acid concentration on the cathode potential of electrolytes containing Zn. The results of these tests are given in graphical form. The yield of Zn remains constant with an increase in current density in solutions of low Zn content, but increases in solutions with high Zn content, provided the diffusion rate in the solution is high enough. Increase in temperature and stirring are beneficial as they increase the diffusion rate. With increasing acid concentration the yield decreases, temperature being constant, the more so the lower the Zn content is. In weakly acid solutions a rise in temperature decreases the yield, but in strongly acid solutions it increases it. If the acid concentration and current density are raised at the same time, an increase in temperature has a beneficial effect on the yield. The effect of a change of one factor depends on the other factors. Potential measurements were also made with low current densities, below 1 amp./dm.². In this region the potential does not follow the equation. At about 0.5 amp./dm.² it falls vertically to the value of the Zn potential. With $ZnSO_4$ additions the drop is less pronounced. CEM (7b)

Development of Electrolytic Metal Production. (Entwicklung der elektrolytischen Metallgewinnung.) *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Feb. 7, 1932, pages 74-75.

The paper describes German plants for electrolytic metal production with special reference to those of the Norddeutsche Affinerie, Hamburg. GN (7b)

Phosphor Bronze—Its Electrical Properties and Applications. WILLIAM CRAWFORD HIRSCH. *Electrical Manufacturing*, Vol. 8, Dec. 1931, pages 30-32.

In phosphor bronze, the phosphorus is a purifier mainly. It is present in very small quantities, and serves to rid the bronze of oxides. In electrical manufacture, this metal is used for bearings, and in switches for parts where strength and toughness must be accompanied by elasticity and resistance to corrosion. It is highly resistant to break-down under arcing conditions. Its tensile strength is as high as 130,000 lbs./in.². Many of its available forms and applications are enumerated. WAT (9)

Brass, Bronze and Copper Alloys. W. R. HUBBARD. *Conference on Metals & Alloys, Case School of Applied Science*, Cleveland, Ohio, Paper No. 4, Nov. 1931, Mimeographed, 7 pages.

General statement as to compositions of wrought alloys commercially available and some of their uses. Architectural uses are specially considered. No copper base alloy is resistant to tarnish in the atmosphere. The use of Everdur (96% Cu, 3% Si, 1% Mn) nails on shingles and clapboards is suggested to avoid rusting and loosening. It is also advocated for hot water storage tanks. HWG (9)

Light Metal-Alloy Pistons and Rods. BENEDICT J. ISIDIN (Aluminum Co. of America). *Motive Power*, Vol. 2, Sept. 1931, page 22.

The speed of oil and gasoline internal-combustion engines has been brought into a higher range following the availability of improved materials and the necessity of obtaining increased output without sacrificing space and weight. This often makes it necessary to reconsider some points of design and to adopt better grades of material to solve the problems of higher heat stresses and increase in dynamic bearing loads. As a satisfactory means of reducing the weight, the author discusses the use of Al, allowing heavier sections, preserving the rigidity and removing any thermal difficulties encountered in the piston. WHB (9)

Savings in Running Expenses by Weight Reduction of Vehicles. Utilization of Aluminum Alloys for the Construction of Busses and Street Cars. (Betriebsersparnisse durch Gewichtsreduzierung bei Fahrzeugen. Zur Frage der Verwendung von Aluminiumlegierungen beim Bau von Autobussen und Strassenbahnwagen). A. M. HUG. *Zeitschrift des Oesterreichischen Ingenieur- und Architekten Vereins*, Vol. 83, Sept. 1931, pages 285-289.

The economical utilization of aluminum-alloys for various parts of transport system constructions are discussed and illustrated. See also *Metals & Alloys*, Vol. 2, July 1931, page 131; Nov. 1931, page 260. EF (9)

Light Alloys in Aircraft. H. W. GILLETT. *Conference on Metals & Alloys, Case School of Applied Science*, Cleveland, Ohio, Nov. 1931, Paper 19, 6 pages. Mimeographed. *Heat Treating & Forging*, Vol. 18, Feb. 1932, pages 98-101.

The paper deals with the principles of the engineering choice of materials for aircraft construction. Some of the properties of light alloys cannot be chosen arbitrarily; for instance, specific gravity, modulus of elasticity. On the other hand, properties like yield strength, in general physical properties of behavior in service, can be influenced at will by proper alloying and heat treatment. The designing engineer must select, from the choice the metallurgist puts at his disposal, that alloy combining in the happiest way the properties desired for his special purpose. The points of view entering and determining the choice for the various parts in an aircraft are briefly discussed. 4 main groups are singled out which are then dealt with in greater detail; namely, light alloys, comprising heat-treated Al of the duralumin type, Mg alloys, strong alloys comprising heat-treated alloy steels and cold-worked corrosion-resisting steels. See "Some Characteristics of Light Alloys for Aircraft," *Metals & Alloys*, Vol. 2, Jan. 1931, page 8. MS + HWG + Ha (9)

The Selection of Materials in Machine Design. W. TRINKS (Carnegie Inst. of Technology). *Rolling Mill Journal*, Vol. 5, Apr. 1931, pages 285-289.

An abstract of a paper presented before the Steel Founders' Society at Columbus, Ohio, Mar. 1931. Gives a comprehensive list of the construction materials used in machine design and discusses the principles of selection, properties, special applications, and particular uses of each. JN (9)

Wear of Trolley Bus Wires. *World Power*, Vol. 27, Feb. 1932, page 89.

There are 2 primary causes for the wear of trolley bus wires: mechanical friction and arcing between the collector and the wire. A communication from the Institute of Electrical Engineers of Japan based mainly on operating experiences emphasizes the importance of choosing material with a high melting point as well as with the necessary degree of hardness to resist mechanical friction. Cd Cu wire appears to give a life twice as long as hard-drawn Cu wire. Si Cu wire appears to possess the same degree of advantage. It is reported that the wear of the steel contact conductor of the armoured trolley wire was negligibly small and of the order of 310 square mils for 48,600 times passing the collector. WAT (9)

Chrome Vanadium Steel Pressure Vessels. *Vancoram Review*, Vol. 3, Jan. 1932, pages 7-12.

A number of analyses of steel for forging and heavy plates are given; they contain 1.0 to 1.25% Cr, 0.15 to 0.2 V and show a tensile strength from 70,000 to 105,000 lbs./in.^{2} and an elongation between 20 and 25%. A few containers of various shapes are illustrated. Ha (9)

Uses for the Rare Metals. *Scientific American*, Vol. 146, Apr. 1932, pages 248-249.

Metallic Ba (99.95%) has recently been produced as a commercial article, and is supplied to manufacturers in the motor car industry, where it is used in a high-Ni alloy. In the radio industry, the metal is used to clean up the last traces of gas in vacuum tubes. It is expected that the consumption will be increased to a substantial amount in the near future. Pure Mo is now used in the electrical and radio industries in many forms. Ce, when alloyed with Fe, Zn, or other base metals, produces pyrophoric alloys, which are used in pocket-lighters. Ce and ferro-cerium are also powerful reducing agents. Cs and Rb are used in the manufacture of photo-electric cells. Cs is also used in eliminating the last trace of gas from vacuum tubes. Recently, metallic Li has found use as a deoxidizing agent in refining Cu; it does not appreciably reduce the electrical conductivity of Cu. Metallic Ta is now available. Because of its resistance to corrosive action it has already found extensive use as a cheaper substitute for Pt and Pt-Au alloys in spinnerets for rayon manufacture. Tantalum carbide is proving to be an excellent cutting-tool material. Cb is now replacing Pt in the jewelry industry. It takes a very fine finish and may be colored in many hues by an electrolytic method. It is inert to most chemical reagents. WAT (9)

All-Metal Building for Richmond Public Works Department. *Engineering News-Record*, Vol. 108, Mar. 24, 1932, pages 441-442.

First structure of its type for office use in this country. It is a 2 story structure, with a frontage of 116′ and a depth of 50′. Structural steel frame is utilized with open-web joist floors and roof covered by pressed steel deck plates. The inner and outer walls make extensive use of Al. Construction details are included. CBJ (9)

Rail Durability. *Engineer*, Vol. 152, Dec. 18, 1931, page 659.

Abstract of article from the *South African Engineer*. In relaying one line of the South African Railway some 45-lb. rails dating back as far as 1868-1875 were removed and found to be in excellent condition. Steel sleepers dated 1895-1896 were found to have withstood the increasing weight and speed of the trains remarkably well. They were still free from rust. LFM (9)

Reduction of Weight of 300 Suburban Cars by the use of Light-Metals. (Allegement de 300 Voitures de banlieue par l'Emploie des Alliages legers.) *Revue d'Aluminium*, Vol. 8, Mar.-Apr. 1931, pages 1364-1370.

The construction of the cars with Duralumin, Alpex, and cast aluminum alloys is described. Ha (9)

Aluminum Placed on Trial in Hopper Cars. *Railway Age*, Vol. 92, Mar. 26, 1932, pages 516-518.

When the Alcoa Ore Company, subsidiary of Aluminum Company of America, recently placed in service ten 70-ton hopper cars with bodies made of Al, it definitely put the metal on trial as a material for freight car construction. The cars are of standard construction and design and contain approximately 12,500 lbs. of Al plates, shapes and castings. A saving of 21,200 lbs. of dead weight are accomplished over the usual steel type of construction. The materials which are incorporated in this new hopper car are the Aluminum Company's 17SO, 17ST, 4S¼H and 4S½H in the wrought condition, and 43 and 197-57 in the cast condition. WAT (9)

Electric Line Installs High-Speed Aluminum Cars. *Railway Age*, Vol. 91, Sept. 12, 1931, pages 403-404.

Practically complete Al structure is the principal factor in a weight reduction of 40,000 lbs./car. 35 cars of this type have recently been purchased by the Indiana Railroad System, which operates 5,000 mls. of track, largely in Indiana. The bodies and under frames are all Al; the cars are capable of a speed of 70 mi./hr. The cars are 46 ft. in length between bumpers. WAT (9)

Metal and Manufacture of Pipe Lines. *Petroleum World*, London, Vol. 28, July 1931, pages 215-223.

A detailed discussion of pipe line metals and their various advantages for use in oil lines. (9)

Large Uses of Steel in Small Ways. Vol. II. Penton Publishing Company, Cleveland, 1931. Cloth, 9 x 11½ inches, 80 pages. Price $2.50.

In 1923, Iron Trade Review, the predecessor of Steel, began the series of notes on the uses of steel in small parts, some 50 such uses being collected in Vol I, while Vol. II contains nearly 100.

These range from artificial limbs, through bottle caps, card tables, cork screws, hair clippers, lock washers, maple sap spouts, suspender buckles, tire chains, typewriter spools, wire lamp shades, etc., etc. The way the steel is used, the tonnage required, and an illustrative photograph are usually given.

These accounts are interestingly written, and should be of interest to manufacturers looking for new uses for metals. The tonnages required in some of the "minor uses" are quite remarkable. H. W. Gillett (9)-B-

Protection of Concrete by Metallic Coatings. (Schutz von Beton durch Metallüberzüge.) R. Grün. *Zement*, Vol. 20, Sept. 17, 1931, pages 855-858.

Tests during a period of 1½ years with concrete samples covered by a coating of (a) bitumen, (b) sprayed Zn, (c) triple Pb spray and (d) a five-fold Pb spray and submerged in H_2O, 5% HCl, 5% $(NH_4)_2SO_4$ and 10% $MgSO_4$ solutions. The mechanism of destruction in the case of bituminous coatings is said to be characterized by the formation of blisters caused by the diffusion of the liquid thru the semi-permeable coating (membrane) due to the osmotic pressure. This phenomenon does not occur with metallic coatings which exhibited a decided superiority which might even be furthermore improved if the surface of the concrete were given a smooth finish. Includes 14 illustrations. EF (9)

Wrought Iron Tubes. G. M. Gill. *Gas World*, Vol. 96, Jan. 16, 1932, page 49.

Letter to editor commenting on letter from Reginald Terrell in issue of the Gas World of November 21st. Gill discusses the advantages of distinguishing Armco iron and wrought iron in ordering material for manufacturing gas service pipes. MAB (9)

American Skyscrapers. (Le Gratte-Ciel Américain). Icre. *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Aug. 1931, pages 368-382.

A lecture before the "Societe des Ingenieurs Civils de France." Deals generally with the requirements for structural steels used in large buildings. GTM (9)

Federal Reserve Bank of Pittsburgh Utilizes Cast Architectural Decorations. Norman F. Hindle. *Foundry*, Vol. 59, Oct. 15, 1931, pages 26-29.

Many of the decorative features were cast in Al and Monel metal by the Harsch Bronze & Foundry Co., Cleveland. The metal used for the castings conforms to the following specifications: Ni, 67%; Cu, 28%; Fe, under 3.5%; Si, 0.75-2.0%; C, 0.15-0.25%; Mn, under 0.50%; S, as low as possible. The mixture used consisted of Michigan lake and No. 2 Albany and a cereal binder in the ratio of 35 parts sand to one of binder. Added dry metal is melted in No. 70 carbide crucibles in gas fired pit furnaces. Cores for Monel metal castings were made of the same sand mixture as the molds. VSP (9)

Investigation of American Condensing Systems. (Erfahrungen an amerikanischen Kondensationsanlagen.) K. Hoefer. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 13, Feb. 1932, pages 51-52.

Discusses the various alloys used for protecting pipes and pipe connections, e. g., an alloy of 70% Cu, 29% Zn, 1% Sn; Muntz metal; Al bronze (92.3% Cu, 7.7% Al); an alloy of 85% Cu, 14% Zn, 1% Sn; an alloy of 62.7% Cu, 37.3% Zn. Also considers the construction of old condensers as compared with the new ones of high capacity, the arrangement of the condensers, the chlorination of the cooling water, and the construction of the air pumps. MAB (9)

Cast Crankshafts Replace Forgings. H. M. Heyn. *Foundry*, Vol. 59, July 1, 1931, pages 57-58.

Crankshafts, connecting rods, etc., have been made by hot forging for many years. Steel castings made of an alloy steel of special analysis are now used for that purpose. Triple heat treatment imparts better properties. A Ni-Mn steel is used by the Industrial Steel Casting Co., pioneers in this field. 3 furnaces are used to heat treat castings; each uses a different fuel. Burners are manifolded to Venturi type inspirators. The waste products are vented through a series of flues built in the walls of the furnace. VSP (9)

Making the Steel Saddles for the Hudson Bridge Cables. II. Machining the Saddle Castings for Hudson River Bridge Cables. Sidney G. Koon. *Iron Age*, Vol. 128, Nov. 5, 1931, pages 1174-1177; Nov. 12, 1931, pages 1230-1233, 1281; *Foundry Trade Journal*, Vol. 45, Nov. 26, 1931, pages 329-330.

8 cast steel saddles, each weighing about 18 net tons, are used. They were made and machined by the Midvale Co., Nicetown, Philadelphia. Each casting was made from one ladle of metal from an open hearth furnace. The weight of the metal was about 165,000 lbs. in the largest molds, and 100,000 lbs. in the smallest. Pouring was from full open nozzle until metal was half way up the risers. To keep the cope from "floating," riser boxes were bolted to the flask. Each casting was left in the sand for about 5 or 6 days before the risers were burned off. Final annealing for 5 days at 1650° F. was followed by complete descaling. Chemically, the castings are of plain C steel, having about 0.25% C and 0.50-0.60% Mn. Machining of castings is important not only because of great size, but because of close tolerances demanded. Some novel methods which have been adopted in machining by making use of the existing equipment in so far as it was practicable are described. OWE + VSP (9)

Developments in Steel Construction. *Mining Journal*, Annual Review No., Feb. 13, 1932, page 16.

Uses of steel in mines are discussed. AHE (9)

Commercial Vehicle Bodywork in Aluminium. *Metal Industry*, London, Vol. 39, Aug. 1931, pages 180-182.

The progress is reviewed which was made lately in the use of light metals in freight cars, passenger coaches, busses, etc. Standardization of parts is advocated to accelerate delivery. Ha (9)

Steel Castings in Machine Tool Construction. *Machinery*, Vol. 38, Dec. 1931, page 247.

Due to the use of tungsten carbide and special steels greater strength is needed in machine frames, tool holders, etc. This may be secured by use of cast steel in place of iron. The physical properties of a low alloy cast steel used extensively today are: tensile strength 144,000 lbs./in.^{2}, yield point 126,000 lbs./in.^{2}, elongation 14.5%, reduction of area 37.5%, Brinell hardness 300, impact strength (Izod) 13 foot-lbs. Time and Temperature in Metal Working. *Iron and Steel of Canada*, Vol. 15, Jan. 1932, pages 6-7.

An article, accompanied by 3 figures, in which a discussion of the use of Elinvar in the production of hair springs and monometallic, non-magnetic balance wheels occurs. OWE (9)

HEAT TREATMENT (10)

Thermal Treatment of Steels. W. R. Berry. *Electrician,* Vol. 108, Jan. 8, 1932, pages 34-37; Feb. 12, 1932, pages 215-218.

The underlying principles of heat treatment and the effect on design are discussed. Tempering, normalizing and engineering steels and thermal treatment and case hardening and other surface processes are discussed and the need of the use of the right steels pointed out. WHB (10)

Heat-Treating Modern Twist Drills. J. B. Nealey. *Steel,* Vol. 89, Dec. 28, 1931, pages 23-25.

Kind of steels used and the installation for heat treating are described. Ha (10)

Duralumin Requires Special Treatment. Maximum Resistance to Corrosion Obtained by Cold Water Quench. B. K. Price. *Steel,* Vol. 88, Feb. 12, 1931, pages 31-33.

A description of the aircraft factory of the Glenn L. Martin Co., Baltimore, Md. The heat treating of duralumin is performed in a nitrate furnace, fired with gas, at a temperature of 925° F. All duralumin is quenched in cold water to secure maximum resistance to corrosion. JN (10)

Maintenance of Pulverizer Parts. M. C. Carver. *Power,* Vol. 74, Dec. 22, 1931, page 893.

Heat treatment of coal pulverizer hammers increased life from 3 to 15 months. Surfacing or plating had no effect. AHE (10)

Heat Treatment and Cooling Method for Cast Tin Bronzes. (Zur Kenntnis der Wärmebehandlung und der Abkühlungsweise von gegossenen Zinnbronzen.) Hiroshi Imai & Masami Hagiya. *Memoirs Ryojun College of Engineering,* Vol. 4, May 1931, pages 99-110.

The effects of annealing upon the grain size of cast alloys and of cooling velocity upon the repression of the eutectoid in the β-solid solution were investigated by means of a differential dilatometer. Annealing above 500° C. produced abnormal expansion in alloys up to 15% Sn. Inner strains were easily removed by heating to 600° C. A 26% alloy was cooled in water at the rate of 5000° per min., in oil at 3000° per min., in air at 200° per min., and in a furnace at 10° per min. Cooling at 5000° per min. decreased the Brinell hardness, at 200° per min. increased it. The tension set up by rapid cooling produced cracks in the test specimens. WHB + Ha (10)

Heat Treating Costs Assume New Role of Importance. J. H. G. Williams (Henry Souther Eng'r'g Co.). *Steel,* Vol. 88, Jan. 15, 1931, pages 38-39.

During the past year the overhead cost of automatic heat treating equipment has been subjected to a closer scrutiny in the light of decreased production and the actual merits of special steels have been considered from a more rational viewpoint based on long-time service tests. Progress in the heat treating industry is shown by the rapid increase in the use of gas fuels, the development of several new types of continuous and semicontinuous furnaces for special purposes, wider interest in the control of furnace atmosphere, such as the use of hydrogen gas in normalizing and annealing processes, and the continued development and expansion of the nitriding process. The author cites the need of better methods and tests for determining the uniformity of heat treated tool steels. JN (10)

Hardening (10a)

Continuous Liquid Heat Treating Process. W. Gordon Park (Kelsey-Hayes Wheel Co.) *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1065-1066; *American Gas Journal,* Vol. 136, Jan. 1932, pages 35-36.

Kelsey-Hayes Wheel Co. has installed continuous liquid heating equipment for the hardening of rear-wheel truck hubs. This displaces hardening by the batch method, using hand labor. Furnace was designed for a capacity of 90 hubs/hr. at a batch temperature of 1600°-1670° F. Combustion chamber temperature below the pot is about 1950° F. Pb hardening pot is 21" wide, 15" deep and 7.5 ft. long, supported on cast iron top plates by means of flanges cast integral with the alloy pot. Furnace is fired with diffusion and tunnel type burners, adapted to a supply of 530 B.t.u. gas. Hubs are placed in a specially designed carrier which is removably suspended from the furnace conveyor. They are taken through a preheater and are then lifted automatically over the Pb pot and immersed to a specific point for 197 secs. The hub is lifted out of the furnace and placed on a stationary support which suspends the hub ¾" on the lower end in the oil bath; the cycle is 1-5.5 secs. The inside of the hub is then sprayed for 29 secs. with NaOH; the spraying is automatically controlled. The hub is then completely immersed in an H_2O bath for about 5 mins. The lifting is done by means of a transfer mechanism. CBJ + MS (10a)

Flame Hardening of Rubbing Surfaces. Correspondence from G. Prachtl, Brandenburg, Germany. *Metal Progress,* Vol. 21, Jan. 1932, pages 72-73.

Describes a new process for surface hardening of shafts and gears. WLC (10a)

Annealing (10b)

Strip and Sheet Annealing in the Electric Furnace with Atmosphere Control. Wirt S. Scott. (Westinghouse Electric & Mfg. Co.) *Iron Age,* Vol. 128, Dec. 3, 1931, pages 1422-1425.

Great economies are accomplished in bright annealing of Fe and steel strips and sheets in electric furnace with artificial atmosphere control. By means of correct design uniform heat treatment is accomplished. Discolored surface may be due to air, oil and grease, or to excess of hydrocarbons in atmosphere. The longer the charge is in process of heating and cooling the greater the opportunity for oxidation. The problem of maintaining the same analysis of steel is of importance. The material may be affected by the kind of gas used for atmosphere control. The Westinghouse Elect. & Mfg. Co. has developed a bright annealing process, consisting of gas-atmosphere generating equipment, and an appropriate electric furnace. VSP (10b)

On the Variations of Dimensions Produced by the Annealing of Hardened Copper. (Sur la variation de dimensions produite par le recuit dans le cuivre écroui). A. Schweitzer. *Comptes Rendus,* Vol. 194, Feb. 1, 1932, pages 449-450.

In the course of a study on the manufacture of recoil cylinders for guns, it has been ascertained that Cu previously hardened shows variations in dimensions when it is subjected to annealing. The author has attempted to determine the relationship between the magnitude of these variations and the conditions of working and of annealing. The cylinders used as test pieces (cylinders 8 mm. in diameter and 30 mm. high $\pm$ 1/100 mm.) were manufactured by cutting bars 8 mm. in diameter, obtained by drawing. The bars were all produced from the same casting and did not differ from one another in hardness. The copper contained 99.963% Cu. Variations in the amount of deformation were obtained by varying the diameter of the annealed bar prior to final drawing. After manufacture the cylinders were submitted to an anneal at temperatures between 300 and 800° C. (time, 50 min.). This treatment served to ensure that an annealed condition corresponding with each temperature had been obtained. The annealing was in all cases carried out in nitrogen. Measurements of height were made on at least 10 similarly treated samples. It has been found that for Cu which has undergone a specific treatment and has then been annealed the variation in height is negative, nil, or positive, as the temperature is lower, equal to, or higher than a certain limiting value. This temperature, which is in the neighborhood of 600-650° C., increases as the amount of work decreases. Other things being equal, the change in height which occurs on annealing appears to be independent of the amount of work put upon the Cu when the temperature is below about 550° C. For temperatures above 650° C. the change in height is always positive. OWE (10b)

Use of Dissociated Ammonia as Atmosphere in Annealing Strips and Sheets. Wirt S. Scott (Westinghouse Elec. & Mfg. Co.) *Iron Age,* Vol. 128, Dec. 17, 1931, pages 1548-1551.

Discussion of the action of gases on metals in connection with electric furnaces and controlled atmosphere for annealing. The manner in which anhydrous ammonia, dissociated, may be used to advantage in producing atmosphere in which annealing can be carried out without danger of damage to the surface of the steel is shown. The hard drawn Cu wires are annealed at 550°-650° C. in pots filled with charcoal for about 5 hours. The process and precautions, particularly the insurance of a most perfect seal so as to exclude the air, are considered. EF (10b)

Case Hardening & Nitrogen Hardening (10c)

Case Carburizing of Iron and Steel in Mixtures of Sodium Cyanide. (Die Einsatzhärtung von Flusseisen und Stahl in Cyannatrium- Mischungen.) M. Stromeyer. *Die Werkzeugmaschine,* Vol. 36, Jan. 30, 1932, page 25.

The article briefly discusses case carburizing with special reference to the salt mixtures used in cyaniding. According to the author the following salt mixture is best fit: 30% sodium cyanide, 35% sodium carbonate and 35% sodium chloride. This mixture has a melting point of around 635° C., is an excellent carburizer and is distinguished by a high stability of the sodium cyanide. The procedure to be used is outlined. GN (10c)

Surface Steel Plating and Hardening of Iron Ware. (Die Oberflächenverstahlung und-Härtung von Eisenwaren.) H. R. Reininger. *Metallwarenindustrie und Galvanotechnik,* Vol. 29, Mar. 1931, pages 261-266.

The principles of surface hardening and steeling are discussed and the treatment described in detail. Ha (10c)

Cause of the Abnormal Behavior of Steels during Case Hardening (Ursache des abnormalen Verhaltens von Stählen bei der Einsatzhärtung). F. Duftschmid & Ed. Houdremont. *Stahl und Eisen,* Vol. 51, Dec. 31, 1931, pages 1613-1616.

Whereas M. A. Grossmann (*Metal Progress,* Vol. 18, 1930, page 33) attributes the abnormality of steel to the oxygen content, the authors found this peculiar type of structure to be due to the following causes. In case hardening, electrolytic iron and powdered iron made of iron carbonyl, for 6 hrs. at 950° C., the specimens showed an entirely abnormal structure. Furthermore, steels made by mixing powder of iron carbonyl with purest soot of carbon-hydrogen gas and sintering these mixtures for 3 hrs. at 1050° C. showed an abnormal structure either after forging or after forging and subsequent normalizing. Hardening tests of these steels developed soft spots when hardened in water but were uniform when quenched in brine. Since the oxygen content of the steels varied between 0.0008% and 0.001%, oxygen cannot be the cause of the abnormal structure. It is shown that abnormal structure is brought about when the Ar'-transformation is high and the velocity of diffusion of cementite and its velocity of crystallization below Ar' is large. A high velocity of crystallization is obtained when the Ar' transformation is not greatly retarded, i. e., when there is only a slight hysteresis between Ac' and Ar'. For the very reason of the lowering of the A' transformation, no abnormal structure was observed in the above mentioned pure carbon steels when alloyed with Mn, Cr or other elements. 5 references. GN (10c)

Waste Gases Developed during Hardening and their Dangers (Beim Härten entwickelte Abgase und ihre Gefahren). FREITAG. *Oberflächentechnik*, Vol. 8, Dec. 1931, page 248.
Many of the so-called hardening powders have ingredients which develop noxious gases or even explosive mixtures in the hardening (nitriding) vessel. They should be directed so that, after opening, the operating force cannot inhale them except in very diluted concentrations which are not dangerous. Ha (10c)

Sliding Gears Hard Broached to Close Limits. E. F. DAVIS. *Steel*, Vol. 88, Apr. 9, 1931, pages 41-44.
A plug inserted while carburizing prevents shrinkage of holes. Ha (10c)

Nitriding Steels. H. A. DEFRIES. *Conference on Metals & Alloys, Case School of Applied Science*, Cleveland, Ohio, Nov. 1931, Paper No. 7, 6 pages. Mimeographed.
A correlated abstract briefly covering some of the ground more fully covered by Grossmann and Harder (*Metals & Alloys*, Vol. 2, Sept. 1931, pages 132, 150). DeFries states that the average nitriding cycle is now 36 to 48 hrs., and that the days of the batch furnace are numbered; continuous furnaces will soon be available in which nitriding can be done at a cost equal to that of case carburizing. HWG+Ha (10c)

Continuous Carburizing by Gas. R. J. COWAN. (Surface Combustion Corp.) *Metal Progress*, Vol. 21, Feb. 1932, pages 44-48.
The author describes the practical details of a continuous gas carburizing process recently developed in the laboratories of the Surface Combustion Corp. The process employs one of the lower hydrocarbons diluted with fuel gas. The mechanical features of the furnace are illustrated in a drawing. The chemistry of the carburizing reactions are briefly discussed. Advantages claimed for the process are close control by rapid analysis of gases drawn from the muffle, decreased cost from fuel and labor saving, and high rate of carburizing. WLC (10c)

Mechanism of Energizer Action in Carburization. R. A. RAGATZ & O. L. KOWALKE (University of Wisconsin). *Metals & Alloys*, Vol. 2, Dec. 1931, pages 343-348.
29 references. The authors discuss carburization with pure C on a physicochemical basis. The relations of partial pressures of CO and CO_2 at the C and steel surfaces are shown schematically. Current theories regarding the action of energizers are discussed. The evolution of CO_2 from the decomposition of carbonates as an explanation of the energizing action is shown to be erroneous. A theory is presented which states that a metal oxide whose power for absorption of CO_2 at the temperatures of carburization is sufficient to maintain a carburizing atmosphere at the steel surface will energize the carburizing process. Metal oxides or carbonates such as $CaCO_3$ and $MgCO_3$ which do not have this power will not energize carburization. The extreme energizing action of alkali carbonates, Li, Na, and K, is explained by the formation of some metallic vapor at the carburizing temperatures which is more effective as a CO_2 scavenger than the oxide. Ba and Sr oxides are not reduced to metal at carburizing temperatures but the oxides have a powerful scavenging action on the atmosphere, removing CO_2. A substance capable of catalyzing the C : CO_2 : CO reaction will energize carburization which accounts for the action of Ni, Co and Fe and other substances that have been found to have an energizing effect. Carbonate is not an essential constituent of an energizer. WLC (10c)

Selective and Localized Nitriding. Part VII of Nitriding of Steel and Iron Base Alloys. WM. J. MERTEN. *Fuels & Furnaces*, Vol. 9, Nov. 1931, pages 1243-1250.
Parts of the surface of fabricated articles can be protected from nitriding so as to permit subsequent machining by covers of Ni either held in place mechanically or plated or welded on. An electroplate less than 0.0005" thick is sufficient. Sn gives similar protection but most other metals and many non-metallic materials seem to promote the nitriding catalytically. Nitrided articles may be denitrided in a fused sodium-potassium chloride bath (50/50 ratio), thus permitting changes or additional machining. The denitriding is not disadvantageous to a subsequent renitriding. CMB (10c)

The Heat of Formation of the Nitrides II. The Nitrogenization Heats of Lithium, Aluminum, Beryllium and Magnesium. (Die Bildungswärmen der Nitride II. Die Azotierungswärmen von Lithium, Aluminium, Beryllium und Magnesium.) B. NEUMANN, C. KROEGER & H. HAEBLER. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 204, Feb. 9, 1932, pages 81-96.
The heat of formation was measured directly by heating the metals with N; the tests are described in detail. The heats of formation in cal. per mol were determined as follows: Li_3N 47,166, AlN 57,400, for Be_3N_2 133,470, and Mg_3N_2 116,000. The nitrogenization products dissolve only partly in water. In presence of Li_3N Fe, Ni and Co absorb more N than in the pure state. Ha (10c)

Nitriding Process in the Heat Treatment of Steel. H. M. GUSTAFSON. (General Electric Co.). *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1136-1139.
Paper read Sept. 11, 1931, before the Northwest Section, Society of Automotive Engineers. Explains nitriding process and discusses properties of the nitrided surface, furnaces used and history of the process. By nitriding the cylinders in the motor block, one automobile manufacturer has reduced their wear 20 to 1. Maximum resistance to corrosion is exhibited by the unpolished surface. As nitrided steel remains file hard to 1200° F., it is ideal for applications requiring high wear resistance at comparatively high temperatures. Electric furnaces are especially suitable for nitriding. There are 2 types, the box type and the vertical cylindrical type. A late development is the addition of sulphur to the composition. It is claimed that machinability is improved greatly without impairing other properties. Maximum surface hardness and case depth are obtained by a heating period of about 40 hr. Increasing the pressure of NH_3 considerably increases the depth of the case and also tends to decrease the surface hardness if the heating cycle is longer than 25 hrs. MS (10c)

JOINING OF METALS & ALLOYS (11)

Modern Methods of Soldering and Welding and the Testing of the Seams. (Neuzeitliche Löt-und Schweissverfahren und die Nachprüfung der erzeugten Nähte.) H. KLOPSTOCK. *Werkstattstechnik*, Vol. 25, Mar. 1, 1931, pages 131-135.
Methods for soldering and welding materials are described which permit joining all metals both with each other as with one another, and to repair defective castings. Recent processes of welding are described which give a higher welding speed and economy. A testing instrument which removes small parts of the soldered or welded part is described to test the quality of the seam. Ha (11)

Gas-Welded and Brazed Joints for High Nickel Alloys. F. G. FLOCKE, J. G. SCHOENER & R. J. MCKAY. *Paper presented to the 32nd Annual Convention of the International Acetylene Association*, Chicago, Nov. 1931, 6 pages; *Welding*, Vol. 3, Feb. 1932, pages 79-83, 91.
The use of the oxy-acetylene flame in joining Monel metal, pure Ni and Inco Cr-Ni is entirely practical for a variety of seams and forms of metal. The 3 essentials necessary to the satisfactory completion of a welding job are: (1) Correct materials—which includes welding rod, flux and material to be welded, (2) Proper setting up of a job which includes jigging so as to hold the work in place during welding, (3) Proper procedure. These essentials are well explained by the authors and concrete examples of the various types of welds are given. Proper methods of silver soldering and brazing of these alloys are also explained. Ha + TEJ (11)

The Jointing of Aluminium. *Metallurgist*, Apr. 1931, pages 60-61.
An extended abstract of a paper by U. Magnani & C. Panseri in *La Metallurgia Italiana*, Vol. 23, Feb. 1931, pages 85-101. See *Metals & Alloys*, Vol. 2, July 1931, page 132. VVK (11)

Some Practical Notes on Joining Aluminium. A. J. T. EYLES. *Engineer*, Vol. 152, Dec. 11, 1931, pages 618-621.
A practical article discussing the following methods of joining Al: soldering; welding; with a discussion of welding materials, cast welding, pressure welding, hammer welding, and electric welding; riveting, threading Al joints; flanging and seaming. A table is given enumerating the various fluxes used for Al welding and photographs are given showing examples of riveted and spot-welded material. LFM (11)

Comparative Loading Tests of Welded, Riveted, and Bolted Steel Floor Panels. FRANK P. MCKIBBEN. *General Electric Review*, Vol. 35, Feb. 1932, pages 107-109.
Comparative tests under similar conditions of loads showed the deflections least with the welded floor, the riveted next, and the bolted last. Concentrating a load of 8000 lbs. on 1 ft.^{2} of 1 span indicates again the least deflection for the welded floor. WHB (11)

Brazing (11a)

The Brazing of Hard Metals. (Widia) [Ueber das Löten von Hartmetallen (Widia).] C. AGTE & K. SCHROETER. *Werkstattstechnik*, Vol. 25, Aug. 1, 1931, pages 373-374.
In brazing the tips of hard metals to holding shanks the metal is to a certain extent changed; the amount of change is investigated for several brazing agents. The changed surface can be easily removed by grinding. Ha (11a)

Some Practical Notes on Solders and Soldering Fluxes. A. EYLES. *Metal Industry, London*, Vol. 40, Jan. 1932, pages 3-6.
Tables list the fluxes and compositions of solder to be used for various metals when soldering or brazing. Impurities, tools and methods are discussed. PRK (11a)

Can Brazing be Considered as a Satisfactory Means of Construction or Joining? (Kann die Härtlötung als einwandfreies Konstruktions oder Verbindungselement betrachtet werden?) A. KRAUSS, H. V. OTHEGRAVEN & F. WECKWERTH. *Schmelzschweissung*, Vol. 11, Jan. 1932, pages 20-21.
In connection with the article by Weckwerth (*Metals & Alloys*, Vol. 2, Jan. 1932, page MA 16) a few controversial points are discussed, especially the value of and the influence of the flux on the soldered parts. Borax is generally considered to be harmful. Emphasis is laid on proper after-treatment and a slight excess of oxygen in flame. Ha (11a)

Practical Experiences with Robusco Cast-Iron Brazing. (Erfahrungen aus der Praxis über Robusco-Gusseisen-Hartlötung.) FRIED. H. FLIESS. *Schmelzschweissung*, Vol. 11, Feb. 1932, pages 36-39.
The difficulties of welding of cast-iron due to inner stresses and formation of graphite are discussed and it is pointed out that often the preparation of the piece and the time spent is out of proportion to the value of the work. In such case hard soldering (brazing) with Robusco-bronze is recommended which, as tests have shown, produces a reliable joint which can be made at lower temperature and penetrates the metal readily to make a uniform joint. This is illustrated by micrographs. Ha (11a)

Welding & Cutting (11c)

The Oxy-Acetylene Welding of Copper Fire-Boxes of Locomotives. L. SACCOMANI & R. VERZILLO (Engineers to the Italian State Railways.) *Welding Journal*, Vol. 28, Dec. 1931, pages 371-373; Vol. 29, Jan. 1932, pages 11-13; Feb. 1932, pages 51-54; *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 28-30.
The authors give reasons for difficulties encountered in welding Cu. Results of tests show that Cu welds made with electrolytic Cu filler without flux are satisfactory, having a tensile strength of approximately 21 kg./mm^2 and elongation of approximately 30%. Many Cu fire-boxes have been repaired by this method and several all-welded Cu fire-boxes built under careful procedure control. Welds are kept under close observation while in service. Part II. Cracks and splits in Cu fire-box sheets can be repaired by oxy-acetylene welding, using pure electrolytic Cu as filler. Cu bars thus welded show a tensile strength of approximately 21 kg./cm.^{2} and elongation of approximately 30%. Careful inspection of many repaired fire-boxes at frequent intervals has shown that this method of repair is satisfactory. Several all-welded Cu fire-boxes have been in service since 1927. The authors describe the welding technique necessary for this type of work. This third installment includes data on physical properties of oxy-acetylene welded Cu bars and comparative cost analyses of fire-box repairs made by welding and riveting. The authors show the economy of the use of welding in repair and construction of Cu fire-boxes. TEJ (11c)

Coal Mine Equipment Built by Welding. Joseph C. Coyle (Pikes Peak Fuel Co.). *Welding,* Vol. 2, Nov. 1931, pages 751-753.

The manufacture of truck and trailer bodies, trailer chassis, metal bins and chutes, sprags for mine cars and various other articles has made electric and oxy-acetylene equipment a profitable investment for this coal mining company. TEJ (11c)

Hot Welding for Speed and Quality. Gilbert E. Doan (Lehigh Univ.). *Metal Progress,* Vol. 21, Jan. 1932, pages 56-61.

A brief discussion of the physical chemistry and metallography of electric arc welding. Higher welding temperatures are made possible in modern practice by the use of cellulose covered wire. The combustion of the covering produces a reducing atmosphere which prevents the formation of the metallic oxides ordinarily occurring at the elevated temperatures required to attain a weld of high ductility. Ductility of low temperature welds is decreased by rapid solidification before occluded gases have an opportunity to escape. WLC (11c)

Strong Tough Welds Made Rapidly. Gilbert E. Doan (Lehigh University). *Metal Progress,* Vol. 21, Feb. 1932, pages 39-43.

A summary of the advantages of modern "hot" welding processes. The increased ductility and higher endurance limit of the coated electrode welds seems to be due to blanketing the metal from gases of the atmosphere and keeping the weld molten long enough for entrapped impurities to float out and escape. Peening and annealing of weld metal is discussed. WLC (11c)

All Welded Switching Locomotives. R. V. Devlin (General Electric Co.). *Welding,* Vol. 2, Dec. 1931, pages 813-815.

A description of recently completed Diesel-electric switching locomotives of which truck frames, underframes and cab structures were fabricated from structural shapes by arc welding. TEJ (11c)

Repair of Boiler by the Approved Welding Methods. (Dampfkesselreparaturen durch Anwendung der zugelassenen Schweissverfahren.) F. A. Birke. *Die Wärme,* Vol. 54, Mar. 7, 1931, pages 175-179.

Recent advances of boiler repair welding are recognized with reference to the physical properties of the seams. The elimination of stresses in electric arc welding and the large economical savings due to the application of welding are emphasized. The danger of boiler explosions owing to improper welding and the authoritative specifications and regulations are discussed. The experience gained on the repair welding of several boilers is considered and the results presented in 13 illustrations. EF (11c)

Welding Method Reduces Crusher Repair Costs. *Engineering & Mining Journal,* Vol. 131, June 22, 1931, page 560.

At the Moctezuma Copper Co. plant at Nacozari, Sonora, Mexico, crusher repair costs have been reduced by use of a new method on worn mantles of No. 8 McCully crushers. The new method of welding features the use of short manganese rods, curved to fit the circumference of the crusher mantles, which are welded carefully first to the worn mantle surface and then to each other, until the original mantle surface is restored. The procedure effects a 50% reduction in time, power and welding material. WHB (11c)

A Consulting Engineer Looks at Structural Welding. G. D. Fish. *Steel,* Vol. 88, Mar. 19, 1931, pages 34-35-38.

Advantages and economy obtained are enumerated and a general outline of the best procedure is given. Ha (11c)

The Welding Contractor in Steel Construction. Gilbert D. Fish. *Welding,* Vol. 2, Dec. 1931, pages 799-801.

Factors which are hindering the progress of welding contractors are: (1) lack of structural engineering knowledge; (2) unfamiliarity with the cost elements of steel construction, not excepting the welding itself; (3) absence of coöperation in group activities. The author believes that welding contractors have an opportunity to entrench themselves in the business of field welding for buildings; their success depends on efficiency and on establishing a reputation for reliability. TEJ (11c)

Welding Stainless Steel Sheets. A. Eyles. *Sheet Metal Worker,* Vol. 22, Nov. 13, 1931, pages 648-649.

The principal points for obtaining good welding results either with gas or electric arc-welding are briefly discussed, and a few examples are illustrated. Ha (11c)

New Welded Type Rail Bonds Interchangeable for Arc Welding and Gas Welding. H. H. Febrey. *Iron and Steel of Canada,* Vol. 15, Jan. 1932, pages 1-2.

An article accompanied by 5 figures describing a new type of rail bond which has the advantage of being applied readily with the oxy-acetylene flame or metal arc welding. The terminals in these new bonds are of solid steel butt-welded to the conductors and sleeves. The bonds are made by cutting the conductor to proper length, attaching split steel ferrules at each end, and then flash-butt-welding the parts together. OWE (11c)

Modern Electric Resistance Welded Pipe. J. S. Adelson & L. B. Grindlay (Republic Steel Corp.) *Journal American Welding Society,* Vol. 10, Nov. 1931, pages 9-13.

Paper presented at joint meeting of the Metropolitan Sections of A.S.C.E., A.W.W.A., and A.W.S., June 9, 1931. The authors describe the method of manufacture, physical characteristics of the product, tests applied to the welded pipe and some of its uses. Photographs of tests and photomicrographs of weld and base metal are included. TEJ (11c)

On the Cause of Boiler Failures. (Ueber die Ursachen von Dampfkesselschäden.) O. Bauer. *Die Wärme,* Vol. 54, July 25, 1931, pages 567-574.

Among the various causes responsible for the failure of boilers in service the following ones are discussed at length: the properties of the materials employed, the heat dissipation and manner of operation, and the type of the steam plant. In the second part of the lecture delivered before the Vereinigung der Grosskesselbesitzer, Dresden, 1931, instructive examples of imperfect welding work on boilers are given. The speaker critically discusses the potentiality of repair work performed by welding and touches upon the principal non-destructive testing methods for welded material. EF (11c)

Welding Testing Methods. (Prüfverfahren für Schmelzschweissungen.) K. Adloff. *Die Wärme.* Vol. 54, Nov. 23, 1931, pages 894-895.

Reviews the present state of both destructive and non-destructive testing methods in the fields of welding. EF (11c)

Survey of the Erecting of Collecting Tubes and Sectional Chambers. (Bauüberwachung von Sammelrohren und Teilkammern.) E. Block. *Die Wärme,* Vol. 54, Apr. 25, 1931, pages 322-325.

Experiences gained on the joining of the various parts of boiler systems are collected in this lecture delivered at the Meeting of the Zentralverband der Preussischen Dampfkessel Überwachungsvereine, 1931. EF (11c)

Oxwelding Speeds Repairs in the Power Plant. R. W. Boggs. *National Engineer,* Vol. 35, June 1931, pages 199-200.

Description of a few cases where savings in time and cost were obtained in repairing and dismantling of equipment. Ha (11c)

Development and Application of Fusion Welding in Pressure Vessels. C. A. Adams. *Boiler Maker,* Vol. 31, July 1931, pages 188-190; Aug. 1931, pages 217-218.

In an address before the American Boiler Manufacturers Association, an outline of the development of the various fusion-welding processes and their application is given with particular reference to pressure vessel construction. The methods for non-destructive tests of welded joints are discussed. Ha (11c)

Suggestions on the Thermit Welding of Rails. (Anregung zum Ausbau des aluminothermischen Zwischengussverfahrens für Schienenschweissungen.) D. I. Brewitt. *Organ für die Fortschritte des Eisenbahnwesens,* Vol. 86, Apr. 15, 1931, pages 200-201.

Referring to a previous paper of Reiter (See *Metals & Alloys,* Vol. 2, Apr. 1931, page 82 and Vol. 2, Nov. 1931, page 265) the author gives some additional information and furnishes some suggestions on the alumino-thermal welding of rails. Ha + EF (11c)

Rail Welding. (Das Aufarbeiten von Schienen.) Th. Wuppermann. *Organ für die Fortschritte des Eisenbahnwesens,* Vol. 86, Aug. 1, 1931, pages 327-329.

Feeling that electric resistance welding (butt welding) has not been adequately covered in a previous publication of Reiter on "The Present Status of Rail Welding" (See abstract above), the writer gives some supplementary knowledge on the subject. EF (11c)

The Mechanical and Structural Characteristics of Welds made by the Electric Arc with Standardized Types of Structural Steel. (Die mechanischen und Gefüge-Kennzeichen der im elektrischen Lichtbogen hergestellten Schweissen bei genormten Stahlsorten für Konstruktionen.) Blasic & Guglielmino. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Dec. 4, 1931, page 923.

The question is discussed in how far normal profiles can be used for building up machine by welding. Values found in experiments for the welds ranged between 36 and 94 kg./mm.^{2} for tensile strength and 120 and 380 Brinell hardness. Ha (11c)

The Conception in Foreign Countries Concerning the Welding of Boilers and Pressure Vessels. (Einstellung des Auslandes zur Schweissung an Dampfkesseln und Druckgefässen.) E. Block. *Die Wärme,* Vol. 54, Nov. 28, 1931, pages 895-897.

The author summarizes the tendencies in the fields of welding pressure vessels and boilers with reference to the following countries: U. S. A., England, France, Italy, Switzerland, Poland and Belgium. EF (11c)

Arc Welded Construction Helps Insure District Heating Service. E. R. Benedict. *Heating & Ventilating,* Vol. 29, Jan. 1932, pages 50-51.

Arc welded piping has been found to have a tensile strength of over 60,000 lbs./in.^{2}, with the result that strong and desirable welds are obtained. From a contracting point of view also the use of arc welding results in economy and utility in the field. WAT (11c)

Rules for Fusion Welded Construction of Boilers and Pressure Vessels As recently adopted by the A.S.M.E. *Journal American Welding Society,* Vol. 11, Jan. 1932, pages 9-18.

The new rules make no reference to the method or process of applying the welding and undertake to regulate the quality of the welding only by critical tests of the finished product. The rules for welding pressure vessels are divided into three classes, based upon the intended use of the vessel. Class 1, which represents the highest type of construction is absolutely without limit as to size, working pressure or the contents. The requirements for this class, which are identical with those for construction of steam boiler drums, contain the most rigid safeguards relative to the application of the welding process. Tension tests, bend tests, specific gravity tests of weld metal, X-ray, hydrostatic and hammer tests are required for this class of construction. All Class 1 fusion-welded vessels shall be stress relieved. Class 2 provides for vessels with a maximum plate thickness of 1½", which are not to carry lethal gases or liquids, or be subjected to as severe conditions of service as those built under Class 1. Class 2 vessels must not carry liquids at a temperature of 300° F. or above, and the maximum operating pressure and temperature in this class are 400 lbs./in.^{2} and 700° F. Tests required for Class 2 are tension, nick-break, bend and hydraulic-hammer. Class 3 provides for vessels with a maximum plate thickness of ⅝", which are not to carry lethal gases or liquids, or be used for storage of gases or liquids at any temperature materially exceeding their boiling temperature at atmospheric pressure. The maximum pressure and temperature permitted in this class are 200 lbs./in.^{2} and 250° F. Tests required for Class 3 vessels are, tension, bend and hydrostatic-hammer test. Also included are permissible designs for welded head attachments and welded nozzle construction for pressure vessels. TEJ (11c)

WORKING OF METALS AND ALLOYS (12)

Melting & Refining (12a)

Surface Films. *Metallurgist,* Dec. 1931, pages 177-178.

The surface films referred to in this article are those formed on molten metals during melting, alloying and casting. The film formed on Al while protecting it from rapid dissolution when molten also introduces difficulties in melting scrap and in preventing the escape of H and other gases from the bath. This property of film formation on molten Al is also present in alloys containing as little as 2 or 3%. This film is probably not truly a thin layer of Al_2O_3 but is "diluted" either by quantities of the metal itself or possibly by the presence of some sub-oxide. With metals similar to Al, the behavior varies. Mg forms no continuous and adherent surface film either in the solid or the liquid states. Mg is also free from difficulties arising from the retention of gas and also does not confer film-forming properties on Cu and other alloys to which it is added. Be appears to form a particularly strong surface film both in the solid state and in the liquid condition. In spite of the fact that Be is chemically even more active than Al or Mg, the polished surface of the metal retains its brightness for a long time owing to the formation of a surface film and some similar properties appear to be conferred upon certain of its alloys. On the other hand, the surface film which is formed on alloys either of Cu or of steel, which contain only small amounts of Be is exceedingly tough and makes it difficult in some instances to melt down scrap from these materials. VVK (12a)

Remelting of Aluminum Scrap and Waste Metal. (Das Umschmelzen von Aluminiumspänen und Krätzen.) E. R. Thews. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Jan. 10, 1932, pages 25-26.

The article outlines the practice to be followed in remelting aluminum scrap. The scrap should be freed from oil, the iron parts should be separated by magnetic separators. Briquetting of the scrap is advisable in order to avoid losses through oxidation. Three various methods of remelting are described and data are given on the slags and fluxes to be used in remelting. GN (12a)

Experiences of Operation of Basic Bessemer Mills (Erfahrungen im Thomasbetrieb). *Stahl und Eisen,* Vol. 51, Dec. 17, 1931, pages 1561-1569.

Report 219 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The paper represents the discussion following the presentation of the Paper on "Dimensions and Operation of German Thomas Converters" in *Stahl und Eisen,* Vol. 51, Sept. 3, 1931, pages 1105-1134; Sept. 10, 1931, pages 1136-1148. The results of the discussion are summarized under the main headings: (1) mixers and operation of mixers; (2) dimensions, lining and preparation of lining of converters; (3) operation of converters, such as composition and weight of charge, metallurgical reactions with special reference to the effect of nitrogen, composition, amount and properties of slag, pouring practice and output. GN (12a)

Making Steel Castings by the Open Hearth and Bessemer Processes. (Herstellung von Stahlformguss in der Martingiesserie und Kleinbessemerei.) H. Springkämper. No. 16 in H. Hermann's series "Die Betriebspraxis der Eisen-Stahl- und Metallgiesserei. Wilhelm Knapp, Halle (Saale), 1932. Paper, 6¼x9¼ inches, 87 pages. Price 7.50 RM.

This small treatise gives a general introduction to the subject, but does not go into great detail on any topic. Few references are given, and the treatment as a whole is a bit sketchy, more suited to give a student a general idea of steel foundry practice than to add much to the knowledge of the practising foundryman. It deals with small open-hearth furnaces (12 tons) and producer gas equipment for firing them, with small (2 tons) converters, with refractories, with pattern design, gating, shrinkage, cracking, rates of cooling, heat-treatment, and with sand blasting.

Cast steels mentioned for wear resistance are

C	Si	Mn	Cr
.40	1.50	.50	—
.50-.55	1-1.20	.80	—
.50	.40	.70	1.10
.40	.35	.80	1.00, while .70 C, .70 Mn, 1.0 Si,

1.4 W is advocated for Pilger rolls. Ni Mo steels are cited as useful for high temperature service.

Brief sections on testing, on cost calculation, and a two-page index complete the book. Electric steel foundry practice is not covered, but another volume in the series is in preparation which will deal with this. H. W. Gillett (12a)-B-

The Effects of the Products of Combustion on the Shrinkage of Metal in the Brass Industry. C. Upthegrove & A. J. Herzig. *Engineering Research Bulletin,* No. 22, *University of Michigan,* Department of Engineering Research, Dec. 1931, 66 pages.

The investigation had as its objective: first, the determination of the mechanism by which the products of combustion affect the shrinkage of brass; second, the application of the results obtained to commercial melting procedure; third, the study of the effect of various fluxing agents on the metal losses in the furnace. Shrinkage in the melting operation occurs either by volatilization or by oxidation of the alloying constituents. In the first case, the loss is through the stack, while in the second, it is represented as dross or skimmings. Whether or not the loss is primarily by volatilization or by oxidation will be determined by the composition of the metal and by the nature of the furnace atmospheres. In the melting of metals, in which volatilization losses predominate, a slightly oxidizing atmosphere may be used to provide protective layers which will result in a lowering of the metal shrinkage. In the melting of metals with predominating oxidizing losses, a neutral or reducing atmosphere may be used to keep shrinkage down to the minimum. The use of fluxes as a means of lowering the shrinkage of the metal must be based on the same considerations as hold for the lowering of metal shrinkage by furnace-atmosphere control. A flux showing very satisfactory results in producing a lowering of the metal shrinkage is developed. Ha (12a)

Casting & Solidification (12b)

Cooling and Solidification of Liquid Metal. *Foundry Trade Journal*, Vol. 45, Oct. 29, 1931, page 271.

A brief discussion of a mathematical investigation of the cooling and solidification of liquid metal by Carl Schwarz is given. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 18 and Feb. 1932, page MA 44. OWE (12b)

The Melting and Casting of Magnesium Alloys. Edmund B. Thews. *Canadian Chemistry & Metallurgy*. Vol. 16, Mar. 1932, pages 68, 70, 73.

The melting and casting of Mg is not as difficult as the melting and casting of Al when due consideration is paid to the following characteristic properties of Mg alloys: (1) their tendency to oxidize or to burn in contact with air or moisture, their very low specific weight, and their explosive reaction with moisture. Melting and pouring operations are outlined and fluxes discussed. The latter consist chiefly of $MgCl_2$ mixed with other chlorides or fluorides. Precautions noted are: proper facility for release of air and gases from molds, cooling rings and chill plates avoid cooling strains in heavy casting molds. Graphite pastes change the metallic character of the cooling surfaces to reduce explosive tendencies. Molds should be filled quickly. WHB (12b)

Composition of Steel Mill Molds. (Über die Zusammensetzung von Stahlwerkskokillen.) *Die Metallbörse*, Vol. 21, Oct. 18, 1931, pages 1866-1867; Oct. 24, 1931, pages 1898-1899.

Analyses of some 17 molds of American, German, English, Belgian, Austrian and French origin are given showing a great variety of composition. The effect of C, Si, Mn, S, P, Ni, Cr on wear of iron and steel molds is discussed. EF (12b)

Comparative Fluidity Tests. (Vergleichende Giessbarkeits-Versuche.) Ernst Scheuer. *Metallwirtschaft*, Vol. 10, Nov. 20, 1931, pages 884-885.

The apparatus used was similar to that developed by Guillet and Portevin, in which the metal is cast under definite conditions at constant hydrostatic pressure into a spiral shaped mold. The fluidity is measured by the length of the mold which is filled out with metal. The fluidity of Zn, Al and silumin increases proportionally with the pouring temperature. Mold temperature has little influence up to 300° C.; above that it increases the fluidity. The smoothness of the mold surface has practically no influence. The fluidity of the binary alloys Al-Si, Al-Cu, Al-Zn and Al-Ni was investigated. In each case, small additions of the respective metals lower the fluidity of pure Al. With further additions it rises again, approximately up to the eutectic point, after which it remains almost constant. Additions of Cd and Ni up to 1.5% to silumin raise its fluidity about 10%. Mg, Cu, Zn and Mn have little or no effect. Additions of Mg up to 2% to a 13% Al-Cu alloy lower the fluidity slightly, further additions raise it. The lowered fluidity is explained by the formation of a solid solution, and the increase with higher additions by the formation of a eutectic. CEM (12b)

On the Residual Strain of the Grey Iron Castings. S. Matoba & H. Kishimoto. *Kinzoku-no-Kenkyu*. Vol. 9, Feb. 1932, pages 74-84.

The gray iron castings having simple geometrical forms were made as to cool in different velocities in different parts. By measuring the elastic strain due to the initial stress remaining them, it was found that the amount of residual strain is practically proportional to the difference of mean cooling rate from the pouring temperature to a temperature at which the stress begins to be provoked, and is independent of the mode of cooling thereafter. The casting stress or the mechanism of growing the initial stress in the casting was formerly elucidated only qualitatively by Martens and Heyn. In the present work, however, the strain was quantitatively measured and further extention was made to their explanation. And it was also found that the amount of residual strain is minimized by making the temperature uniform during cooling at every part in the casting. The residual strain of gray iron casting can be eliminated by annealing as cold worked steel. The annealing is nearly complete when the casting is heated to 600° C. for 1 hour. HK (12b)

The Solidification of Steel Ingots. B. Matuschka. *Rolling Mill Journal*, Vol. 5, Oct. 1931, pages 643-646.

See *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 73. Ha (12b)

Steel: The Casting of the Ingot. (L'Acier: La Coulée le Lingot). Marcel Guedras. *Aciers Spéciaux, Métaux, et Alliages*, Vol. 6, Sept. 1931, pages 463-464; Dec. 1931, pages 657-659.

A critical study about molds and ingots. The shape of molds is considered rather generally. Then the casting temperature is discussed. This temperature is greatly responsible for the formation of "ghost lines." Author recommends as the temperature for casting about 100° C. higher than the melting point of steel or alloy steel. GTM (12b)

The "Runnability" of Electric Steel (La colabilità dell acciaio elettrico). U. Gabino. *La Metallurgia Italiana*, Vol. 24, Mar. 1932, pages 187-191.

The Cury fluidity spiral has been modified so as to require less metal. The cross section of the spiral is a trapezoid 5 mm. at the bottom, 10 mm. at the top, 8 cm. high. It is 1 m. long, with 20 divisions, 5 cm. apart, gated in the center of the spiral, with a small basin below the sprue. Common dry sand, synthetic dry sand, clay bonded, and green sand with 1% dextrin all gave about the same length of spiral, while green sand without dextrin, with 4% moisture gave a much shorter spiral. Mold coatings do not notably affect the length. The normal amount of Si is necessary to obtain suitable runnability. Ordinary variations in composition do not have much effect. The temperature of the steel is the most important variable. The length of the spiral varies, by practically a straight line relationship, from 7 divisions at 1490° C. to 14 at 1550° C. The spiral has been found very helpful in steel foundry operation. HWG (12b)

The Freezing of Steel Ingots. J. Cunningham. *Metallurgia*, Vol. 5, Apr. 1932, pages 199-200.

Reviews the mathematical treatment of solidification of ingots reported by the Steel Committee of the Verein deutscher Eisenhüttenleute in the *Archiv für Eisenhüttenwesen*. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 18; Feb. 1932, page MA 44. JLG (12b)

Rolling (12c)

Roll Pass Design. Part XXVIII. W. Trinks (Carnegie Inst. of Technology). *Rolling Mill Journal*, Vol. 5, Apr. 1931, pages 261-264, 267-268.

Gives complete table of data on gothic passes employed in roughing rolls of hand mills, with a section by section analysis of a single gothic pass. These passes are usually rolled zig-zag fashion and the reductions are not very heavy. The use of diamond passes in continuous billet mills is also described. Tables of data are given on the diamond-square-diamond reduction method for the production of square sections by alternate diamond and square passes. JN(12c)

Resistance to Deformation and Flow of Metal in Rolling. Part II. Erich Siebel. *Rolling Mill Journal*, Vol. 5, Apr. 1931, pages 269-270, 296.

A report of the Rolling Mill Committee of the German Iron and Steel Institute, translated from *Stahl und Eisen*. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 270. The author furnishes a set of graphs with a short discussion showing the effect of rolling temperature on the resistance to deformation of ordinary mild steel for reductions from 10 to 50% and for thickness ratios of 11.2%, 5.6% and 2.8%. JN (12c)

New High Capacity Rolling Mills for Foreign Order. (Neue Hochleistungswalzwerke des Auslandes.) *Die Metallbörse*, Vol. 21, Sept. 12, 1931, page 1707.

Data on rolling mills recently designed in Germany for foreign order (Russia) are given referring to 5 different blooming mills. In conclusion the writer mentions an American built rolling mill of the "cross country type." EF (12c)

The Operating Organization in the Rolling Mill with Special Regard to the Program of Work. (Die Betriebsorganisation in einem Walzwerk unter besonderer Berücksichtigung der Arbeitsvorbereitung.) Kurt Wiecke. *Stahl und Eisen*, Vol. 52, Jan. 28, 1932, pages 77-84.

Report 91 of the Rolling Mill Committee, and Report 54 of the Committee on Economy of Operation of Verein deutscher Eisenhüttenleute, and presented at meeting Sept. 29, 1931. Includes 14 diagrams. A paper on economy of operation which may be obtained by preparation of an outline of the work to be done. This preparatory outline for a rolling mill may be divided into 5 main groups: (1) outline of rolling program; (2) preparation of intermediate materials; (3) preparation for operating crews; (4) preparation for rolling; (5) final working instructions. In addition, it is shown how, with help of few and simple notes, to draw up technical and cost accounting figures, which make possible careful and thorough operating supervision. By means of correct figuring of daily costs a satisfactory pre- and post-accounting is developed, which serves the operator as well as a necessary set of tools. DTR (12c)

Bearings in Rolling Mill Housings. C. Rademacher. *Domez* (Achievements of Metallurgy in USSR and Abroad), No. 10, 1931, pages 38-46.

Mechanical details and principles involved in the service of bearings for roll necks are described. (12c)

Design Principles for Mill Tables. A. B. De Salardi. *Rolling Mill Journal*, Vol. 5, Aug. 1931, pages 547-550; Oct. 1931, pages 661-662, 674; Dec. 1931, pages 779-782, 791-792.

Formulas for the calculation of the individual parts of mill tables and the necessary driving power are developed. Formulas for the design of gears and bearing parts are derived from the torque-effect of the impact between bar and roller. Ha (12c)

Developments in Steel Mill Drives. John Liston. (General Electric Co.). *Rolling Mill Journal*, Vol. 6, Jan. 1932, pages 13-14, 30.

Excerpt from General Electric Review, Jan. 1932. Describes several drives which were built and installed during 1931. MS (12c)

Metal Lubrication and Roll Cooling in Aluminum Hot-Mill Practice. Robert J. Anderson. *Iron Age*, Vol. 128, Dec. 31, 1931, pages 1674-1677.

Lubrication of ingot surface is necessary to prevent slabs from sticking to the rolls, to increase tendency of rolls to bite and to prevent slabs from curling. Various lubricants have been used, such as kerosene, light machine oil, transformer oil, cup grease and water oil mixtures. Discusses the relative merits of these and the practice of some American and European plants. VSP (12c)

Electrical Developments in Rolling Mills for 1932. C. P. Croco. (Westinghouse Electric & Mfg. Co.). *Rolling Mill Journal*, Vol. 6, Jan. 1932, pages 11-13.

Outlines developments in the application of electrical drives to rolling mill equipment and describes briefly several installations. MS (12c)

The Manufacture of Seamless Tubes. Wm. H. Engelbertz. *Rolling Mill Journal*, Vol. 5, Apr. 1931, pages 243-246.

A description of the Pilger or Mannesmann Mill process, the semi-automatic process, and the push bench process for the production of seamless steel tubes with a discussion of output capacities of each process per 8 hr. shift. JN (12c)

The Composition of Modern Roll Metals. Part II. John Hruska. *Rolling Mill Journal*, Vol. 5, Apr. 1931, pages 265-267.

The author gives the analytical composition of chilled and unchilled high-carbon steels used in the manufacture of rolls for high-speed rod mills, with scleroscopic determinations on the former. He also gives the analysis of rolls made of pearlitic manganese steel and of high-chromium steel used in cold rolling. He discusses the special advantages of rolls made from Mo alloy steels and the heat treatment required for rolls containing Mo, Ni and Cr. JN (12c)

Sheet and Tinplate Rolls: An Investigation into the Roll Loads, Stresses, and the Causes of Roll Breakage. J. Selwyn Caswell. *Proceedings, South Wales Institute of Engineers*, Vol. 46, Jan. 14, 1931, pages 813-834; Vol. 47, Apr. 10, 1931, pages 109-140; Vol. 47, Sept. 15, 1931, pages 367-373.

Discussion of article abstracted in *Metals & Alloys*, Vol. 2, Jan. 1931, page 11. AHE (12c)

Sheet and Tinplate Rolls. J. Selwyn Caswell. *Blast Furnace & Steel Plant*, Vol. 19, Nov. 1931, page 1490; Dec. 1931, page 1592.

Parts of a serial abstract published in Proceedings South Wales Institution of Engineers, Vol. 46, pages 312-452. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 11. MS (12c)

Inclusions—Their Effect, Solubility and Control in Cast Steel. C. E. Sims & G. A. Lillieqvist (American Steel Foundries.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 453, Feb. 1932, 24 pages.

From an extended series of observations it was found that there was a direct relationship between the distribution of inclusions in steel castings and the ductility of the steel. Globular inclusions with a random distribution had a minimum effect on the ductility, while inclusions in a net-work decreased the ductility. In the latter type of distribution the inclusions were probably formed after part of the steel had solidified, and they appear to be part of a eutectic. The net-work distribution was found most frequently in steels that had been deoxidized with Al. As far as could be determined the ductility was independent of the quantity of inclusions. The average size of inclusion was dependent on the size of the casting, increasing with increasing size of casting. It was apparent that the inclusions were soluble in the molten steel. A high FeO content was found to favor the formation of the globular type of inclusion, and thereby a high ductility. This is due to the fact that if the FeO content is low the solubility of the sulphides in the molten steel is increased and they do not separate until the last of the steel solidifies. It is concluded that it is impossible to remove inclusions or to prevent their formation by simple methods because they are soluble in the molten steel. Adding a small amount of Fe ore just before the deoxidizers served to insure the production of ductile castings. 7 references. JLG (13)

The Formation of Draws and Porosity in Castings. (Über die Lunker-und Porenbildung in Gussstücken.) E. Scheuer. *Metallwirtschaft,* Vol. 10, Dec. 18, 1931, pages 947-951.

Contains 5 references. Porosity in castings is due either to shrinkage of the metal during solidification or to the release of dissolved gases in the melt. The two causes are closely related and it is sometimes impossible to determine which of the two is the cause of porosity in a casting. The formation of finely divided shrinkage pores is reduced by a large temperature drop during solidification, by the use of alloys with a small solidification range and small difference in concentration between liquidus and solidus, and by the use of alloys with a small or sufficiently large percentage of eutectic. Most metals dissolve more gases the higher the temperature they are heated to, so that overheating is to be avoided. If the dissolved gases have a chance to escape before the metal solidifies no harm will result, but if the surface solidifies too quickly, gas will be entrapped and gas pockets form. Single large porous places have a greater weakening effect on the casting than a large number of small porous spots, especially if the large hole is in a vital section. Besides weakening the casting porosity may cause leakage in pressure tight castings. A number of casting defects are illustrated. CEM (13)

Hair Cracks on the Surface of Sheets. Erich A. Matejka *Blast Furnace & Steel Plant,* Vol. 19, Nov. 1931, pages 1467-1470, 1472; Dec. 1931, pages 1555-1559.

Includes 21 references. Part of a serial translation from *Archiv für Eisenhüttenwesen.* See *Metals & Alloys,* Vol. 1, Aug. 1929, page 78. MS (13)

Inclusions Cause Majority of Valve Spring Wire Failures. Frank Stones (Eaton Spring Corp.). *Iron Age,* Vol. 128, Nov. 12, 1931, pages 1234-1237.

In correctly heat treated springs which have not been over-stressed, failures are due to the presence of non-metallic inclusions located near some highly stressed area. According to Gillett and Mack, inclusions some distance away from the point of maximum stress need not necessarily cause failure. The 5 principal impurities in commercial steel are sulphides of Fe and Mn, silicates of Fe and Mn and oxide of Fe. 99% of hardened and tempered valve spring wire in use is badly laminated. Ghost lines are associated with inclusions; they are the result of heterogeneity not only of P, but also of S, although it is uncertain whether inclusions are incidental or their direct cause. Surface decarburization is important to the life of springs. The importance for a greater portion of tested material to reduce the risk of breakage is emphasized. A German machine tests 96 valve springs at once. VSP (13)

Oil Well Valves Use High Carbon Stainless Balls. H. T Morton & I. A. Rummler (Hoover Steel Ball Co.). *Metal Progress,* Vol. 21, Jan. 1932, pages 27-31.

Discussion of the effects of mill defects such as seams, hairlines, and the like on localized corrosion and mechanical failure of check valve balls in oil lines. High carbon (1.0 to 1.1%) stainless (Cr 17.0 to 17.5%) steel is used. WLC (13)

Inverse Segregation. *Metallurgist,* Dec. 1931, pages 178-179.

The phenomenon sometimes known as "liquation" but more correctly called "inverse segregation" is described as follows: when an alloy which has a long range of solidification, either as a solid solution or by the formation of eutectic, solidifies, the crystals first formed have the lowest content of alloying elements, with the result that, as solidification proceeds the residual liquid becomes richer and richer in alloyed metals. If this were the whole story the outer parts of the ingot or casting would contain the least of the alloying elements. The reverse is true, ingots sometimes having a much higher content of alloying elements in the outer part than the average content of the entire ingot. Consideration must be given the fact that the mass of crystals and liquid are in constant motion thus upsetting equilibrium conditions. The explanations offered have included the "Soret Effect," which is an attempted equilibrium between two differing concentrations of elements due to a steep temperature gradient in the same liquid or mass, and the presence of gas in the liquid metal forcing liquid metal from the interior to the outside through the interstices remaining between the crystals of the solidified outer zone. VVK (13)

Non-Metallic Inclusions in Steel. J. C. Booth. *Chemical Age,* London, Vol. 26, Metallurgical Section, Jan. 2, 1932, page 1.

A brief review. VVK (13)

Manual of Industrial Chemistry. Vol. 1, Inorganic; Vol. 2, Organic. Edited by Allen Rogers. 5th edition. D. van Nostrand, New York, 1931. Fabricoid, 6 x 9 inches, 1517 pages. Price $13.00.

Rapid changes and advancements in the field of industrial chemistry since the last edition appeared in 1925 have necessitated a new edition of Rogers' *Industrial Chemistry.* Chemists are so familiar with this work that little need be said in introducing it. For students and younger chemists, who may not be acquainted with this standard textbook and manual, it may be stated that each chapter covers a given industry or process, and the various chapters have been written by men who are recognized as authorities in their respective lines. Dr. Rogers states in the preface, "The aim of the authors is not to give undue attention to minor details, but to stress fundamental principles so that the student may get a background knowledge of the subject. The subject matter is essentially descriptive, without, however, omitting the theoretical considerations necessary for a proper understanding of the subject."

The fifth edition in general covers the same field as the fourth edition, but most of the chapters have been revised to bring the subject matter up to date. In many chapters production data and other statistics have been revised. The fifth edition contains 52 chapters and has been written by Dr. Rogers and 41 collaborators. With few exceptions the chapters have been written by the same experts who were responsible for the fourth edition. The chapter on *Water for Industrial Use,* formerly by Herman Stabler and Alfred A. Chambers, is now written by D. D. Jackson and W. D. Turner, both of the Department of Chemical Engineering, Columbia University. *Organic Chemicals and Intermediates,* formerly by Dr. Rogers, has been greatly enlarged by Alexander Lowy, Professor of Organic Chemistry, University of Pittsburgh, and is now titled *Industrial Organic Chemicals and Dye Intermediates. Petroleum Industry,* formerly written by Thos. T. Gray, is now by Gustav Egloff, Universal Oil Products Company. *Soap and Soap Powder* of the fourth edition, by Lincoln Burrows, appears in the fifth edition as *Soap and Soap Products,* by Martin H. Ittner, Colgate-Palmolive-Peet Company. *Resins, Gums, Turpentine, and Shellac,* revised by Dr. Rogers in the fourth edition, now appears under the same authorship as *Resins, Gums, and Turpentine,* while a new chapter, *Shellac,* has been written by A. C. Langmuir. *Sugar,* written by the late G. L. Spencer in the fourth edition, is revised in the fifth edition by Claude S. Hudson, Professor of Chemistry, Hygienic Laboratory, Washington, D. C. *Cellulose Industries,* formerly by Jasper E. Crane, is now written by Gustavus J. Esselen, Consulting Chemist, Boston. The chapter on *Zinc Oxide and Lithopone* has been extended to include white zinc pigments.

In addition to the new chapter on shellac mentioned above several others have been added. *Soda and Allied Industries* and *Electrolytic Caustic and Bleach Industries* have been written by T. P. Hou, Pacific Alkali Works, Tangku, Hopei, China. A new 51-page chapter, *Industrial Instruments and Their Uses* has been prepared by M. F. Behar, Engineering Editor of Instruments. A Chapter, *Solvents and Nitro Cellulose Lacquers,* has been written by D. B. Keyes. The Chapter, *Brewing and Malting, Wine, and Distilled Liquors,* which appeared in earlier editions was deleted from the fourth edition, but again finds its way back into the fifth. The editor states that the material was eliminated from the fourth edition owing to the Eighteenth Amendment of the Constitution, but that demand for a technical treatment of the subject has been so great that a condensed review of the material has been compiled. The editor states that he has attempted "to present the subject from a technical standpoint only, and in no sense as an aid to home fabrication." The chapter, *Dehydrated, Dried and Evaporated Foods, Condensed Foods,* has been omitted from the fifth edition.

In the preface the editor calls for constructive criticisms. Many chapters could be improved by adding footnote references or bibliographies at the end of sections. Of the 52 chapters, 14 contain neither footnote references nor bibliographies and fully half a dozen more contain only 1 or 2 footnotes. It would also be valuable if costs could be stressed more than they are in some chapters.

The paragraph on "concentration," page 10, needs complete revision. The following statements do not correctly describe the processes involved: "In a jig advantage is taken of the principle of Archimedes which states that the rate of fall of fragmental solids through liquids and gases is proportional to their specific gravity and size. When the particles have the same specific gravity the Wilfley table is employed in which cross or back washing is carried out. Flotation takes advantage of the affinity of certain substances for oils, greases and gases, and the repulsive effect of the same substances on the tension of a water surface."

The chapter on *General Processes* has not been so well brought up to date as some other chapters. A notable omission under "grinding" is the Symons cone crusher. The author includes all types of crushing and grinding under the general heading, "grinding." The usual classification of most authorities consists of: breaking or coarse crushing, intermediate or secondary crushing, and fine grinding.

On page 711 the equilibrium values given for the producer gas reaction are those of Clement and Adams. These old values are not accepted by present day physical chemists who are working on the equilibrium of systems involving CO and CO_2. The most generally accepted values are those of the Rhead and Wheeler second series and of Jellinek and Diethelm.

On page 219, in discussing the use of ferric sulphate, no mention is made of the employment of this reagent as a solvent for certain sulphide ores of copper.

A number of errors in proof reading found in the fifth edition were also present in the fourth and have not been corrected, but few of these are serious except one on page 791, where $C + CO_2 = 2CO \pm 38.85$ calories should be — 38.85.

Rogers' "Industrial Chemistry" has long been a reference book in every chemical library. The present edition is even better than former ones and should continue to receive its well-deserved popularity. John D. Sullivan (14)-B-

Steel and Alloys. Robert Hadfield. *Times,* London, Faraday Number, Sept. 21, 1931, page 11.

The author notes that beside all his other physical and chemical works and discoveries, Michael Faraday had done quite extensive and systematic work in metallurgy. In a box were found 79 specimens of steel and alloyed steel which, upon investigation, proved to be alloys of steel with 16 different elements. Among others was one containing 50% Pt; one with 80% Pt; another with 50% of rhodium; others with Ni, Cu, and Cr. It can be said justly that Faraday was also a pioneer in this field of metallurgy. Ha (15)

The Chemical Composition of Prehistoric Bronzes. (Zur chemischen Zusammensetzung der vorhistorischen Bronzen.) John Sebelien. *Chemiker-Zeitung,* Vol. 55, Dec. 19, 1931, pages 973-974.

Analysis was made of 29 objects of Egyptian origin. Up to about 4000 B.C. fairly pure Cu was used. Bronzes are found from about 1200 B.C. on. The objects contained from 57 to 100% Cu, with Fe, Zn, As, Sn, Ag, Bi, Ni and sand as impurities. CEM (15)

Salt Cellars—Old and New. Part 2—Salts from the 18th Century to the Present Time. A. F. Saunders. *Metal Industry,* N. Y., Vol. 30, Feb. 1932, pages 57-58.

Descriptions and illustrations of salt cellars are given. PRK (15)

History of the Wire Industry. K. B. Lewis. *Wire & Wire Products,* Vol. 6, Dec. 1931, pages 465-469, 484-485; Vol. 7, Jan. 1932, pages 9-11, 29.

An historical sketch of wire drawing is given from the crude beginnings in 1000-1400 A.D., when the iron was melted directly from the ore in small charcoal fires and recovered in crude lumps mixed with slag and dirt. The iron was hammered into bars and then drawn. Between 1500 and 1600, speed hammers became available. This was the beginning of the modern industry. Dies are about 100 yrs. old. Coating, enameling and drafting practices are described. There are some interesting old photographs. The historical development of rod production of hammering and slitting mill from about 1600 to the present day is described; future possibilities are discussed. Ha (15)

Platinum as a Factor in the World's History. (Platin als weltgeschichtlicher Faktor). W. Ostwald & E. Brauer. *Siebert Festschrift,* 1931, pages 240-256.

General discussion of oxidation of NH_3 to HNO_3 by a Pt catalyst, with photographs of commercial installations. HWG (15)

Faraday and His Metallurgical Researches. Robert A. Hadfield. Chapman & Hall, London, 1931. Cloth, 6½ x 10 inches, 329 pages. Price 21s.

The first 136 pages are historical, dealing with Faraday and his contemporaries. The next 105 pages describe in great detail the examination of 79 specimens of steel and alloy steel made by Faraday in the Royal Institution in 1819-1824. The steels were melted in crucibles in a bellows-blown, forced-draft coke furnace and allowed to freeze in the crucible. The alloying elements mostly used were of the platinum group, those metals being at that time more readily available than the modern alloying elements. The samples were small. All were found packed in a 9" x 5½" x 5½" box bearing labels in Faraday's writing. Chemical analysis, microscopic examination and a few determinations of magnetic properties, hardness, critical points, behavior under corrosion, etc. were made. Two tests were made on tiny tensile specimens, one of 0.94% C, 0.74% Pt, and one of 0.92% C, 1.20% Rh, forged from Faraday's samples and normalized. (Faraday's steels contained only traces of manganese.) The results indicate a very slight strengthening effect of Pt and Rh over a plain carbon steel of low manganese. Dilatometer curves are shown for these two steels. Critical point curves are shown for steels of 1.06% C, 2.18% Ni, 0.75% Au and 0.94% C, 0.74% Pt. Some samples of steel containing Ag indicate that the solubility of Ag in high carbon steel is low. Faraday had made this statement on the basis of visual examination. The samples of steel with Au are structurally similar to carbon steel and Au up to 0.90% appears to be soluble and not to affect the eutectoid ratio.

Steels of 1.09% C, 0.53% Cr.; 1.59% C, 2.36% Cr; 0.94% C, 0.75% Ni; 0.65% C, 2.19% Ni; 1.30% C, 1.50% Cu; 1.05% C, 2.79% Cu, four with Ag, three with Rh, 17 with Pt and three with Pt and Ag, Au and Ag and Ni and Au were found among. A tiny knife of usable quality was made of the 0.94% C, 0.74% Pt steel, and a small razor from one of 0.94% C, 0.69% Pt. A razor was also examined which was given by Faraday to a friend, which was found to contain 1.10% Pt. These razors would shave, but were not superior in performance. Evidence is submitted indicating that, on the basis of Faraday's tests, a steel containing silver was used commercially for a few years by a firm in Sheffield, which thought the alloy steel to be better than the carbon steel it had been using.

A few other samples of alloys made by Faraday, with as low as 0.07% C and up to nearly 50% Pt or Rh and one with about 23% Pd, were examined. The high Rh alloy appears to have some value as an acid-resistant alloy. The experimental difficulties Faraday had in making alloy steels 110 years ago were very great, and the lack of methods of quantitatively evaluating the properties prevented Faraday from finding out the real effect of the alloying elements used. Although this work of Faraday is the first attempt to make alloy steels on record, it is doubtful if any other experimenter has made up as many Pt and Rh steels.

The balance of the book is made up of comments on later developments on alloy steels, especially those studied by Hadfield or produced by his firm. Although Faraday's name is primarily connected with electricity, he was a pioneer in metallurgy. Sir Robert Hadfield's study of Faraday's samples and his account of Faraday himself are of historical interest, and it is evident that Sir Robert found his task a delightful one. H. W. Gillett (15)-B-

Silver in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 2.

Ag price in 1931 was the lowest on record. World production is estimated at about 196 million ozs. (52 million less than 1930). U. S. production (30,967,618 ozs.) was roughly ½ the average of the past 20 years. Canadian production was 23% less (20,403,771 ozs.). AHE (16)

British Columbia in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 19.

The estimated return from mines in British Columbia in 1931 is $36,000,000 as compared with $55,500,000 in 1930. AHE (16)

Gold, Silver, Copper, Lead and Zinc in Colorado in 1929. Chas. W. Henderson. *Mineral Resources of the United States,* 1929, *United States Bureau of Mines,* Part 1, Oct. 31, 1931, pages 921-968.

The total gross value of Au, Ag, Cu, Pb and Zn recovered in Colorado in 1929 decreased 7% from 1928; Au decreased 17%, Ag 1%, Pb 1%, Zn 11%, while Cu increased 27% in value. Production was Au $4,417,358; Ag 4,397,377 oz., $2,343,802; Cu 8,905,074 lb., $1,567,293; Pb 48,889,906 lb., $3,080,064; and Zn 58,861,000 lb., $3,884,876. AHE (16)

The Basic Bessemer Process: Some Considerations of Its Possibilities in England. Vernon Harbord. *Engineering,* Vol. 131, May 22, 1931, pages 683-684; discussion, May 22, 1931, pages 679-680.

Condensed from paper read before the Iron and Steel Institute, London, May 8, 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 275. LFM (16)

Economies and Efficiencies in Mine and Plant. A. H. Hubbell. *Engineering & Mining Journal,* Vol. 133, Jan. 1932, pages 5-9.

A general review of directions in which savings and improvements may be effected is accompanied by a chart showing the technical interrelation of the metal and non-metal industries through common production and extraction processes and several tables. WHB (16)

The Lead Situation. H. G. Crane (St. Joseph Lead Co.). *Mining Congress Journal,* Vol. 17, Nov. 1931, pages 592-593, 596.

The United States has adhered to high production schedule with natural result of rapidly decreasing market price for lead. The daily world production of lead for each country is shown for the same months in 1929 and 1931, with percent increase or decrease. Graph of total refined lead production from domestic mines and secondary lead production is given in short tons for years 1885 to 1930. The per capita consumption of lead has increased greatly since 1913, 8.75 lbs. per capita, compared with 12.05 lbs. per capita in 1929. With regard to tariff protection, over-production in the U. S. has prevented the domestic lead miner from getting the full benefit of the tariff, as domestic price has been forced to within a short distance of the London price level. Virgin lead situation is complicated by growing importance of secondary or scrap lead. The smelting and refining of secondary lead is now an integral operation of nearly all primary lead producers. DTR (16)

New Method Cuts Cost of Handling Sheet Steel. C. B. Crockett. *Steel,* Vol. 89, Oct. 5, 1931, pages 31-32.

By the installation of a synchronized system using two types of mobile equipment the cost of handling sheets, including method of packing, storage space required, appearance of plant, injury to workmen, etc., was reduced by 85%. Ha (16)

Power Rate Influences Electrical Equipment and Melting Cost. O. H. Henschel. *Foundry,* Vol. 59, June 1, 1931, pages 57-59.

A proper study of the power rates available to the foundry may lead to considerable saving in the energy bill. An example for 3 different rates for the same consumer illustrates the manner in which the whole layout, substation and auxiliary, as well as operation can be influenced by the rate at which energy is purchased. Ha (16)

Establishing a Furnace-Hour Rate for a Brass Casting Shop. Waldo Hutchinson. *Canadian Foundryman,* Vol. 22, Sept. 1931, pages 10-13.

A complete discussion of the methods adopted in establishing a furnace-hour rate for a brass casting shop, in which special methods of casting are dealt with in some detail. OWE (16)

The Situation of German Iron Foundries in 1931. Th. Geilenkirchen. *Foundry Trade Journal,* Vol. 46, Jan. 21, 1932, pages 53-54.

A discussion of the economic situation in Germany during 1931 in so far as it affected the iron foundries of that country. OWE (16)

Economics of the Minnesota Iron Mining Industry. E. W. Davis. *Civil Engineering,* Vol. 1, Dec. 1931, pages 1349-1351.

Data secured from the Tax Commission show that there is in Minnesota sufficient iron ore to last about 35 years. This value is placed on material classed as high-grade ore. In addition to this high-grade ore the state contains immense quantities of low-grade ore not now being used, which pays little or no tax because it has no commercial value. It is estimated that this low-grade if utilized would last for several hundred years. The total tax on ore is about $0.50/ton of ore shipped. Of this, the ad valorem tax amounts to $0.39/ton, and the occupation and royalty taxes together amount to $0.11/ton. The occupation and royalty taxes are paid on tons of ore shipped, and if no ore is shipped no taxes are paid. The ad valorem tax is a property tax and decreases as the value decreases. The mining companies, therefore, mine and ship the ore as rapidly as possible and surrender the lease as soon as the available high-grade ore is gone. The present system of taxation does not, therefore, stimulate the utilization of the low-grade ore. The result is that when the high-grade is exhausted the mining companies turn to foreign countries for their high-grade ore. It has not yet been demonstrated that the low-grade material can be economically converted into merchantable ore. Minnesota should therefore assume a liberal attitude toward the low-grade ore industry and do everything in its power in the very near future to assist the mining companies in demonstrating the commercial value of these low-grade materials. FOUNDRY PRACTICE & APPLIANCES (22)

The Casting of Threads. W. Schäfer. *Foundry Trade Journal,* Vol. 46, Mar. 17, 1932, page 172.
An article translated from *Die Giesserei* and accompanied by 3 diagrams. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 50. OWE (22)

Effect of Heat on the Permeability of Sea Coal Facing Sands and Core Sand Mixtures. Walter M. Saunders & Walter M. Saunders, Jr. *Transactions & Bulletin American Foundrymen's Association,* Vol. 2, Oct. 1931, pages 440-448.
On heating test cores of molding sand and sea coal mixtures, and also core sand with binders, the permeability decreases considerably. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. CHL (22)

Nickel Affects Strength of Bronze Foundry Mixtures. N. B. Pilling & T. E. Kihlgren. *Foundry,* Vol. 59, Nov. 1, 1931, pages 54-58.
Abstract of a paper read before the American Foundrymen's Association in Chicago. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 25. VSP (22)

Deep Etching of Brass Applied to Gating Problems. R. W. Parsons. *Transactions & Bulletin American Foundrymen's Association.* Vol. 3, Feb. 1932, pages 843-856.
Deep etching was applied to determine the best method for gating castings. There is a relationship between length of bar and diameter to obtain sound castings. Pouring temperature was shown to have a definite relation to the physical properties of the castings. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. CHL (22)

The Relationship between the Engineering and the Foundry Trades. L. G. Pomeroy. *Engineering,* Vol. 132, July 3, 1931, page 10.
Abstract of a paper read before the Institute of British Foundrymen, June 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 280. LFM (22)

Bath Tub Molding with Only One Jolter. (Badewannenformerei mit nur einem Rüttler.) U. Lohse. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Jan. 16, 1932, pages 55-56.
The general considerations for quantity production in foundries are discussed and a method of molding bath tubs is described where only one jolter is required; the described plant has automatic equipment for the preparation of the molding sand. Ha (22)

Recent Developments in Cast Iron and Foundry Practice in Great Britain. J. G. Pearce. *Engineering,* Vol. 132, July 3, 1931, pages 9-10.
Abstract of a paper read before the Institute of British Foundrymen, June 1931. See *Metals & Alloys,* Vol. 3, Apr. 1932, page MA 107. LFM (22)

Some Jobbing Foundry Molding Jobs. J. H. List. *Foundry Trade Journal,* Vol. 46, Feb. 4, 1932, page 87.
A description of 3 jobs—(1) an ejector water heater cast in a zinc-free alloy, (2) a small cast-iron vase pedestal, and (3) a small grease trap. The article is accompanied by 2 photographs showing the mold and cores used in the production of the water heater, and 2 diagrams showing the arrangement of the mold for the vase pedestal and grease trap. OWE (22)

The Influence of the Condition of the Wall of the Mold on the Formation and Amount of the Graphite Content in Gray Iron. (Ueber den Einfluss der Formwandbeschaffenheit auf die Ausbildungsform und Menge des Graphitgehalts im Grauguss.) H. Nipper & E. Piwowarsky. *Die Giesserei,* Vol. 19, Jan. 8, 1932, pages 1-3.
Metallographically as well as chemically no difference was found for wall thicknesses of the casting up to 185 mm. The walls of the molds were coated with graphite, coke dust, soot, fire clay and coarse sand. Ha (22)

New Cupola Melting Methods. (Neue Kupolofen-Schmelzverfahren.) R. Stotz. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Jan. 24, 1932, pages 42-44; Feb. 7, 1932, pages 58-59.
The article deals in particular with the production of malleable castings and shows that many improvements can be attained by a careful supervision of the whole melting process. These improvements are shown in decrease fluctuations in composition of the malleable castings, and in more uniform mechanical properties. In comparing the C and Mn contents of malleable castings for the years 1926 and 1931 it is shown that, according to the use of the casting, the C content decreased from 3.6-3.2% to 3.2-2.6% whereas the Mn content increased from about 0.1% to 0.3%-0.5%. The steel scrap content in the charge of the cupola has also been increased. Whereas 10-15% steel scrap was common for malleable casting charges 10 years ago, this amount has been increased now to 20-25%, in some cases even up to 30%. There are no objections to such high contents of scrap in the charge. The loss of metal through oxidation is not higher with increasing amount of scrap. GN (22)

Molding and Casting a 32-ton Foundation Block. G. E. Morgan. *Foundry Trade Journal,* Vol. 46, Jan. 21, 1932, pages 55-56; Feb. 4, 1932, pages 83-85.
An article accompanied by 21 diagrams, in which a description is given of the methods used in the foundry of the East Indian State Railways for molding a 32-ton foundation block for a steam hammer. Attention is given to the raw materials used as well as to the general method of preparing the pit, constructing the mold and pouring the casting. OWE (22)

Sand Testing in the Foundry. Wm. Y. Buchanan. *Foundry Trade Journal,* Vol. 46, Feb. 11, 1932, pages 97-100; Feb. 18, 1932, pages 113-116, 124.
Paper read before the Scottish Branch of the Institute of British Foundrymen, dealing with the standard British Cast Iron Research Association compression strength and permeability apparatus and, in particular, with experiments on the effect of milling on the compression strength and permeability of sand. Some attention is directed to the effect of loading rate upon results of compression tests, and a comparison is made between results obtained with hand-rammed and compression-made cores. The effects of moisture content on the properties of sand are dealt with in some detail, as is also the influence of varying the proportions of new sand to facing sand. The article is accompanied by 4 tables and 29 diagrams. OWE (22)

Electric Furnaces. *Electrician*, Vol. 108, Jan. 22, 1932, page 106; *Foundry Trade Journal*, Vol. 46, Feb. 4, 1932, page 81.

A brief description is given of electric furnaces erected at the works of the Northern Aluminium Co., Ltd., Banbury. They contain 2 of the largest resistance units for heat treatment in England. OWE + WHB (23)

High-Frequency Induction Furnaces. *World Power*, Vol. 27, Feb. 1932, page 118; *Foundry Trade Journal*, Vol. 46, Feb. 11, 1932, page 104.

The Witton 6-cwt. high-frequency induction furnace (Stobie patent) is partially cored. The path of the magnetic field is mainly through thin laminations of high-Si low-C steel, which is brought to a central position inside the induction coil. Instead of a magnetic field weakened by air resistance (as in earlier furnaces) and uncontrolled as regards its distribution within the crucible, the electromagnetic system is so strong and centrally situated in the crucible that it has been possible to make the remainder of the electrical equipment entirely subservient to considerations of safety and efficiency (both electrically and metallurgically). OWE + WAT (23)

Some Electric Furnace Developments in 1931. C. L. Ipsen. *Wire & Wire Products*. Vol. 7, Mar. 1932, pages 78-79.

A condensed description is given of improvements in electric furnaces for annealing coil strip, sheet annealing and for Cu brazing as developed by the General Electric Co. Ha (23)

Modern Developments in Pulverized Coal Firing. R. Jackson (Alfred Herbert, Ltd.). *Transactions Tokyo Sectional Meeting, World Power Conference*, 1929, Vol. 3, 1931, pages 747-770.

A general description, including metallurgical furnaces. AHE (23)

Pulverized Fuel: Its Application to the Metallurgical Industries. R. Jackson. *Metal Industry*, London, Vol. 39, Dec. 25, 1931, pages 605-608.

From a paper read before The Co-Ordinated Societies, Birmingham, Dec. 10, 1931. The advantages and costs of pulverized fuel for Cu and Sn smelting are given. PRK (23)

A Study of the Carbonization Temperature of Coal and the Time Required. Taizo Kuroda & Kojiro Takei. *Fuel in Science & Practice*, Vol. 11, Feb. 1932, pages 56-60; *Proceedings World Engineering Congress, Tokyo*, 1929, Vol. 32, 1931, pages 207-221.

Higher carbonization temperature does not always produce the harder coke. The relation between the temperature of carbonization and the time required must be ascertained and correlated with the quality of the resulting coke. DTR (23)

Dimensions, Load, Regulation and Consumption of Electrodes in Electric Arc Furnaces for Melting of Gray Iron and Steel (Ausmasse, Belastung, Regelung und Verbrauch der Elektroden der Lichtbogenöfen zum Schmelzen von Grauguss und Stahl). E. Kothny. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 13, 1931, pages 873-879.

A complete tabulation of the distribution of furnaces with electric arc in different countries is given and all the above-mentioned details are compiled. Ha (23)

The Behavior of Solid Fuels During Oxidation. Burrows Moore. *Fuel*, Vol. 10, July 1931, pages 293-296, Aug. 1931, pages 344-349; Sept. 1931, pages 394-400.

Part V. Increasing the O temperature (1) causes increased rate of combustion and heat evolution during the pre-ignition period, which rate in the case of cokes decreased soon after ignition and remained practically uniform for a considerable period during which the rate of heat produced by the oxidizing fuel was nearly equal to the rate of heat loss from the fuel; (2) does not increase the mean or maximum temperature attained by the combustion; (3) tends to ensure more complete combustion in the case of fuel charges which are not widely dispersed as fine particles in the O or air used for combustion; (4) does not affect greatly the rate of heat loss from the fuel during the combustion and, therefore, the considerable difference between O temperatures which may exist when the ignition and combustion characteristics of fuels with considerably different glow-point temperatures are compared do not introduce serious errors in estimates of ignition factors and combustible capacities by the method employed; (5) does not greatly increase the combustible capacity of the fuel. There is no advantage, in processes using powdered fuel for firing purposes, in increasing the O or air temperature above the ignition temperature. Part VI. Exposure of bituminous coal for several hours at normal atmospheric temperature and at a pressure of 650 mm. of Hg to air containing a high proportion of (a) O and (b) N causes no marked change in the ignition and combustion characteristics of the coal. Similar exposure to air containing a high proportion of CO_2 leads to increased reactivity of the coal to O; the apparent increase of reactivity probably is related to the displacement by the CO_2 of occluded gases from the fuel. The absorption by coal, at normal temperature and pressures less than 650 mm. of Hg, of O and N appears to be chiefly of a physical nature. Normal "constitutional" moisture is not objectionable in connection with the ignition and combustion properties of coal but moisture considerably in excess of the normal content raises the relative ignition temperature, reduces the combustible capacity and decreases temporarily the tendency for spontaneous ignition to occur. Part VII. The spontaneous ignition tendencies of coals have been investigated by the relation between (1) the O temperature, and (2) the time of the occurrence of (a) glowing of the coal and (b) ignition of the volatile matter and by the comparison of the ignition factors of the coals. Results indicated that the tendencies for ignition of the volatile matter to occur were greatest with coals from seams associated with fires in the mine, and the highest ignition factors were obtained from these coals. The results provide evidence that the method could be employed to assist in identifying seams or parts of seams particularly liable to spontaneous ignition, and to differentiate coals according to their tendencies to spontaneous ignition. WAT (23)

Linear Expansion of Common and Black Silica Bricks on Heating. P. P. Budnikoff & V. Mueller. *Domez* (Achievements of Metallurgy in USSR and Abroad), No. 10, 1931, pages 24-28; *Berichte der deutschen keramischen Gesellschaft*, Vol. 13, Jan. 1932, pages 28-31.

Black grade of silica brick was made by adding to the mix some blast furnace dust until the finished brick contained about 5% of Fe_2O_3. The expansion of common (94.72 SiO_2, 1.91 Fe_2O_3, 2.29 CaO) and black (91.08 SiO_2, 5.26 Fe_2O_3, 2.37 CaO) silica brick was almost the same to 900° C. Closer study of the expansion curves shows that trydimite content is higher in common bricks than in black and that the latter retains a larger amount of the original quartz. Quartz transformation is somewhat slower in black brick which is about 30% stronger. GN (24)

Zirconium Oxide, Its Production and Utilization. (Ueber das Zirkonoxyd, seine Herstellung und Verwendung.) H. Trapp. *Die Metallbörse*, Vol. 21, Aug. 12, 1931, pages 1516-1517; Aug. 19, 1931, page 1565.

Reviews the properties of zirconium oxide, its commercial application and natural occurrence. The largest part of the paper pertains to a detailed outline of the various chemical methods of preparing ZrO_2. EF (24)

Investigations into the Scorification of Refractory Materials. V. The Relation of Flux Content and Porosity to the Scorification of Fire Brick. (Untersuchungen über die Verschlackung feuerfester Stoffe. V. Der Einfluss von Flussmitteln und Porosität auf die Verschlackung feuerfester Stoffe.) H. Salmang & O. Heberstreit (Technische Hochschule Aachen). *Feuerfest-Ofenbau*, Vol. 8, Jan. 1931, pages 1-8.

Scorification tests on mixtures of 1 Al_2O_3 and 2 SiO_2 in a highly pure state and with low additions of fluxes, mainly Fe_2O_3, CaO, TiO_2, Na_2O, molded into cupels are reported. Due to the great porosity of the cupels, no differences were noticed regarding the depth of penetration of 8 different synthetic slags regardless of the flux. Another set of experiments refers to crucibles of burnt and unburnt kaolin (Zettlitz) containing various amounts of fluxes. TiO_2, Fe_2O_3 and CaO led to the most pronounced scorification if they are present exclusively in either the slag or crucible material. If the fluxes are present in both slag and crucible, the samples are less corroded. The low corroding rate of Na_2O is stressed. In a further set of experiments, blast furnace slag rich in CaO and open hearth slag rich in FeO were employed. The scorification did not prove to be proportional to the porosity of the 36 refractories tested. Only in case of the very same testing material, the slag attack increases with rising degrees of porosity. The micro-structure of refractories is of importance as to whether or not the individual pores are separated from each other or connected by minute capillaries. Hence refractories of the same chemical composition and porosity may exhibit different rates of scorification. EF (24)

Investigations into the Scorification of Refractory Materials. VI. Investigation of the Corroding Power and Constitution of Slags of Non-Ferrous Plants. (Untersuchungen über die Verschlackung feuerfester Stoffe. VI. Untersuchungen über die Korrosionskraft und die Konstitution der Metallhüttenschlacken.) H. Salmang & J. Kaltenback (Technische Hochschule Aachen). *Feuerfest-Ofenbau*, Vol. 8, Nov. 1931, pages 161-169.

12 references. The corrosive ability of the following oxides: FeO, Cu_2O, SnO, NiO, Fe_2O_3, Ni_2O_3, PbO, ZnO, CaO, BaO, Al_2O_3, SnO_2, Sb_2O_5, SiO_2, Cr_2O_3 and of $BaSO_4$, FeS and synthetic binary, ternary and quarternary silicate slags were quantitatively determined with respect to their scorification of refractory crucibles of the following analysis: 59.15% SiO_2, 37.55% Al_2O_3 and 2.4% Fe_2O_3. The experiments were carried out at 1320, 1410 and 1500° C. The original paper must be consulted for the wealth of data which are clearly presented in 19 illustrations. EF (24)

Furnace Walls. Part II. George P. Reintjes. *Blast Furnace & Steel Plant*, Vol. 19, Nov. 1931, page 1494.

By placing 2 interlocking tile at the angles of the furnace walls, it has been found unnecessary to maintain a mason at each corner of the walls, working on the "lead." Production per mason is increased and the strength of the furnace structure is improved. Cost of labor on the average furnace lining has been reduced about 25%. MS (24)

Advances in the Fields of Refractory Materials. (Neuere Fortschritte auf dem Gebiet hochfeuerfester Stoffe.) H. Trapp. *Die Metallbörse*, Vol. 21, Nov. 11, 1931, pages 1977-1978; Nov. 18, 1931, pages 2009-2010; Nov. 25, 1931, pages 2041-2042; Dec. 2, 1931, pages 2073-2074.

Differs between physical melting point of refractory materials and service temperature at which they can still advantageously be used. The avoidance of low melting compounds, eutectics, etc., due to the attack of metals, oxides, slags, ashes, etc., is discussed. The physical properties at elevated temperatures which are of decisive influence on the value of refractory materials and the determination of those physicals are taken up. The different materials on the market are critically discussed separately mainly referring to refractories on Al_2O_3, SiO_2, MgO and ZrO_2 base. EF (24)

Melting Diagrams of Highly Refractory Oxides III. (Schmelzdiagramme hochstfeuerfester Oxyde. III.) H. Von Wartenberg & W. Gurr. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 196, No. 4, 1931, pages 374-383.

The following melting temperatures have been determined: Fe_2O_3 (with impurities of Fe_3O_4) 1570° C., Mn_3O_4 1705°, ZnO 1810°, is very volatile, CeO_2 above 2600° C., NiO at 2090, CoO at 1935°, TiO_2 at 1850°, SnO_2 begins to evaporate rapidly at 1700°, SiO_2 can be evaporated easily above 1800° from $ZrSiO_2$. All diagrams are reproduced. Ha (24)

Special Refractories. *Metallurgist*, Sept. 1931, pages 136-138.

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

The Influence of Some Contaminations on Refined Lead. (Einfluss einiger Verunreinigungen auf Raffinadeblei.) Thews. *Die Metallbörse,* Vol. 21, Aug. 8, 1931, pages 1492-1493.

Critically discusses an analysis of Pb for pipe material, suggested by the British Non-Ferrous Metals Research Association, running as follows: 98.25% Pb, 1.5% Zn, 0.25% Cd. The harmful effect of Sb, Bi, Cu, As, Ag, Zn, Cd, Sn, Na and Al is considered and the author urges the use of the purest refined Pb for material exposed to corrosion attacks. EF (27)

The Effect of Various Elements on the Quasi-Isotropic State and the Sensitiveness to Section Thickness of Cast Iron. *Foundry Trade Journal,* Vol. 46, Mar. 3, 1932, pages 147, 152.

An extended abstract of an article by Piwowarsky & Söhnchen, which appeared in *Die Giesserei* (Vol. 18, 1931, pages 533, 537). The article is accompanied by 5 diagrams. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 25. OWE (27)

Quality of Rails at Kertch Works. M. N. Karnaev. *Domez,* (Achievements of Metallurgy in USSR and Abroad), No. 10, 1931, pages 29-37. (In Russian).

Testing covered 378 heats of basic Bessemer rail steel for physical properties and the influence of As content. Analysis varied between 0.30 and 0.60 C while Mn was between 0.60 and 1.70. Impact tests were made on the rails and they were classified on the basis of rolling defects. 28.8 primes, 42.8 seconds and 28.4 scrap were obtained on the whole lot. Physical testing of 23 rails containing 0.14-0.175 As did not demonstrate the deteriorating effect of its content. (27)

Carbon and Iron. (Kohlenstoff und Eisen.) F. Rosendahl. *Die Metallbörse,* Vol. 21, May 23, 1931, pages 963-964; May 30, 1931, pages 1011-1012; June 6, 1931, pages 1059-1060.

The historical development of the Fe-C constitutional diagram, the different constituents therein and the phenomena occurring in plain carbon steels are reviewed. EF (27)

Manganese and Sulphur in Forging Steels. Archibald Allison. *Metallurgia,* Vol. 5, Mar. 1932, pages 171-172.

Discusses distribution and effects of S in rimmed and killed steels. Concludes that S is not to be too easily blamed for forging failures. JLG (27)

Nickel Alloy Cast Iron for the Automobile Industry. (Nickellegiertes Gusseisen im Kraftwagenbau.) H. Kalpers. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Feb. 7, 1932, page 60.

Ni in cast iron improves its structure, the hardness, tensile strength, machinability, and the resistivity against heat and corrosion; Ni castings are denser. Due to the better mechanical properties the weights of Ni castings can be lower than those of castings without Ni. GN (27)

Zirconium Alloys For Steel Production. (Zirkonlegierungen bei der Stahlherstellung.) *Bergwerk und Hütte,* Vol. 29, Feb. 5, 1932, pages 16-17.

General discussion as to how Zr affects the physical properties of steel. GN (27)

The Effect of Molybdenum on Medium-Carbon Steels Containing 1 per cent. to 2.5 per cent. of Manganese. G. Burns. *Engineering,* Vol. 132, Oct. 2, 1931, pages 443, 447-448.

Includes discussion. Condensed from paper read before the Iron & Steel Institute, Swansea, Sept. 29, 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 323. LFM(27)

Influence of Copper on the Acid Solubility of Low Carbon Ingot Steel. (Untersuchungen über den Einfluss des Kupfers auf die Säurelöslichkeit von kohlenstoffarmen Flussstahl.) Peter Bardenheuer & Gustav Thanheiser. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 14, Report No. 196, 1932, pages 1-9.

Distinction is made between rate of solution in acids and weather resistance of material. After a thorough review of the literature, tests were made of the effect of Cu additions on solubility of low C steels, with varying P and S content, in N/5 solutions of H_2SO_4, HCl, HNO_3, and 2% citric acid. Time of solution attack 24 to 288 hrs. Cu additions were from 0.07 to 0.33% with Thomas steels. Cu additions for steels, with increasing amounts of P and S, were 0.01 to 0.70%. Cu additions to high P or S steels very strongly decreases rate of solution in H_2SO_4, HCl or citric acid. Cu scarcely affects solution rate of low P and low S steels, and with pure steel samples, Cu may even cause a higher rate of attack by acids. Solubility in HNO_3 is independent of Cu. Presence of $CuSO_4$ in solvent acid generally accelerates rate of solution, and the more insoluble steels are affected the most by the presence of $CuSO_4$ in the acid. Includes 22 references, 15 illustrations and 7 tables. DTR (27)

Constitution, Spontaneous Graphitization and Thermal Hysteresis of Titanium Cast Iron of Low Total Carbon Content. (Constitution, graphitisation spontanée et hystérésis thermique des fontes à bas carbone total). Jean Challonsonnet, *Comptes Rendus,* Vol. 194, Jan. 18, 1932, pages 283-285; *Journal du Four Electrique,* Vol. 41, Apr. 1932, page 142.

The author has prepared a series of Ti alloys of low C content, using Fe containing 2.3% total C, 0.9% Si, 0.3% Mn, 0.06% S, and 0.01% P as a base, and ferro-titanium containing 27% Ti as an addition agent. The materials used gave ingots 20 mm. in diameter and 200 mm. long, and rods 6 mm. in diameter and 100 mm. long. The latter were used for dilatation experiments. The article is accompanied by a table in which are quoted Brinell hardness numbers, the Curie points of the cementite, the temperatures of transformation, and the temperatures of spontaneous graphitization of a series of 9 irons containing from 0 to 1.93% Ti. The hardness of the alloys decreased as the Ti content increased up to 1.30% and then increased again. The author remarks that Ti behaves in its effect upon cast Fe very similarly to Si, modifying the various characteristics of the basic material in much the same way. The article is illustrated by one diagram. JDG + OWE (27)

The Influence of Silicon on Nickel Steel. R. Harrison. *Engineering,* Vol. 132, Oct. 2, 1931, pages 443-444, 450-452.

Includes discussion. Condensed from paper read before the Iron & Steel Institute, Swansea, Sept. 29, 1931. See *Metals & Alloys,* Vol. 1, Dec. 1931, page 323. LFM (27)

Notes on Bismuth Bearing Copper. (Bemerkungen über wismuthaltiges Kupfer.) C. Frick (Bergakademie Clausthal). *Die Metallbörse,* Vol. 21, July 29, 1931, pages 1395-1396.

The properties of Bi with special reference to its behavior in metallurgical refining processes are discussed. Tensile tests, conductivity measurements and rolling experiments were carried out with Cu containing additions of Bi up to 2%. Bi materially impairs the physicals: tensile strength drops 60% due to the addition of 2% Bi and the electrical conductivity decreases about 30% owing to contents of only 0.1% Bi. The maximum amount of Bi allowed to be present during hot rolling is 0.01% and 0.05% for cold rolling. Micro-structural examination disclosed that less than 0.05% Bi is in solid solution. At low concentrations Bi is encountered only at the grain boundaries. On solidification pure Cu crystals are segregating first and at essentially lower temperatures Bi solidifies. On heating internal stresses occur which might even result in disintegration of the contaminated Cu. EF (27)

Effect of Vanadium in High-Speed Steel. A. B. Kinzel & C. O. Burgess. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 468, Feb. 1932, 9 pages; *Iron Age,* Vol. 129, Feb. 25, 1932, pages 488-490.

The effect of increasing quantities of V on the hardness and cutting properties of steel containing 18% W and 4% Cr was studied. With 0.65 to 0.75% C the hardness of the heat treated steel decreased when the V content exceeded 2.5%. If the C was increased, however, the hardness failed to decrease, and lathe cutting tests proved that these high-C, high-V steels had a longer cutting life than the standard 18 W, 4 Cr, 1 V steel. The C should be increased about 0.2% for each 1% increase in V. A 1.5 C, 18 W, 4 Cr, 5 V steel forged well and had excellent cutting properties. Increased V with increased C in Co high-speed steels also improved the cutting properties. VSP + JLG (27)

Hardenable Nickel. (Härtbares Nickel). W. Kroll. *Metallwirtschaft,* Vol. 11, Jan. 15, 1932, pages 31-32.

Contains 2 references. Ni-C-Mg alloys were prepared containing from 0.07 to 0.90% C and 0 to 1.1% Mg. When quenched at 1100° C. and drawn for 24 hours at 500° C. a maximum Brinell hardness of 450 is obtained in the 0.6% C, 0.8% Mg alloy. The best alloys for working contain 0.5-0.6% Mg and 0.1-0.2% C and have a Brinell hardness of 270-370. These alloys have a tensile strength of 122-129 kg./mm.^{2} and 3.3% elongation. Monel metal can also be hardened by C and Mg additions, although to a lesser extent. Ca and Li have a similar effect to Mg, but on a smaller scale. A large number of other elements were alloyed with Ni, but no others were found to have the same effect as C and Mg. The structure of quenched Ni-C-Mg alloys is similar to low C steel. If quenched above 1200° C. the grains become very large. The alloys can be rolled at 1050° C. down to 800° C. In melting deoxidation with Mn is necessary and the ingots should be forged to break up the grain before rolling. The corrosion resisting properties are as good and in some cases better than V2A and 13% Cr steel. CEM (27)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

The Scaling and Corrosion of Steel for Steam Boilers and Superheaters. *Quarterly of the British Electrical and Allied Industries Research Association*, June 11, 1931, J/E/T 20, pages 10-14.

An investigation by Munzinger (A. E. G. *Mitteilungen*, Jan. 1930 *Das Kraftwerk*, page 26) on the cause of the failure of superheater tubes in a certain plant leads to certain fundamental considerations of the design and construction of superheaters. As a result of the investigation it is concluded that the heating surface of the superheater in question was too large and in consequence excessive steam and tube temperatures were attained. Deposits of salts in the tubes by checking the flow of steam probably magnified these temperatures. A strong reaction between the steam and steel tube was created. Although the outside of the tubes was overheated, there was much more corrosion on the inner walls. It is probable that the inner corrosion was accelerated by impurities carried over with the steam, and by free O in the feed water. It is possible also that the steam velocity was too low and thus all the tubes were not uniformly affected, some being insufficiently cooled by the flow of steam. The highest permissible temperature at the superheater exit for the normal operation of superheaters constructed of mild steel is given as 450° C. The determination of the rate of corrosion of the steel by means of the increase of the electrical resistance of a fine wire is an interesting confirmation of a similar method which has already been adopted at the National Physical Laboratory. The value of this research is increased when supplemented by the work of Fellows (*Power*, 1929, page 258). The conclusions drawn by Fellows are: (1) The rate of decomposition of metal increases as the temperature over which the steam passes is raised. (2) The rate of decomposition of the metal decreases as the thickness of the oxide formed on the surface increases. There is no evidence that this oxide attains sufficient thickness or imperviousness to protect completely the metal from further oxidation. WAT (29)

Properties of the Rare Metals for High-Temperature Service. W. H. Swanger (Bureau of Standards) *Symposium on Effect of Temperature on Metals, A.S.T.M.—A.S.M.E. Joint Research Committee*, 1931, pages 610-630.

For abstract of paper see *Metals & Alloys*, Vol. 2, Sept. 1931, page 193. In the discussion the statement is made that Ag is widely used for electrical contacts to the extent of a half million ounces annually, and is by no means confined to low-current, low-pressure service. Pure Ag is generally used but in certain cases small amounts of the Pt group metals are added. Ag alloys containing from 10-15% Cu are sometimes used for contacts. Alloys of Cu are, however, subject to oxidation. Pt, and particularly the Pt-Ir alloys containing 15-25% Ir are standard materials for high-duty contacts. Alloys of Ag and Pd, containing about 60% Pd are also coming into contact service. W is widely used in battery ignition systems in automobiles. The Pt versus 10% Rh-Pt thermocouple is the standard material for temperature measuring operations in the range 1100° to 1500° C. Thermocouples composed of Ir-Rh and Ir-Ru elements have been constructed and have been operated to temperatures up to about 2000° C. Recently an alloy containing 95% Pt with 5% Ni has been found particularly suitable for vacuum tube amplifier filaments. The life of such filaments is reported to be more than 25,000 hours. Pt and particularly the 10% Rh-Pt alloy is widely used for the catalytic oxidation of ammonia-air mixtures to produce nitric acid. Handy & Harman present short-time test data in graphical form for sterling Ag, coin Ag and fine Ag to 1200° F. Experiments on the volatilization of the platinum metals in different atmospheres and under varied conditions are in progress in the laboratories of Baker & Company, Inc. At present the results indicate that all the Pt metals volatilize in air or O_2 as oxide, with the exception of Pd, which loses weight by direct volatilization; that Pt and Rh lose weight very slightly in vacuo or in N_2 or H_2; but that the loss of Pd in vacuo is quite considerable. In contradiction to published data it seems that Rh loses more weight than Pd at 1300° C. WAT (29)

The Thermal Conductivity of Cast Iron between 0 and 100° C. H. Thyssen, Jean R. Marechal & Paul Lenaerts. *Engineering*, Vol. 132, July 3, 1931, page 10.

Abstract of a paper read before the Institute of British Foundrymen, June 1931. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 283. LFM (29)

Creep of Metals. *Metallurgia*, Vol. 5, Mar. 1932, pages 155-156.

Describes the short-time method devised by Barr and Bardgett for determining creep limit. The samples are attached to a weigh bar, and as the material under test elongates the load decreases. For a given temperature there is a straight-line relationship between elongation during a given time and load. By obtaining creep values for 48-hr. tests with several loads, plotting these values and extrapolating to zero elongation, creep limits can be obtained. The test therefore requires only 2 or 3 48-hr. tests. JLG (29)

Some Considerations and Tests for Cast Materials for High-Temperature, High-Pressure Service. L. W. Spring. *Engineering*, Vol. 132, July 3, 1931, page 10.

Abstract of a paper read before the Institute of British Foundrymen, June 1931. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 26. LFM (29)

Some Thermal Properties of Tantalum. C. L. Utterback & L. A. Sanderman. *Physical Review*, Vol. 39, Mar. 1932, pages 1008-1011.

Measurements have been made on the total radiation from very pure, well seasoned Ta from 1000°-2220° K. A spectral temperature scale, $\lambda = 0.667\mu$, is given up to 2100° K. The variation of the resistance of Ta has been measured up to 2600° K. and the thermoelectric power of Ta with pure Pt has been measured up to 692° K. WAT (29)

Effect of Small Percentages of Certain Metals upon the Compressibility of Lead at an Elevated Temperature. Lyall Zickrick (General Electric Co.). *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 14 pages.

Tested various grades of commercial Pb and Pb alloys by making compression test on specimens 0.75"x0.75" in cross section and 1.50" high at a temperature of 200° C. The tests indicated that different leads required different extrusion pressures. The softest were those of highest purity. Small amounts of Cu and Bi increased strength. A Southeastern Missouri Pb, not desilverized, required a greater pressure for a given deformation than a desilverized Bi lead. Sn and Sb increased the resistance to deformation of a high-purity or a Cu-bearing Pb to about the same value. A small amount of Ca apparently increases the deformation pressure. Tests from 160 to 240° C. were made on one brand of Pb. JLG (29)

Bearing Metals at Ordinary and Elevated Temperatures. (Lagermetalle bei normalen und höheren Temperaturen.) Thews. *Die Metallbörse*, Vol. 21, July 18, 1931, pages 1348-1349; Aug. 22, 1931, pages 1589-1590.

In the first part of this publication, bearing metals of Pb and Sn base are considered and the properties at room and elevated temperatures of some 16 representative analyses are tabulated. The balance of the paper confines itself to Cu bearing alloys and compiles in 3 tables interesting data on composition, tensile strength, elongation, proportional and elasticity limit, and Brinell Hardness at 21°, 150° and 310° C. EF (29)

High Pressures and High Temperatures for Steam Prime Movers. O. A. Wiberg. *Transactions Tokyo Sectional Meeting, World Power Conference*, 1929, Vol. 3, 1931, pages 1129-1146; *Engineering*, Vol. 133, Jan. 1, 1932, pages 27-28.

The object of this paper is to illustrate the possibilities of utilizing the advantages of high pressures and temperatures in power plant design. The analysis is based upon a series of tests of materials at elevated temperatures. It is shown that under certain assumptions as to limiting stresses, one group of materials, representing the C steels, gives a maximum thermal efficiency for a certain combination of temperature and pressure, while another group, representing the austenitic materials, gives increasing thermal efficiency for increasing temperature and decreasing pressure in a temperature range that can be considered as practical at the present time. The limitations due to the wetness of the discharge steam are shown to modify the results for the first group of materials in such a manner that the optimum combination of pressure and temperature is displaced towards a slightly lower thermal efficiency unless resuperheating is employed. The properties of the materials which are considered of the greatest importance in this connection are the fatigue limit for pulsating stress for lower temperatures and the creep limit for higher temperatures. Ultimate strength, fatigue, yield point and creep limit values for C and austenitic steels are compared graphically between room temperature and 700° C. The magnitude of the permanent deformation at the creep limit is considered. It restricts the applications of stresses to even less than 50% of creep limit for accurate machine parts. LFM + WAT (29)

Measurements by Means of Liquid Helium, XI. Resistance of Pure Metals at Low Temperatures. (Messungen mit Hilfe von flüssigem Helium XI. Widerstand der reinen Metalle in tiefen Temperaturen.) W. Meissner & B. Voigt. *Annalen der Physik*, Series 5, Vol. 7, 1930, No. 7, pages 761-797; No. 8, pages 892-936.

Almost all metals were tested between 1.2 and 273° absolute and the resistances given. The tests lead to the conclusion that the metals Hg, In, Tl, Th, Sn, Pb, Ta and Ti, and eventually Ru and Cb, become supra-conductive; Rb, Zr, V, As and Sb show a tendency to supra-conductivity and should, therefore, be investigated further below 1.2° C. absolute. Tables of characteristic temperatures listed according to the periodic system are given. Ha (29)

Atomic Heats of Ru, Rh and Pd, and the Coefficients of Expansion of Rh and Pd at High Temperatures. (Untersuchungen über den Verlauf der Atomwärmen von Ruthenium, Rhodium und Palladium sowie der Ausdehnungskoeffizienten von Rhodium und Palladium bei höheren Temperaturen.) H. Holzmann. *Siebert Festschrift*, 1931, pages 149-172.

The expansion of Rh is given by the equation

$$l_t = l_{20}\,[1 + 7.628 \times 10^{-6}\,(t - 20) + 0.002268 \times 10^{-6}\,(t - 20)^2]$$

for Pd, by

$$l_t = l_{20}[\,+ 10.637 \times 10^{-6}\,(t - 20) + 0.004594 \times 10^{-6}\,(t - 20)^2 - 0.001521 \times 10^{-9}\,(t - 20)^2].$$

Experiments were run to 1000° C. Atomic heat at constant pressure for Ru is $5.8415 + 0.0019242t$; for Pd, $6.2312 + 0.0016915t$; for Rh, $6.2221 + 0.0018834t$. Constant volume figures are also given. HWG (29)

The Temperature Dependency of the Specific Heat of the Elements of the Eighth Group of the Periodic System. (Ueber die Temperaturabhängigkeit der spezifischen Wärme bei den Elementen der achten gruppe des periodischen Systems.) F. M. Jaeger. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 203, Dec. 30, 1931, pages 97-103.

The equations expressing the exact behavior of the specific heat between 0 and 1650° C. as determined in the last years in the laboratory of inorganic and physical chemistry of the University of Groningen (Holland) are given for Pt, Os, Ir, Ru, Rh, Pa, Fe, Co and Ni. Ha (29)

Annealing Equipment at Franz Seiffert & Co. A. G. (Glüheinsichtungen bei der Firma Franz Seiffert & Co. A. G. Eberswalde.) R. Haspel. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Jan. 24, 1931, pages 112-113.

The difficulties encountered in parts subjected to high temperatures and high pressures are pointed out, particularly that with great variations in these conditions the aging in actual service is accelerated and the life of the part reduced. Careful heat treatment after the finishing process restores the texture of the material so that even at high pressure and temperature combined the aging can be reduced to a minimum. Large furnaces are described in which a whole assembled boiler can be annealed at 910° C.; they are heated by illuminating gas. Ha (29)

Construction and Charging of Ordinary Top Seals in German Blast Furnaces. (Bauart und Schüttung der auf deutschen Hochofenwerken gebräuchlichen Gichtverschlüsse.) Paul Reichardt. *Stahl und Eisen*, Vol. 52, Feb. 18, 1932, pages 157-165.

Report 125 of Blast Furnace Committee of Verein deutscher Eisenhüttenleute. Various types of blast furnace top construction, representative of those in practical use in 147 German blast furnaces, relations between various types of construction, measurement of furnace top seals and pouring of charge are described. DTR (31)

The Bunker Hill Smelter. A. F. Beasley, P. C. Fedderson, J. B. Schuettenhelm & J. W. Johnson (Bunker Hill & Sullivan Mining & Concentrating Co.) *Mining Congress Journal*, Vol. 17, Nov. 1931, pages 618-623, 632.

A thorough plant description of smelting, roasting, blast furnace treatment, Pb refinery and Cottrell plant is given. The S in the sinter for the blast furnaces must not exceed 2%. Therefore all of the sulphide ores and concentrates are pre-roasted in 5 D. & L. machines followed by crushing to 3/4" and final roasting in 5 more D. & L's. There are 4 blast furnaces, 48" × 180" at the tuyeres, and 20'9" deep from the feed floor to the tuyeres. The crucible is 2'3" deep with 2 tuyeres of water jackets forming the sides and ends of the blast furnace. Each furnace requires 5000-6000 ft.^{3} air/min.; average blast pressure is 25 oz./in.^{2}. Exclusive of coke each furnace consumes about 350 tons of charge/24 hrs. Coke added is from 10 to 11% of the charge, which is roughly 52% Pb. *Lead Refinery*: 6 100-ton drossing kettles are used. After the heavy dross has been removed, the bullion is pumped into a clean kettle. A 2" skim is made after blowing. This process of drossing and blowing lowers the Cu content from 0.90% to 0.04%. This dross approximated 9.5% of total bullion for 1930. *Softening*: The Pb is heated to 900° F. and pumped into 1 of 2 350-ton softeners. Softening time depends upon Sb and As. Bullion of average 1.5% Sb and 0.20% As can be softened in 15 to 20 hrs. with a furnace heat of 1600 to 1800° F. The As and Sb form a crust and are skimmed off. *Desilvering*: After cooling to 1000° F., Zn is added in excess of that which is necessary to remove the Au, the Au crust is skimmed off, and the remainder of the Ag is removed by adding additional Zn. The desilverized Pb containing 0.50 to 0.60% Zn and 0.10% Sb is heated to 750° F. and pumped to one of 2 250-ton refiners. Refining temperature is 1300° to 1800° F. The first blow starts at 1200° F. and lasts for 2 to 3 hrs., depending on the impurities and the temperature. At the end of the first blow, 98% Zn and 50% Sb have been oxidized and skimmed. A second blow is made which brings Sb down to 0.0030% and Zn to 0.0015%. The average time for refining a charge is 11 hrs. *Casting*: Refined Pb is allowed to cool to 900° F., tapped, pumped at 700° F. to a casting wheel having 150 molds, cast into 100-lb. pigs and loaded for shipment. Refined Pb produced is 4.2 tons/day/man employed in the Pb and Ag refineries. The Cu dross is treated in a 75-ton reverberatory furnace handling 63 tons/day, with 1% SiO_2 and 1% CaO rock. The Sb skim is treated in a by-product furnace with 3.5% coke and 3.5% galena. Coal used/ton of refined Pb produced, including complete refining of Pb, Au and Ag is 190 lbs.; oil/ton is 4.6 gals. The recovery of Pb, Au and Ag is described in detail. Cottrell Plant: The fume from the D. & L. sintering machines is treated in a Cottrell plant of 120,000 c.f.m. maximum gas volume. Temperature of gases at Cottrell inlet 100° to 125° F., and relative humidity at outlet of treater 50 to 60%. *Bag House*: The fume from the blast furnace, Pb refinery and Ag refinery is treated in a bag house. The refineries produce 40,000 ft.^{3}/min. of gas at 325° F., and the blast furnace 100,000 ft.^{3}/min. at 260° F. The temperature at the bag house inlet is kept below 200° F. 750 tons of fume are recovered/mo. on a 2 blast furnace basis. A McMichael automatic sampler, at an elevation of 75 ft. in the stack, shows an average Pb loss in the stack gas of 350 lbs./day. DTR (31)

The Sintering of Minette Blast Furnace Dust and Fine Ore. (Die Sinterung von Minette-Gichtstaub und -Feinerz.) R. Baake. *Stahl und Eisen*, Vol. 51, Oct. 15, 1931, pages 1277-1283; Oct. 22, 1931, pages 1314-1319.

Report 122 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute, abstract of the author's doctor's thesis before the Clausthal Mining Academy. Includes discussion. Minette furnace dust and fine ore are suitable for sintering. Blast furnace dust with a grain size of about 0.05-0.5 mm. has minimum permeability. However, dusts of a smaller or a larger grain size can be sintered by the Dwight-Lloyd method without difficulty when moistened. The effect of water content, grain size, height of piling and porosity of the material upon the permeability was studied. In order to improve the permeability the following measures are necessary; careful supervision of the H_2O content of the dust or ore which is going to be sintered, very loose piling upon the sintering apparatus and avoidance of shocks of any kind during sintering. The results of preliminary sintering tests check with the actual results of a Dwight-Lloyd sintering plant. The following table indicates the favorable effect of the use of sinter upon the operation of a blast furnace.

Month	% sinter in burden	scrap in burden in % of pig iron	share of crushed minette in burden in % of total minette	% output of burden	production of pig iron per blast furnace in 24 hrs.	consumption of coke in % pig iron production[1]	deposit of dust[2] in % pig iron	deposit of dust[2] in % burden	Remarks
Dec. 1926	....	11.8	61.7	31.7	184 tons	111.3			
Jan. 1927	....	11.8	67.6	31.5	177 tons	113.0	about 35	about 11	fine ore not sifted
Feb. 1927	....	9.8	62.7	31.6	186 tons	109.2			
Nov. 1930	53.2	4.2	100.0	38.2	268 tons	87.5	5.5	2.05	fine ore sifted and sintered with Furnace dust.

Induced Draft Sintering of Iron Ores. (Untersuchungen über die Saugzugsinterung von Eisenerzen.) Walter Luyken & Ludwig Kraeber. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung*, Vol. 13, Report No. 192, 1931, pages 247-260.

Hematite was sintered in a 5 kg. experimental induced draft sintering apparatus, studying the effect of varying draft, amount of fuel, H_2O additions, content of fines, and amounts of other materials, such as SiO_2 and CaO. The passage of air through materials of varying degrees of fineness and H_2O content was determined. Maximum temperatures in the hottest zone ran above 1600° C. and the material became fused temporarily. Increasing amounts of fuel increased sintering time, increased draft decreased time. According to the chemical composition of the raw material, there could be obtained as newly-formed substances, magnetite, little hematite, Fe silicate, Ca ferrite, Ca silicate and glass. The size of pieces and suitability of the sinter were affected by amount of fuel used, draft, and chemical composition. Composition of material influences softening of sinter at high temperatures. Appreciable change in porosity could not be obtained by varying sintering conditions. Reduction by H at 600° C. showed that formation of compounds of Fe oxide with CaO or SiO_2 caused decrease in amount of reduction. When both CaO and SiO_2 are present in raw material in sufficient quantities, a formation of $CaSiO_3$ results; no harmful effects are caused when this sinter is used in the blast furnace. Includes 18 references. All results were confirmed on a 20 kg. sintering apparatus with a 33 × 33 cm. hearth surface. DTR (31)

Author Comments on Cyanides. Wm. McConnachie, (Coltness Iron Works). *Blast Furnace & Steel Plant*, Vol. 19, Nov. 1931, pages 1474-1478.

Reply to S. P. Kinney's discussion in Aug. 1931 issue of author's "Importance of Cyanides in Iron Smelting" published in the July 1931 number. Of the data in U. S. Bureau of Mines Technical Paper 390 showing cyanide and alkali in gas from the slag notch of a blast-furnace, only that sample containing the greatest amount of cyanide should be regarded as approximately representing the concentration of alkali in the gas of the well when in good working order. The high alkali concentration of this sample is not due to projected accumulations. Cyanides leave the well as vapor, but need not rise to any great height in the furnace before they are destroyed in decomposing Fe silicate. Intercepted alkalies return to the well as a thin liquid primary slag, running much ahead of the solid materials. This rapid circulation of the alkalies in the bottom of the furnace enables them to do the vast amount of work which must be credited to their transformation. MS (31)

The Handling of Pig Iron. Arthur E. Linnell. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 120-124.

A discussion (1) of handling and molding methods in the sand casting of pig Fe and (2) of pig casting machines. CHL (31)

Economics of the Hot Air Blast. J. B. Fortune. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 115-119.

The mechanical devices which make for greater efficiency in the production of high-temperature hot blast, such as burners, valves, etc., are discussed. CHL (31)

Rapid Wear of Blast Furnace Hearths. A New Method for Cooling. (Usure rapide des cuves de hauts-fourneaux. Un nouveau mode de réfrigeration). A. Cousin. *Revue de Métallurgie*, Vol. 29, Feb. 1932, pages 57-60.

The use of H_2O for cooling hearth and boshes of a blast furnace is satisfactory, but much better efficiency and greater life of the lining can be obtained by cooling with air. A 35 kwh. blower supplies enough air for a 300 ton stack. Holes 4.5 cm. in diameter and about 40 cm. long are provided in the bricks and the air is fed into them. With this arrangement, using 1700 holes, the cooling surface for a 300 ton furnace is 99 m.^{2}. The regulation of cooling is quite flexible and efficient and the uniformity of cooling is greatly increased. The first stack so equipped at Seraing Works of Societe Cockerill has lasted twice as long as any water cooled one and still no wear can be detected. JDG (31)

Efficiency of Blast Furnace Gas Disintegrators. I. N. Goff & T. S. Washburn. *Blast Furnace & Steel Plant*, Vol. 19, Nov. 1931, pages 1462-1466.

The efficiencies of 2 types of gas disintegrators and towers of the Brassert type recently installed in the Chicago district, methods of use and calculations are described. Results of 8 of 13 tests made show that the lowest dust content is obtained with the 4-bar type of disintegrator which gave a gas containing 0.0095 grains of dust/ft.^{3} of gas. An improved 4-bar type running at another plant in the same district is attaining the same results as to cleanliness, while the h.p. is comparable to that of the 3-bar machine. Minimum dust content obtained with the 3-bar type is 0.002 grains/ft.^{3}. There is an ideal H_2O flow above or below which the dust content increases. Average analysis of dust collected was 21.86% SiO_2, 8.11% Fe_2O_3, 17.16% Al_2O_3, 27/74% CaO, 5.36% MgO, 1.47% MnO and 15.62% C, S and alkalies. There was apparently no relation between the composition of dust and the cleanliness of the gas. The extreme fineness of the dust delivered by the gas to a stove favors its being carried through with the stack gases. MS (31)

Manufacturers' Literature Reviews

412 **Forging Furnaces**—The Electric Furnace Co., Fuel Division, Salem, Ohio, has for distribution, a reprint of an article illustrating and describing various types of continuous and batch type forging furnaces with automatic temperature control, used in modern forge shop practice. The furnaces illustrated include pusher, rotary, slot type, multi-door batch type, forging and rotary end heating furnaces. This company will also supply reprints of an article dealing with a novel semi-continuous furnace for low cost production nitriding and one devoted to a new fuel fired car type furnace of latest design.

413 **Illium**—A booklet prepared by the Burgess-Parr Company, Moline, Ill., gives a short sketch of the development of Illium, a corrosion resistant non-ferrous alloy, gives charts comparing it with other alloys and describes its physical properties. Suggestions for its application in various industries are given together with illustrations of a variety of delicate and odd shaped parts which have been made from Illium.

414 **Copper Plumbing**—Bulletin No. 39 of the Parker Appliance Co., 10320 Berea Road, Cleveland, Ohio, illustrates their new line of copper plumbing fittings.

415 **Industrial Application of the X-Ray**—Bulletin No. 284 of the General Electric X-Ray Corporation, Chicago, Ill., presents several extracts from authorities identified with this branch of science and supplements them with a series of specific cases of the application of X-rays in industrial work.

416 **Alloy Steel and Alloy Iron**—Bulletin 528 of the Mackintosh-Hemphill Co., Pittsburgh, Pa., describes in a brief way their alloy steels, Machempite, Machempite A, B, and C and their alloy iron, Iralite. The general properties of each alloy are given together with suggested applications.

417 **Grinding**—The feature article in the May issue of *Grits & Grinds*, published by the Norton Company, is "Correct Wheels Required for Grinding the Cutting Carbides." It is well illustrated.

418 **Refractories**—Bulletin No. 3, 1930, of the Atlas Lumnite Cement Co., Inc., Chrysler Building, New York, N. Y., is a popular technical discussion of "Lumnite," a new type of binder for making refractory concrete linings, shapes and mixtures. Bulletin No. 3, 1931, is a manual for making heat-resisting, non-spalling concretes suitable for refractory linings in fire doors, furnaces, cupolas, etc.

419 **Microscopes**—The Bausch & Lomb Optical Co., Rochester, N. Y., has issued an attractive booklet on their new comparison microscope for studying evidence. This instrument is designed for the examination and comparison of bullets, shells, finger prints, textiles, or any microscopic material calling for the use of low magnification.

420 **Exhaust Fans**—Bulletin No. 166 of the Duriron Co., Inc., Dayton, Ohio, covers the engineering and mechanical features of Duriron fans for the ventilation of pickling rooms, laboratory hoods, etc. The physical and chemical properties of Duriron, which make up all parts of the fans coming in contact with fumes, are discussed in Bulletin 150.

421 **X-Ray and the Foundry**—The Kelley-Koett Mfg. Co., Inc., Covington, Ky., has published an attractive pamphlet on the application of X-rays to the inspection of castings and welds. Several radiographs are reproduced and explained.

422 **Refractory Brick**—A circular descriptive of their new Laclede Mullite brick has been issued by the Laclede-Christy Co., St. Louis, Mo.

423 **Gas Indicator**—The M-S-A combustible gas indicator was developed for practical use in detecting flammable gases and vapors. It is described in a circular sent out by the Mine Safety Appliances Co., Pittsburgh, Pa.

ALPHABETICAL INDEX TO ADVERTISERS

◆ ◆ ◆

424 **Condenser Tubes**—A pamphlet describing Anaconda super-nickel and Ambrac condenser tubes has been issued by the American Brass Co., Waterbury, Conn. Physical characteristics and specifications for these tubes are given.

425 **Cadalyte**—An attractive 30 page booklet issued by the Grasselli Chemical Co., Cleveland, Ohio, provides essential data on the properties, application and uses of cadmium and Cadalyte, a process and product for cadmium plating. The booklet is well illustrated.

426 **Magnetic Separators**—A treatise of the separation of such feebly-magnetic substances as iron oxide, garnet, hematite, slate and wolframite from non-magnetic substances is included in a new bulletin published by Dings Magnetic Separator Co., Milwaukee, describing the new Dings Type IR Super-High Intensity magnetic separator.

427 **Artificial Furnace Atmosphere**—The Ajax Electric Company, Philadelphia, is distributing reprints of an article entitled "Artificial Furnace Atmosphere Created from Ammonia."

428 **Matrix Alloy**—The Cerro de Pasco Copper Corporation, New York, N. Y., has compiled a 30-page booklet devoted to their new alloy of bismuth, lead, tin and antimony. It gives full information on the application of this alloy, together with many sketches, for assistance to the tool and die designer. The same company has issued reprints of an article entitled "Bismuth, Essential to Fusible Alloys, has Additional Possibilities."

429 **Stainless Steel Castings**—A pamphlet prepared by the Cooper Alloy Foundry Co., 150 Broadway, Elizabeth, N. J., contains a table giving various analyses of their stainless steels together with suggested uses for each one. A table comparing the physical properties of castings made from these steels with those from other materials is given.

430 **Acetylene Torch**—Bulletin No. 200 of the Vulcan Copper & Supply Co., Cincinnati, Ohio, is devoted to their Model B-2 acetylene torch. It describes the torch itself and illustrates and discusses the welding and cutting tips for special purposes which increase its usefulness.

431 **Furnaces**—Bulletin No. 34 of the W. S. Rockwell Co., New York, discusses their continuous bright annealing furnaces, both electric and fuel fired. A sketch of a typical special-atmosphere flex-belt conveyor furnace is given.

432 **Lead**—The July issue of this publication of the Lead Industries Association, New York, contains short articles on a number of interesting uses of lead.

433 **Furnaces and Furnace Equipment**—Two recent bulletins of the Surface Combustion Company, Toledo, Ohio, are of interest. One describes an installation of their cast alloy Conveyor Hardening Furnace at the Flannery Bolt Company, giving operating data and illustrations of various types developed for different work. The other bulletin shows several of their 46 types of burners which are furnished in more than 400 different sizes.

434 **Whiting Founder**—The first issue of a new quarterly publication of the Whiting Corporation, Harvey, Ill., contains several interesting articles devoted to cast iron.

435 **Expansion Joints**—A new illustrated bulletin of 8 pages describes in detail the "Flexodisc" packless expansion joint suitable for handling expansion in steam mains, miscellaneous piping and for special expansion problems, available in sizes from 3" to 30", the expansion element being of alloy steel. Croll-Reynolds Engineering Co. Inc., 17 John St., New York.

PROPERTIES OF METALS (1)

Metallurgy of Copper. V. Y. Mostowitch. Siberian Scientific Technical Library, Tomsk, 1931, in Russian. Paper, 6 x 9 inches, 372 pages. Price 6 rubles.

Looking through the pages of Professor Mostowitch's work one finds an average college text book without any particular advantages or glaring defects, except the poverty of technical terminology. Normal adaptation of foreign terms to any language takes a considerable time even under healthy conditions of industrial development, but the transplanting of Montana shop vernacular into the heart of Siberia by simply transcribing English words with Russian characters is not the way of solving this problem. Newly coined names of processes and operations cannot escape such handling without some difficulty but transcription of "cake," "bottom," "kiln," etc., borders on the ridiculous.

It is reading between the lines which gives to the book a particular interest. This is a Russian book for Russian students, but it does not contain a single description of any plant in that country. Besides the usual official buncombe regarding copper production in the years to come not a single figure is given bearing on home situation. Either a professor of metallurgy does not know that there is a copper industry in his native land, or its state is not fit even for home consumption. Amusing or tragic, depending on the viewpoint, but always acutely significant is the need for recurring to, say, Idaho figures when dealing with any subject from the workability of copper deposits up.

From a metallurgical standpoint the book is practically of no interest to the outside world; as a mirror of the present conditions it is quite amusing, and Professor Mostowitch undoubtedly deserves many thanks for his efforts to resurrect a part of Russian technical literature. (1)-B-

Metallurgy of Nickel. V. Y. Mostowitch. Siberian Scientific Technical Library, Tomsk, 1931, in Russian. Paper, 6 x 8 inches, 105 pages. Price 1.40 rubles.

In the whole scientific literature it would be difficult to point at any single work exhaustively covering all phases of nickel manufacture and its properties. Many good books are available but a perusal of many will be required before a complete picture will appear before the eyes of the reader, so that in Russia the process of obtaining adequate information would become particularly difficult and lengthy. Professor Mostowitch did much to relieve this situation by compiling from the world's literature a set of data presented in this booklet. The whole field is covered, though somewhat briefly, particularly in applications of nickel, where the text becomes almost sketchy. One feels that the pamphlet will find a hearty welcome among the students of Russian schools for which it is intended. (1)-B-

Investigation of the Glow-Electric Emission of Metals in the Neighborhood of Their Melting Points. (Untersuchung über die glühelektrische Emission von Metallen in der Umgebung ihres Schmelzpunktes.) Irmgard Ameiser. *Zeitschrift für Physik*, Vol. 69, Apr. 23, 1931, pages 111-140.

Cu, Au and Ag were tested by a new method which avoids falsification of the test results by emission of the containers. The emission energy for the solid and liquid state is independent of temperature. Ha (1)

The Theory of the Fine Structure of the Magnetization Curves of the Single Crystals. (Zur Theorie der Feinstruktur der Magnetisierungskurven der Einkristalle.) N. Akulov. *Zeitschrift für Physik*, Vol. 69, Apr. 23, 1931, pages 78-99.

Previously developed methods are extended so that they permit a more exact calculation of the magnetization curves of single crystals. The values thus calculated for Fe agree well with tests made by other investigators. Ha (1)

Magnetism in Discontinuous Media. L. W. McKeehan. *Revue Modern Physics*, appendix to *Physical Review*, Vol. 2, Apr. 1930, pages 477-505.

The various theories of magnetism are reviewed and in particular the modern theory of ferromagnetic crystals is treated. Ha (1)

The Anisotropy of the Magnetization of Ferromagnetic Crystals. (Zur Anisotropie der Magnetisierung ferromagnetischer Kristalle.) F. Bloch & G. Gentile. *Zeitschrift für Physik*, Vol. 70, July 6, 1931, pages 395-408.

The paper discusses and calculates the dependence of the magnetizing energy on the direction of the crystal. Ha (1)

On Molecular and Atomic Volumes. XXXII. The Atomic Volumes of the Elements at the Absolute Zero Point. (Ueber Molekular- und Atomvolumina. XXXII. Die Nullpunktsvolumina der Elemente). Wilhelm Biltz & Karl Meisel. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 198, May 28, 1931, pages 191-203.

The densities and atomic volumes of the elements at ordinary temperatures and the atomic volumes at — 273° C. are tabulated. WHB (1)

A Thermal Effect Shown by Bismuth and Related Metals. (Ueber einen Warmeeffekt beim Wismut und verwandten Metallen.) L. Bergmann. *Physikalische Zeitschrift*, Vol. 32, Aug. 1, 1931, pages 584-585.

Majorana found that if a piece of Bi inserted axially into a small coil of many turns of wire be illuminated by intermittent light, then electric currents are produced in the coil. This effect has now been observed with Sb, Mg, Cd, Zn, Sn, the "elektrometall" alloys CM and ACM, a special bronze, and alloys containing Bi and Sb. The effect is shown most strongly by Bi. Sb comes next in order. It is shown that the effect is partly thermoelectric in character, and partly of unknown, but possibly of photoelectric origin. WHB (1)

Beryllium in Industry. (Das Beryllium in der Technik.) Johannes Becker. *Zeitschrift für die gesamte Giessereipraxis, Das Metall*, Vol. 52, May 24, 1932, pages 58-59.

The physical and mechanical properties of Be and its use in industry are described. It has already many applications, and these are rapidly increasing in number. WHB (1)

Properties of Metallic Cadmium. (Eigenschaften des metallischen Kadmiums.) Thews. *Die Metallbörse*, Vol. 21, Apr. 25, 1931, pages 772-773; May 2, 1931, page 820.

Physical, chemical and technological properties of Cd are summarized. EF (1)

The Specific Resistance of Thin Metal Layers, Especially of Silver and Tungsten. (Untersuchungen betreffend den spezifischen Widerstand dünner Metallschichten, insbesondere bei Silber und Wolfram.) L. Hamburger & W. Reinders. *Recueil des Travaux Chimiques des Pays-Bas*, Vol. 50, April 15, 1931, pages 441-474.

Thin layers of Ag were formed by sublimation and condensation on glass walls. The thickness of the layer was calculated from the weight of the layer and the density of the metal by assuming this to be the normal density of the compact metal. The average thickness of the Ag layer formed at room temperature was 16 atoms, of the W layer 1 atom. At — 185° C. each metal layer was 2 atoms thick. From measurements made at room temperature and at the temperature of liquid air, it is concluded that the specific resistance of thin metal layers depends upon the metal employed, the thickness of the layer, the type of formation, the temperature and changes in temperature, the foundation upon which the metal is deposited and other influences. The specific resistance of thin layers is greater than that of the massive metal, the deviation being the greater, the more refractory the metal and the lower the temperature at which condensation takes place. W layers 2 $\mu\mu$ thick formed at — 185° have a negative temperature coefficient. Thin layers of both Ag and W are attacked by moist O, but not to any great extent by the dry gas. Ha (1)

The Structure of Thin Metal Layers, Especially of Tungsten and Influence upon the Specific Conductance. (Zur Struktur von dünner Metallschichten, im besonderen von Wolfram und deren Einfluss auf die spezifische Leitfähigkeit.) W. Reinders & L. Hamburger. *Recueil Travaux Chimiques Pays-Bas*, Vol. 50, April 15, 1931, pages 475-490.

See preceding abstract. From probability calculations it is concluded that the thin layers of W that have condensed at low temperatures upon glass and quartz possess a completely amorphous structure. In thicker layers and at higher temperatures the atoms group themselves into a crystalline orientation. The high specific resistance of thin metal layers is assumed to be due largely to the abnormally large spacing between atoms. The negative temperature coefficient of W is attributed to the increase in thermal motion at higher temperatures. As the thickness of the layers increases, the atoms arrange themselves in a more orderly manner and with a decreased spacing; the temperature coefficient can finally become positive. In the case of less refractory metals, the grouping of the atoms may result in grains of small coherence, so that the condition is noticeable only at greater thicknesses. Nonmetallic inclusions can likewise lower the condition. Ha (1)

The Principal Factors in the Castability of Pure Metals. (Facteurs principaux de la coulabilité des métaux purs.) A. Portevin & P. Bastien. *Comptes Rendus*, Vol. 194, Feb. 15, 1932, pages 599-601.

F being the freezing point of the metal, θ_1 its casting temperature, θ_2 the temperature of the mold, it is evident that the length λ of the spiral ordinarily used in testing the fluidity of metals increases inversely with F-θ_2, becoming infinite when θ_1 equals F. The lowest temperature of casting increases with θ_1-F, the more so as the specific heat c, the density d, and the latent heat of solidification L of the metal are increased. The most simple expression for fluidity is then given by the formula

$$\lambda = \mathrm{K.d}\frac{c(\theta_1 - F) + L}{F - \theta_2}$$

Mathematical analysis of the phenomenon of fluidity leads to a more complex formula which for low values of $(\theta_2 - F)/F$ (less, for example, than half) reduces to

$$\lambda = \alpha\frac{d.c(\theta_1 - F)}{F - \theta_2} + \beta\frac{L.d}{F - \theta_2}$$

where α and β are coefficients depending upon the dimensions of the mold and the nature of the material forming it, on the height of pouring, and also (but in a proportion which it is difficult to define) on the viscosity of the metal. The authors give a series of curves, showing the relationship between λ and $\theta_1 - F$ for Sn, Cd, Pb, Zn, Sb, and Al and showing that the fluidity is a linear function of temperature. They likewise show that the coefficient β varies little from one metal to another and that the viscosity does not seem to affect it. Further, the coefficient α varies from one metal to another and is a function of the viscosity. The authors believe that the forces of surface tension do not appear to play an important part in fluidity. In the case of the mold which they use, calculation shows that the magnitude of these forces is in the neighborhood of 200° C. In conclusion, they state that fluidity is a result of complex factors, among which the thermal properties (specific heat, latent heat of solidification, freezing point) of the metals play a part quite as important as their viscosity. OWE (1)

The Allotropic Transformation of Barium in the Solid State. (Sur une transformation allotropique du baryum a l'etat solide.) E. Rinck. *Comptes Rendus*, Vol. 193, Dec. 21, 1931, pages 1328-1330.

A description of the preparation of pure barium by means of the Guntz process is followed by the results of experiments designed to determine certain of the physical constants of the metal.

Fusion point		710° ± 2° C.
Electrical conductivity	(0° C.)	0.28 x 10^5
" "	(18° C.)	0.25 x 10^5
Temperature coefficient of resistivity	(0° C. to 100° C.)	0.0061
Density	(17.2° C./4° C.)	3.740

The author reports that barium undergoes an allotropic transformation at 375° C., the α form being stable below this temperature and the β form being stable between this temperature and the fusion point. OWE (1)

Cadmium. W. G. Rumbold. *Mining Journal*, Annual Review No., Feb. 13, 1932, page 11.

Properties and uses are discussed. AHE (1)

Special Bronzes for Telephone and Telegraph Wires. (Spezialbronzen für Telephon- und Telegraphendrähte.) F. FREUDE. *Die Metallbörse*, Vol. 21, Aug. 8, 1931, pages 1491-1492; Vol. 21, Aug. 15, 1931, pages 1539-1540; Sept. 5, 1931, pages 1673-1674.

The Austrian, Roumanian and Polish specifications for telephone and telegraph bronze wires regarding ultimate strength, bending properties and electric conductivity are tabulated. The peculiar melting and casting operations to meet the electrical requirements are described in detail. The deoxidizers, mainly Cd, and the other additions to improve the physicals, mainly Si and Sn, are quantitatively given. The rolling operations are fully outlined and data on the succeeding roll passes are stated and the sections illustrated. The balance of the paper considers the production of these special bronze wires by cold drawing and details the reductions in the wire's cross sections. Particular emphasis is placed on proper lubrication technique. EF (2)

Alloys of Lanthanum and Aluminum (Le leghe tra lantanio e allumimio). G. CANNERI. *La Metallurgia Italiana*, Vol. 24, Feb. 1932, pages 99-103.

Thermal analysis indicates the existence of LaAl, $LaAl_2$ (m.p. 1424° C.) $LaAl_4$ (m.p. 1222° C.). There is a eutectic at 80 atomic % La, 20 atomic % Al and 542° C., and one at about 97 atomic % Al, 3 atomic % La and 658° C. La Al_4 inverts from the β to the α form at 816° C. The equilibrium diagram is drawn on the basis of the thermal analysis and some microscopic evidence. Solid solubility limits were not determined, nor were X-ray studies made. Moist air slowly attacks the alloys high in La, especially those containing free La. Those high in Al are quite stable, the surface remaining bright. The hardness is stated not to vary much from that of the pure metals up to 35 atomic % Al on the La side and between 100 and 80 atomic % on the Al side. Hardness values are not given. Maximum hardness (6 on the Moh scale) is at the composition La Al_2, and that compound is exceedingly brittle. From 60 to 75 atomic % Al the alloys disintegrate spontaneously. This is thought not to be due to an inversion of La Al_2 but rather to the effect of gas pressure due to reaction of carbide, as impurity, with atmospheric moisture, shattering the brittle alloy. The purity of the La and Al used is not stated. Cooling curves only were apparently used. The mass of alloy used in the thermal analysis is not stated. HWG (2)

Bearing Metals and Their Behavior in Operation. (Die Lagermetalle und ihr Verhalten im Betriebe.) KUNZE. *Maschinenbau*, Vol. 10, May 1931, pages 664-670.

General directions for the selection of bearing metals are developed, their basic properties, testing methods and equipment are described and test results reproduced. Ha (2)

Aluminum Alloys. F. KELLER (Aluminum Co. of America) *Metal Stampings*, Vol. 5, Feb. 1932, pages 43-46, 129-130.

Commercially pure Al in the annealed state has a tensile strength of about 13,000 lbs./in.², increased to 24,000 lbs./in.² by cold working. Much stronger alloys are made by adding one or more of the constituents Cu, Mg, Si, Mn and Fe. The names and distinctive numbers of the principal Aluminum Co. of America alloys, their chemical compositions, industrial uses and suitability for castings (either sand or permanent mold), forging, cold working or heat treating are given in some detail. Alclad 17S is Duralumin 17S with thin integral surfaces of pure Al. It shows high resistance to atmospheric corrosion, the more so since the core is electrolytically protected by the Al and small scratches or bruises on the surface do not become nuclei for corrosion. CMB (2)

Electric Properties of Diluted Solid Solution Alloys. I. Gold Alloys. (Elektrische Eigenschaften verdünnter Mischkristallegierungen.) J. O. LINDE. *Annalen der Physik*, series 5, Vol. 10, 1931, No. 1, pages 52-70.

Study of a series of alloys of Au with Cu (0.94 and 3.15%), Ni (1.16, 2.14 and 3.05%), Co (0.95, 2.11 and 2.65%), Fe (1.07, 1.89, 2.17 and 3.32%), Mn (0.77 and 2.08), Cr (1.8 and 2.84%), Ag (0.99, 1.88, 2.87 and 2.93%), In (0.86 and 1.68%), Sn (0.93, 1.81 and 3.02%), Pd (1.15, 2.88 and 4.46%), Pt (0.99, 1.96 and 3.0%), Rh (0.24, 0.50, 1.05, 2.09 and 3.03%), Ru (0.83, 1.84 and 2.78%), Ir (0.99, 1.82 and 2.76%) and Os (0.96, 1.84 and 2.96%). Temperatures: from 20° to -190° C. The results are tabulated; it is shown that the atomic increase of resistance does not always increase with increasing, horizontal distance of the dissolving and the dissolved metal; the transition elements show exceptions. Ha (2)

Some Non-Ferrous Engineering Alloys. WESLEY LAMBERT. *Institution Engineers & Shipbuilders in Scotland, Advance Copy*, 1930, pages 1-19.

The use of non-ferrous alloys is not justified on the grounds of strength and hardness alone, on account of the superior mechanical properties of carbon and alloy steels, but is favored by engineers from considerations of resistance to corrosion, thermal conductivity, anti-frictional qualities and artistic attractiveness. The mechanical proporties and application of brass, manganese-brass, aluminum-bronze, phosphor-bronze, lead-bronze, Monel-metal and anti-friction white metals are dealt with and also the methods of compounding and handling these alloys. The desirable properties of an anti-friction-bearing lining are fully discussed and the virtues of a tin-base Babbitt as against those of a lead-base metal, compared. See also *Metals & Alloys*, Vol. 2, Mar. 1931, page 62. (2)

A Corrosion Resisting Aluminum Alloy. (Eine korrosionsbeständige Aluminiumlegierung.) HANS WOLF. *Die Chemische Fabrik*, Vol. 4, Dec. 30, 1931, pages 493-494.

Contains 3 references. An alloy called AW 15 developed by the Aluminium-Walzwerke Singen contains less than 2% Mn and the balance Al with the usual Fe and Si impurities. Its corrosion resistance tested by several different methods is better than that of pure Al. In 1 mm, sheet form, soft temper, it has a tensile strength of 11.8 kg./mm.² elongation 27%, Brinell hardness 32, hard temper tensile strength 26 kg./mm.², elongation 3% and Brinell hardness 59. Its deep drawing qualities are almost as good as pure Al and it can be satisfactorily cold rolled and stamped. After cold working it should be annealed at 500 to 520° C. It can be electroplated, soldered and welded. CEM (2)

Heredity Influences on the Quality of Cast Iron. Correspondence from A. PORTEVIN, Paris, France. *Metal Progress*, Vol. 21, Jan. 1932, pages 71-72.

Summarizes briefly the problem indicated as important at the Milan Exhibition and deplores a tendency on the part of foundrymen to assign a significance to those phenomena of heredity and oxidation which is not justified by the facts. WLC (3)

A Low Alloy Steel for Large-Tonnage Applications. A. B. KINZEL. (Union Carbide & Carbon Research Laboratories, Inc.). *Iron Age*, Vol. 128, Dec. 31, 1931, pages 1686-1688.

Deals with a series of alloy steels chiefly composed of Cr, Mn and Si, and to which the name of Cromansil has been given. The need of a superior structural alloy steel led to the development of Cromansil steels. The best balance of alloy content is achieved by the following analysis range: Cr—0.4 to 0.6%; Mn—1.1 to 1.4%; Si—0.7 to 0.9%. This may be varied for special applications. Solidification of Cromansil steels in the ingot is different from that of either straight Cr or Mn steels; segregation is low and dendrites are small. The low cost combined with other desirable features indicates their use in many applications. VSP (3)

The Permanent Growth of Gray Cast Iron. W. E. REMMERS. *Fuels & Furnaces*, Vol. 9, Apr. 1931, pages 455-456.

Abstract of a paper presented before the Chicago section of the American Institute of Mining & Metallurgical Engineers. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. (3)

Steel-Like Cast Iron Made in Cupola. (Stahlähnliches Gusseisen aus dem Kupolofen.) M. REISSERT. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Feb. 7, 1932, pages 56-58.

The paper briefly reports the test results on cast irons which were made according to the Corsalli method with a C content between 1—2%. Such a cast iron has tensile strengths of from 64,000 to 75,000 lbs./in.² and can be made in the cupola without difficulties. GN (3)

A Comparison Between the Physical Properties of Rails Produced by the Open-Hearth and Duplex Processes. E. A. WRAIGHT (Metallurgical Inspector, Indian Stores Department). Government of India Central Publication Branch, Calcutta, 1931. Paper, 6¼ x 9¾ inches, 18 pages. Price 1 Rupee.

Rails made by the Tata Iron & Steel Company were tested. Open-hearth and duplex heats were cast into 3 and 5 ton ingots, and 90 lb. rails rolled therefrom. Some rails were rolled direct, others from reheated blooms (wash heat), and still others from blooms cooled overnight and reheated. Tensile and drop tests are reported. The C ran between 0.55 and 0.65%, Mn from 0.75 to 0.90%. The C composition of the duplex heat was intermediate between those of the open-hearth heats, but higher in Mn than either. The deflection of duplex on the drop test was intermediate to those of the open-hearth heats, as was the tensile strength, but the elongation was a trifle lower than even that of the higher C open-hearth heat. The duplex rails are adjudged equivalent to open-hearth. There was some indication that rails tend to show slightly higher deflection on the drop test when rolled from reheated blooms, and the rails from ingots toward the end of a cast showed the same tendency. No notable difference in grain size was noted on rails from the 3 and the 5 ton ingots. Grain size was, however, slightly larger in rails from wash-heated blooms. HWG (3)

The Production of 18-8 Steel Wire. W. H. WILLS & J. K. FINDLEY. *Rolling Mill Journal*, Vol. 5, Oct. 1931, pages 671-673.

The procedure of drawing and reheating and the mechanical properties of this corrosion resistant material are described. See *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 56. Ha (3)

Characteristics of Alloyed Cast Iron. F. W. SHIPLEY, *Transactions American Society for Steel Treating*, Vol. 19, No. 2, 1931, pages 165-181.

Discussion. Previously abstracted as Preprint No. 29, 1931. See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 31. WLC (3)

Magnetic Properties of Gold-Iron Alloys. J. W. SHIH. *Physical Review*, Vol. 38, Dec. 1931, pages 2051-2055.

The alloys of Au and Fe of different composition ranging from 0.07 to 10% Fe by weight have been studied. It was found that the alloys containing 0.1 to 5% Fe are paramagnetic. Their susceptibilities decrease with rising temperature in a characteristic way, but do not follow either Curie's law or Weiss' law exactly. The square root of the susceptibility increases linearly with the percentage of Fe atoms added. Thus the Au-Fe series does not show the same property as the Ni-Cu alloys whose susceptibility increases with temperature in certain ranges. The behavior of the Fe atoms in the alloy and some correlations between magnetic susceptibility, density and melting point are discussed. WAT (3)

Ferrous Alloys. W. P. SYKES. *Conference on Metals and Alloys, Case School of Applied Science*, Cleveland, Ohio, Nov. 1931, Paper No. 8, 7 pages. Mimeographed.

General discussion of atomic arrangement, structure and properties under heat-treatment and age-hardening, with special attention to the Fe-W alloys, including those with Mo or Co also. No illustrations are included with the mimeographed paper. These, shown as lantern slides in the presentation at the conference, are essential to a good understanding of the paper. HWG + Ha (3)

Steel Castings meet Requirements. *Foundry*, Vol. 59, Dec. 1, 1931, pages 58-59.

Castings to withstand pressure must be free from internal defects, and made from dense homogeneous metal. Soundness, density, and strength in steel castings is influenced by the deoxidation of molten metal. Research in steel castings production has made available a wide range of alloy steels and special heat treatments. Metal analysis and heat treatment control Brinell hardness. Steel which will withstand high pressures does not necessarily stand up at elevated temperatures. Steel castings of certain analyses have been found to meet these conditions successfully. VSP (3)

Measuring the Strength, Plasticity and Toughness of Tool Steels. J. V. Emmons (Cleveland Twist Drill Co.). *Iron Age,* Vol. 128, Dec. 24, 1931, pages 1614-1619.

From a paper presented before the American Society for Testing Materials in Chicago. Reviews previous investigations on mechanical properties of hardened tool steels. It considers various methods used for measuring such properties. A new method of measuring the properties of strength and plasticity in hardened steels, known as the torsion test, is described. From the measured properties of strength and plasticity, a value known as the coefficient of toughness is calculated. By this method, a study is made of the properties of a typical tool steel over a wide range of heat treatment. Conclusions are drawn as to the nature of the steel investigated. See "Some Physical Properties of Hardened Tool Steel," *Metals & Alloys,* Vol. 2, Oct. 1931, page 205. VSP (3)

Characteristics of Alloy Steels. III. Geo. M. Enos. *Modern Machine Shop,* Vol. 4, Feb. 1932, pages 26-30.

The troubles occurring often in heat-treating alloy steels are generally discussed, for instance too soft, soft spots, too hard, too brittle, warping, scaling, pitting; means of overcoming these are briefly treated. Ha (3)

Case-Hardening Steels. (Einsatzstähle.) E. Eichwald. *Automobiltechnische Zeitschrift,* Vol. 35, Feb. 10, 1932, pages 59-64.

This article deals with steels which have been given, by a suitable heat treatment, a uniformly fine structure, high tensile properties and a glass-hard surface. The German standardized steels (6) and 82 other products are listed and their physical properties, heat treatment and application described. Ha (3)

Weight of Hot Rolled and Cold Rolled Strip Steel. J. K. Olsen. *Metal Stampings,* Vol. 4, June 1931, page 528.

This table gives the weight in lbs./ft.² of hot rolled and cold rolled strip steel from 00000 Birmingham Gage (=0.500 in.) to 36 Birmingham Gage (=0.004 in.). Hot rolled steel weighs 487.3 lbs./ft.³ and cold rolled steel weighs 489.6 lbs./ft.³ JN (3)

A New Iron of German Origin. *Chemical Age,* London, Vol. 26, Metallurgical Section, Jan. 2, 1932, page 1.

A new special iron, called "migra iron" (abbreviated from micrographite) to mark its fine-fractured structure and its fine-grained graphite, is being manufactured by the Vereinigte Stahlwerke, Germany, and also, in a form poor in phosphorus, at the Friedrich-Wilhelm smelter in Muhlheim. Prof. Piwowarsky, of Aachen, reported on the use of this new iron for foundry purposes at the annual meeting of the Verein Deutscher Eisengiessereien, Berlin. The difficulty in its manufacture lies in a very definite intermediate heat treatment of the crude liquid Fe according to the principles of superheating melts. The total C and graphite content of the migra iron so obtained is lower, whereas the bending strength and Brinell hardness are higher. VVK (3)

Relation Between Magnetic Properties, Impact Strength and Hardness. H. Styri. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 94-106.

Includes discussion. See abstract of preprint. *Metals & Alloys,* Vol. 2, Oct. 1931, page 206. HWG (3)

The Common and Special Steels. (Gli Acciai Comuni e Speciali.) G. Guzzoni. Ulrico Hoepli, Milan, 1932. Paper, 6½ x 9½ inches, 471 pages. Price 60 lire.

The properties, structure, physical and mechanical properties, methods of testing, effects of impurities and gases, behavior in freezing, hot and cold working, and heat-treatment, of carbon steels are first discussed, then the common alloy steels, high speed and magnet steels, and the high Cr and 18-8 types. Carburizing and nitriding, and metallographic methods of identification of constituents and inclusions are also dealt with.

The treatment is remarkably up-to-date. Each section has a selected bibliography, comprising standard books, mostly recent ones, and a well-chosen list of periodical references of the vintage of 1927-1931. Guzzoni is very conversant with the important investigations of American, German, British and French metallurgists and has utilized the newer information in effective style. Probably more emphasis is put on Hanemann and Schrader's theories of martensite, and on "accelerated" methods of determining endurance limit and high temperature creep properties than they deserve. On the whole, however, the choice of material and the emphasis put on it is very good.

The volume is well printed and well indexed. On account of its being so up-to-the-minute, and its contents so well chosen, it is a very useful reference book even to those who read Italian with less facility than other languages in which metallurgical information is published. The quality of recent Italian metallurgical articles and treatises is so good that, if it is kept up, an English-speaking metallurgist will probably find a reading knowledge of Italian more useful than of any foreign language save German. H.W. Gillett (3) -B-

Hardness, Microstructure and Temperature Coefficient of the Electric Resistance of the Iron-Platinum-Alloys. (Härte, Mikrostruktur und Temperaturkoeffizient des elektrischen Widerstandes der Eisenplatin-Legierungen.) W. A. Nemilow. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 204, Feb. 9, 1932, pages 49-59.

All Fe-Pt alloys are magnetic at room temperature, with increasing content of Pt the magnetizability decreases. The method of making these alloys in the Krystol-furnace and in the oxy-hydrogen flame is described. The hardness curve is irregular with 2 maxima for the annealed alloys which points to the existence of 2 solid solutions at about 35-40 and 60-70% Pt. The microstructure shows a more or less definite pattern of straight lines. The curve of the temperature coefficient drops irregularly with the Pt-content and has 2 minima. 9 references. Ha (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Reactions with Liquid Chlorine. (Ueber Reaktionen mit flüssigem Chlor.) J. Meyer & W. Aulich. *Zeitschrift für angewandte Chemie,* Vol. 44, Jan. 1931, pages 21-23.

A number of metals were tested to determine their behavior in contact with liquid Cl at temperatures up to 140° C. Te and Se formed the tetrachloride at —80° C.; V shows a sudden violent reaction at room temperature. Gold is chlorinated completely at moderate temperatures, but with Ag, the film of silver chloride forms a certain protection against further chlorination; Pb also shows only a surface action. Cr and Mn react only if a little water is added. Si and crystalline B are very resistant. Ha (4)

The Evaluation of Production Corrosion Losses. Stanley Gill & Fred W. Karl (Gulf Oil Companies). *Proceedings American Petroleum Institute,* Dec. 1931, Section IV, pages 27-35. *Oil & Gas Journal,* Vol. 30, Nov. 12, 1931, pages 44, 138, 140, 142-144; *Oil Weekly,* Vol. 63, Nov. 20, 1931, pages 20-24, 25, 28, 30, 32, 34.

Up to the present time there has been developed no uniform system whereby the magnitude of the economic losses arising from corrosion of production equipment can be determined. The general principles which must be applied in evaluating losses resulting from corrosion of production equipment are discussed under the headings of direct loss of material, cost of repairs, loss of production, indirect increase in production corrosion, and other sources of corrosion loss such as water-flooding of producing formations due to corrosion. The fundamental formula from which formulae are derived for each specific type of corrosion is

$$\text{Actual loss of material} = \text{Depreciated value at time of failure} - \text{Scrap recovering value}$$

VVK (4)

The Theory of Metallic Corrosion in the Light of Quantitative Measurements. Part IV. G. D. Bengough, A. R. Lee & F. Wormwell. *Proceedings Royal Society,* London, Vol. 131, May 1, 1931, pages 494-517.

The factors which prevent the steady progress of corrosion are first, formation of insoluble substances which give a local protection, and second non-uniform supply of oxygen. Test results with potassium chloride and potassium sulphate solutions are communicated. Ha (4)

Corrosion of Iron. C. W. Borgmann. *Bell Laboratories Record,* Vol. 10, Mar. 1932, pages 230-232.

Brief description of corrosion as an electrochemical process. The nature of the corrosion product is important. Products that have a gel structure can absorb moisture so that the moisture is not "free" to act as an electrolyte. Beyond a certain critical relative humidity, 40% at normal temperature in the case of iron rust, the moisture is free and rapid attack occurs. It is suggested that the corrosion product on a Cu-bearing steel is of such nature that it takes a higher humidity to produce free moisture. Ha+HWG (4)

The Effect of Oxygen on Gaseous Hydrogen Sulphide Corrosion of Tank Steel. John M. Devine, C. J. Wilhelm & Ludwig Schmidt. *Report of Investigations* 3160, United States Bureau of Mines, Feb. 1932, 19 pages.

O_2 is necessary to cause corrosion. The O/H_2S ratio in the gas is the prime consideration in predicting the magnitude of the corrosion; with a ratio of approximately 114, the maximum corrosion was obtained. Gases of relatively low H_2S content are more active in producing corrosion in the presence of a small amount of O_2 than are gases containing a relatively large amount of H_2S. However, approximately 0.025% (16 grains/100 ft.³) H_2S is the lower limit for producing severe corrosion at atmospheric pressure. Corrosion proceeds proportionally with time; scale is non-protective. AHE (4)

The Velocity of Corrosion from the Electrochemical Standpoint. U. R. Evans, L. C. Bannister & S. C. Britton. *Proceedings of the Royal Society,* London, Vol. A131, 1931, pages 355-375.

It is shown experimentally that, under conditions favorable for the complete tapping of electric currents flowing between the anodic and cathodic portions of corroding metals, the currents measured are equivalent to the corrosion produced. This is true both when the anodic and cathodic areas consist of different metals, and when the whole system consists of one metal, the anodic and cathodic areas being determined by differences in oxygen concentration. Owing to polarization, anodic and cathodic potentials tend to equality as the current flowing increases. This sets a limit to the corrosion rate which cannot be exceeded. There is an approximation to "equi-potential conditions" at fairly high concentrations, but anodic and cathodic potentials differ considerably in dilute solutions, where owing to the low specific conductivity, an appreciable residual e.m.f. is necessary to force even the small corrosion current through the circuit. Experimental results must be interpreted with caution, that is, when the primary skin has only occasional weak points (as on stainless steel), or if the anodic surface becomes covered with an undissolved layer of the anodic product. In most cases, the polarization which limits the corrosion rate occurs at the cathodic area, and is due to limitations of oxygen supply. Cathodic polarization curves, under controlled conditions of oxygen supply, end at high potentials in a horizontal part, indicating the law governing the ratio of anodic and cathodic areas. When corrosion starts at a weak point in the invisible film covering the sur.ace of a metal, the area undergoing attack extends (or contracts) until the cathodic current density on the part remaining unattacked is equal to the "protective value"; the current flowing under these conditions defines the rate of corrosion. The "protective value" is the current density which will cause any incipient attack on a weak point to lead to the precipitation of rust sealing the defect. This principle is used in the cathodic method of corrosion prevention, and several other methods of protection depend on the same principle. WAT (4)

The Corrosion of Metals II. (In English). W. PALMAER. Svenska Bokhandelscentralen A-B, Stockholm, 1931. Paper, 6½ x 9¼ inches, 198 pages. Price $3.85.

This volume includes rather detailed descriptions of experiments carried on by Palmaer's students in 1920-1924, which relate to special cases. Later research of a more general nature was recorded in Part I. Part III, not yet published, is to deal with the special theory of the corrosion of iron.

The title is somewhat misleading, as practically all the experiments deal with the rate of solution of metals in acid or other active solvents and not with corrosive conditions under which the metals would have a useful life. The author considers that all the experiments support the opinion that the primary factor in corrosion is the activity of local galvanic elements. The experiments deal with malleable iron, soft iron, electrolytic iron, zinc, aluminum, etc.

There is a table of contents, but no index. The high spots of the various investigations are not well summarized and those who happen to be interested in the rate of solution of metals by acids will have to read the whole book to follow the argument. H. W. Gillett(4)-B-

Temporary Rust Preventers. E. C. J. MARSH & E. MILLS. *Aircraft Engineering,* Vol. 4, Mar. 1932, pages 57-62.

The protection of partly finished and completed ferrous metal parts against corrosion has been studied. Mild steels still possess many advantages over non-corrodible metals. After reviewing the various protective methods, the merits of various classes of grease and oils are considered in detail giving the results of a large number of experimental tests with analytical and tabulated data and some selected photographs showing the relative efficacy of the media tried. Alkalies, waxes, soap greases, soluble oils, and non-drying varnishes are to be avoided as protective agents except in those rare cases where special conditions suggest their obvious adoption. Mineral oils and jellies usually command priority. Where lubrication is also a requirement; for components flowing through machine shops; for components, initially thoroughly clean, to be stored under reasonably good conditions; for slushing machinery during shut downs; and for all cases where good protection is required but contamination of non-ferrous parts is possible—mineral products should always be selected. Lanoline products yield the best protection. They should always be considered for finished iron and steel articles where excellent protective qualities are desired but where lubricity is not paramount. Where storage conditions are bad, linseed oil offers an alternative to lanoline in the coating of metal parts awaiting finishing processes. WAT (4)

Corrosion Tests Proving Value of Coatings. FLOYD SWINDELL. *Oil Weekly,* Vol. 61, May 22, 1931, pages 29-30.

The present investigation of protective coatings for pipe lines resulted from recommendations of the sub-committee on production and pipe line corrosion of the A. P. I. in the chairman's report in 1928. This report describes the second test opened for inspection. (4)

Evaluation of Laboratory and Service Corrosion Tests. (Bewertung von Laboratoriums- und Naturrostversuchen.) K. DAEVES. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde and the Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

Laboratory corrosion tests aim to determine, on a small scale and in a short time, the properties which are important for practical behavior. The general behavior of materials against corrosion attack cannot be established by laboratory tests, since the practical behavior depends less on the material than on the properties of the layers that are formed on the surface during corrosion. Corrosion tests in acids do not result in any conclusions as to the behavior in the atmosphere or in natural waters. Corrosion tests, therefore, should be performed under the actual conditions of application. GN (4)

The Nature and Causes of Dislodgment of Rust in Pipes. (Beschaffenheit und Ursachen der Rostablagerungen in Rohrleitungen.) K. BUNTE & P. STRUCK. *Das Gas- und Wasserfach,* Vol. 75, Jan. 1930, pages 87-89.

Tests were made to investigate the causes of rust which flaked off and clogged gas pipes. The oxygen content of the gas in the presence of condensed water has a direct effect on the kind of rust formed. Corrosion by steam is eliminated by drying the gas. When regeneration takes place, the addition of air must be very carefully regulated to prevent entrance of any oxygen into the gas. Washing the gas to remove impurities as well as hydrocarbons in the gas reduced the amount of rust. Gas cannot be purified satisfactorily as yet, but careful supervision of the purification system is very advantageous for lessening the formation of rust which flakes to clog the pipes. MAB (4)

Gas Plant Corrosion. B. G. DICK (Portland Gas & Coke Co.) *Gas Age-Record,* Vol. 68, Sept. 12, 1931, pages 381-386.

Part of Report of Committee on Plant Corrosion of the Pacific Coast Gas Association. So far there seems to be no concerted effort to reduce losses from corrosion in gas plants. Incomplete data that are now available cover only some of the more severe problems in corrosion; problems which the gas companies have from economic necessity been forced to combat scientifically. It is the opinion of the committee that a continuous comprehensive study of the causes and preventions of plant corrosion will be the logical procedure to follow if these corrosion losses are to be reduced to a minimum. Recent developments are discussed such as Cr and Cr-Ni steels, nitrided steels, the use of Al for oil storage tanks, paints and paint testing. Data on general corrosion problems and on accelerated paint testing is given in a report by the Central Arizona Light & Power Co. at Phoenix, Arizona. VVK (4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Physics and Metallography of Magnesium. (Beiträge zur Physik und Metallographie des Magnesiums.) E. SCHMIDT. *Die Metallbörse,* Vol. 21, June 13, 1931, page 1110; July 25, 1931, page 1398.

Reviews a paper before the Deutsche Bunsengesellschaft für angewandte physikalische Chemie, Vienna, 1931, discussing the anisotropy of physical properties, aging and deformation phenomena and formation of solid solutions. The second review refers to a more recent paper before the Kaiser Wilhelm Institut für Metallforschung, Berlin, 1931, which reports experiments on physicals, plasticity and metallographic investigations on binary solid solutions of Mg. EF (5a)

The Equilibrium Diagram of Iron-manganese-carbon Alloys of Commercial Purity. E. C. BAIN, E. S. DAVENPORT & W. S. N. WARING (Research Lab. of the U. S. Steel Corp.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 467, Feb. 1932, 24 pages.

Alloys of commercial purity prepared in a 250-lb. arc furnace were used. They contained as much as 1.5% C and 15% Mn. All forged without difficulty. The portion of the equilibrium diagram representing transformations in the solid state was determined from a microscopic examination of the alloys as quenched from various temperatures. X-ray methods were also used, but they served only to confirm the results of microscopic examination. The phases austenite, ferrite and carbide were found. Mn was considered as replacing some Fe in the carbide phase as the Mn content increased. The epsilon phase was not considered to be stable at any temperature. Few data are given, but the results are shown in sections of the 3-dimensional diagram. 14 references. JLG (5a)

A Metallographic Investigation of Native Silver. H. C. H. CARPENTER & M. S. FISHER. *Bulletin Institution of Mining & Metallurgy* No. 330, March 1932, 22 pages; No. 331, Apr. 1932, pages 1-25; *Metal Industry,* London, Vol. 40, Mar. 25, 1932, pages 344, 349.

The authors, investigating 21 specimens of native Ag and Ag ores from 14 localities, found that Ag can recrystallize at ordinary temperature but that when it does so the recrystallization is incomplete and the structure of the metal does not become homogeneous. Native Ag is deposited by aqueous solutions of meteoric or juvenile origin. Supergene Ag and Ag deposited by cool hypogene solutions may have an unaltered structure free from any trace of recrystallization, or a partly recrystallized structure, but not a coarse homogeneous structure like that produced by annealing the metal. A structure of the latter type is characteristic of native Ag that has been formed by highly-heated hypogene solutions at a temperature above the normal recrystallization temperature of Ag, about 200° C. Native Ag from most localities has been deposited by meteoric waters or by cool hypogene solutions. At Excelsior Prospect (N. Rhodesia), at Lake Superior and in the Cobalt district of Ontario Ag has been deposited by hot juvenile solutions at a temperature above 200°. Contains 30 excellent microphotographs. PRK+AHE (5a)

Equilibrium Relations in Aluminum-copper-magnesium and Aluminum-copper-magnesium Silicide Alloys. E. H. DIX, JR., G. F. SAGER & B. P. SAGER (Aluminum Research Laboratories). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 472, Feb. 1932, 13 pages.

The effect of 0.5% Mg on the solid solubility of Cu in Al was investigated by microscopic methods. This quantity of Mg slightly decreased the solubility of Cu at all temperatures. The small decrease in solubility would hardly account for the effects of Mg in strong Al alloys. The influence of Mg in these alloys may be due to the effect that it exerts on the degree of dispersion of the $CuAl_2$ or the precipitation rate. The effect of 1.3% Mg_2Si on the temperatures and concentrations at which $CuAl_2$ is precipitated was found to be negligible. In these alloys, however, a new phase containing Al-Cu-Mg-Si is formed. The line along which this compound is formed is somewhat over 100° C. above the line along which $CuAl_2$ is formed. 15 references. JLG (5a)

Multiple Systems with Iron, IV. The System Cr-C (and Fe-Cr-C). (Ueber Mehrstoffsysteme mit Eisen, IV. Das System Cr-C (and Fe-Cr-C). E. FRIEMANN, F. SAUERWALD & A. WINTRICH. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 203, Dec. 30, 1931, pages 64-74.

The equilibrium diagrams were determined and discussed; it is found that a stable and a metastable system co-exist. Carbides exist in several modifications, Cr_3C_2, Cr_7C_3, and Cr_4C; they differ by the degrees of hardness and can be distinguished by relief polish. The solubility of C in solid Cr is apparently smaller than 0.03%. 13 references. Ha (5a)

Equilibrium Relations in Aluminum-cobalt Alloys of High Purity. WILLIAM L. FINK & H. R. FRECHE (Aluminum Research Laboratories). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 473, Feb. 1932, 10 pages.

According to Gwyer, a eutectic is formed at the Al end of the diagram between Al and Co_3Al_{13}. Analyses of the compound obtained as a residue indicated that it corresponded to composition Co_2Al_9. The eutectic concentration appeared to be 1.45% Co as judged by microscopic examination, but extrapolation of freezing point data indicated that it was 1.0% Co. The solid solubility of Co in Al at just below the eutectic temperature was found to be less than 0.02%. The liquidus between the eutectic and the compound was determined by analyzing the liquor in equilibrium with Co_2Al_9 at various temperatures. The eutectic temperature was found to be 657° C. The diagram up to 8% Co is given. 11 references. JLG (5a)

Antifriction Alloys of Sn, Pb, Cu and Sb Rich in Tin. (Sur les alliages antifrictions Sn, Pb, Cu, Sb riches en étain.) M. FOURNIER. *Revue de Métallurgie,* Vol. 29, Feb. 1932, pages 101-107.

36 alloys containing a maximum of 12% Sb, 6% Pb and 6% Cu were studied microscopically and by hardness determination both in slowly cooled and chill cast state. Cu besides supplying a hard constituent Sn-Cu acts as a stabilizer permitting the formation of a homogenous alloy after a reasonably slow cooling. Under the microscope Sb can be estimated when higher than 8%, Cu fairly well but Pb not at all. JDG (5a)

Structure & X-Ray Analysis (5b)

A Precision Method of Measuring Small Changes of Lattice Spacings of Metal Single Crystals. RUDOLF C. HERGENROTHER. *Physics,* Vol. 2, Feb. 1932, pages 63-69.

A method of studying the progressive crystal lattice changes occurring in a series of alloys or mixed crystals is described. This method compares the Bragg angles of X-ray reflection from standard crystals with those of the crystal being studied. The important features of the method are simplicity and high accuracy (0.002%), which is attained without the use of an accurately calibrated angle scale. The theory of the method is discussed and two examples of experimental data which have been obtained are given. WAT (5b)

The Cathode Ray Effect Connected with X-ray-Spectroscopic Analysis. (Ueber den bei roentgenspektroskopischen Analyse auftretenden Kathoden-strahleneffekt.) M. ISHIBASHI. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 202, Dec. 24, 1931, pages 372-374.

The author describes the change which a composition of Ti oxide, Ba sulphate and Fe oxide undergoes when subjected to analysis by cathode rays. The intensity of certain lines is increased. A number of measurements on meteorites are described. Ha (5b)

Corrosion Structure, Corrosion Mechanism and the Tamman Resistance Limits. X-ray Examination of Gold Copper Single Crystals. (Korrosionsgefüge, Korrosionsmechanismus und die Tammann'schen Resistenzgrenzen. Röntgenographische Untersuchung an Gold-Kupfer-Einkristallen.) L. GRAF. *Metallwirtschaft,* Vol. 11, Feb. 5, 1932, pages 77-82; Feb. 12, 1932, pages 91-96.

Contains 14 references. Au-Cu alloys consisting of single crystals were etched with various reagents which attack Cu but not Au, and the surface of the alloys was then examined by means of X-rays to determine its composition and structure. The liberated Au atoms, which are not attacked by the reagents, combine to form a thin new layer on the surface of the alloy with the same crystallographic orientation as that of the Au-Cu single crystal. Strongly oxidizing reagents such as HNO_3, H_2CrO_4 and $HMnO_4$ produce a layer of pure Au without any intermediate zone. Weakly oxidizing reagents, alcoholic picric acid, sulphur compounds, such as $(NH_4)_xS$ and Na_2S, and gases at ordinary temperatures produce a Au rich alloy of variable Cu content. At elevated temperatures, above 200°C., where atomic diffusion takes place, gases produce a pure Au surface layer which gradually changes to the alloy structure. Aqua regia, which attacks both Cu and Au, produces a pure Au surface while KCN-H_2O_2 solution forms an alloy structure. The theory of the formation of the surface layer is discussed at length. There are 3 possible ways: directly, through the lattice forces, or indirectly, through diffusion or ionization. Under the action of strongly oxidizing reagents, including aqua regia, both Au and Cu atoms on the surface become ionized. The Au atoms leave their position in the lattice and exchange places with neutral Cu atoms, transferring their charges to the Cu atoms when they reenter the lattice, until a surface of pure Au is formed. Under the action of gases at ordinary temperatures and other solutions the Cu atoms only become ionized and are removed from the lattice. The exposed neutral Au atoms remaining in the lattice rearrange themselves due to their lattice forces. A small number of Cu atoms are trapped in the rearranged structure, forming a surface alloy rich in Au and with variable Cu content. During gas attack at elevated temperatures the mobility of atoms due to diffusion outweighs the lattice forces and no Cu atoms become trapped in the surface layer. This theory is used to explain the limits of resistance to chemical attack, described by Tamman. Reagents which form an Au rich surface alloy attack alloys containing up to 25 atomic % Au. Due to the uni-dimensional mobility of the atoms one Au atom is enough to block the attack on a whole chain of atoms. Strongly oxidizing reagents attack up to 50 atomic % Au alloys, as the ionized atoms have tri-dimensional mobility and it requires 2 Au atoms to prevent attack by the reagent. CEM (5b)

X-Ray Research in Metallurgical Science. (Röntgenforschung in der Metallkunde.) Vol. 10 of Ergebnisse der Exakten Naturwissenschaften. ULRICH DEHLINGER. Julius Springer Verlag, Berlin, 1931. Paper, 6 x 9½ inches, 386 pages. Price 37.60 RM.

This paper appearing in one of the annual volumes of a series relating to progress of science has also been published as a separate monograph. The author is well known for his investigations in the field of the structure of metals and alloys, especially as regards the theory of deformation. The subject matter is divided into two parts; the first, researches on states which are in thermodynamic equilibrium, including structures and properties of elementary metals, solid solutions, over-structures and eutectics, and intermetallic compounds; and second, states which are not in thermodynamic equilibrium, including intermediate states of metallic transformations, growth structures, corrosion and deformation mechanism, and recrystallization texture.

The material is presented, of course, in very condensed form but some of the topics are of particular value, inasmuch as they are little known in other books dealing with X-ray methods. Among these are the treatment of the total and free energies of transformations such as body-centered and face-centered cubic iron, over-structures—that curious alloy behavior indicated by the appearance of new lines in the diffraction patterns, structure of the properties of marcasite, aging of metals and alloys, and the mechanism of deformation such as has been presented in several papers by the author. The whole exposition stresses the theoretical side and thus the monograph forms a valuable addition to more detailed descriptive results in the field of metallurgy available in several textbooks. It is to be hoped that the author will bring the material up to date yearly or expand the topics here treated into a book. George L. Clark (5b)-B-

Experiments on the Emission and Absorption of Radiation by Metallic Silver. F. L. MOHLER. *Bureau of Standards Journal of Research,* Research Paper 421, Vol. 8, Mar. 1932, pages 357-364.

The emission spectrum of Ag bombarded by electrons is characterized by a high intensity from the visible to 3600 A. U., with a decrease to a very low value beyond 3200 A. U. The spectrum emitted by Ag bombarded by 100-volt electrons in high vacuum is similar to the emission of a Ag probe surface at a low positive potential in a caesium discharge. Probe emission spectra at different temperatures have been compared and a small effect found which may or may not be a pure temperature effect. The slope between 3600 A. U. and 3200 A. U. becomes slightly less with a shift toward longer wave length with increasing temperature. The absorption of a silvered quartz plate has been measured at temperatures between 20° and 490° K. There is a large increase in absorption with increasing temperature limited to the range 3350 to 2950 A. U. with a maximum effect at 3100 A. U. The effect is a decrease in slope of the violet edge of the selective transmission band with increasing temperature. The results are contrary to a theory proposed by Boeckner and the author. The observed change in emission is less and in absorption much greater than the predicted effect. WAT (5b)

An X-Ray Investigation of Some Copper-Aluminum Alloys. G. D. PRESTON (National Physical Laboratory). *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Nov. 1931, pages 980-993.

Gives results of an investigation dealing with that part of the Cu-Al system containing 31-50 atomic % Al. The lower limit coincides with the boundary of the γ phase. This investigation shows that the cubic γ phase has a homogeneity range extending from 31 to 35.5 atomic % Al. Above this, a hexagonal phase exists in the neighborhood of 43 atomic % Al and then by an orthorhombic phase which is probably CuAl. The hexagonal phase exists over an extended range of temperature and probably exists at room temperature. The orthorhombic exists at about 600° C. but probably undergoes transformation at room temperatures. Some general deductions tend to support the theory advanced by W. Rosenhain concerning the nature of intermetallic compounds. Rosenhain's theory is that neighboring phases in a constitutional diagram might arise from definite molecular groups of atoms held together by other atoms, the range of existence (in concentration) of the phase being supposed to be due to the possibility of replacing the binding atoms by atoms of either element while the "molecule" or group remained unchanged from phase to phase. RHP (5b)

Research on Primary Crystallization. (Beiträge zur Frage der Primärkristallisation.) F. RAPATZ. *Stahl und Eisen,* Vol. 52, Feb. 18, 1932, pages 171-172.

Discussion of Hensel, Tammann and Leitner's research studies on primary crystallization. Variables considered are composition of alloys, casting temperature, rate of casting, type of mold and mold preheating, with their separate effect on amount of primary, secondary, and tertiary crystallization zones, transcrystallization, and crystal size. 2 types of materials were stressed: (1) high Sn alloys, and (2) 3 to 4% Si steels. DTR (5b)

The Present Status of Possibilities of Diascopic X-Ray Tests. (Der gegenwartige Stand Röntgendiaskopischer Prüfungsmöglichkeiten.) H. REININGER. *Werkstattstechnik,* Vol. 25, May 1, 1931, pages 225-230.

The principle of translucency for X-rays are discussed and apparatus for this simplest method of X-ray testing in the shop described. A list of 30 references is added. Ha (5b)

New Calibration Method for Precise Determination of Lattice Constants of Poly-crystalline Material. (Neue Eichungsmethode zur Präzisionsbestimmung von Gitterkonstanten an polykristallinen Materialien.) F. REGLER. *Physikalische Zeitschrift,* Vol. 32, Sept. 1, 1931, pages 680-687.

Deviations from the true value of space lattice constants were noticed on polycrystalline material investigated by the Debye-Scherrer-Hull method. In spite of taking into account the Harding correction, increasing values of space lattice constants were measured with increasing reflection angles and with constant dimensions of the sample on one hand and a steady increase of the mean value of the space lattice-constants was obtained with increasing sizes of 2 g of the sample on the other hand. Therefore Regler set forth to quantitatively study the sources of trouble in order to eliminate errors in future measurements. The corrections which must be taken into account in addition to the Harding correction are graphically presented. The investigator employed an X-ray tube of 20 kv, 10^{-2} Amp, provided with an Fe anticathode and Lindemann window and used the K_α radiation of Fe. EF (5b)

X-Ray Crystal Analysis. G. CADOGAN ROTHERY. *Electrical Review,* Vol. 110, Jan. 8, 1932, page 48.

Review of a report issued by an X-Ray Committee under the chairmanship of Sir William Bragg, appointed by the Department of Scientific and Industrial Research. One of the problems investigated was the "spoiling" and recovery of W magnet steels. These steels show a serious drop in coercive force after heat treatment between 900° and 1000° C. but recover their magnetic quality after a brief reheating at 1250° C. Before hardening and magnetizing, W steel gives an X-ray pattern with lines of α-iron. After treating at 900° C., the pattern contains new lines due to formation of tungsten carbide, WC, and a mixed carbide of tungsten and iron, $Fe_4 W_2C$. The carbide lines disappear on reheating at 1250° C. If the steels are H_2O quenched at 850° C. or lower, after heating at 1250° C., the carbide lines will appear. Annealing at 1250°, 1150°, 1025° and 900° C. resulted in the appearance of the carbide lines at 1150°, the $Fe_4 W_2C$ lines increasing continuously as the temperature fell. The X-ray method has been applied to the study of electrolytic deposits of metals. Investigation showed distinct selective crystal orientation, the degree of orientation depending upon current density and the nature of the electrolyte. MS (5b)

The Intensities of Interferences Produced by Rapid Cathode Rays and a Suitable Apparatus for Demonstration Purposes. (Ueber die Intensitäten der Interferenzen von schnellen Kathodenstrahlen und Vorführung eines einfachen Interferenzapparates für Demonstrationszwecke.) F. KIRCHNER. *Physikalische Zeitschrift*, Vol. 32, Dec. 15, 1931, pages 969-971.

The utilization of X-rays for the investigation of crystal powders is compared with the application of cathode rays. Experiments on poly-crystalline material and single crystals are discussed and a simple interference apparatus is demonstrated at the 7th Deutscher Physiker und Mathematikertag, Bad Elster, Sept. 1931. EF (5b)

An X-ray Study of the Nature of Solid Solutions. ROBERT T. PHELPS & WHEELER P. DAVEY (Pennsylvania State College). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 443, Feb. 1932, 14 pages.

Ag-rich alloys containing as much as 9% Al were prepared from metals of high purity. Their lattice dimensions were determined by X-ray diffraction methods, where the patterns were compared with NaCl. Densities were obtained by weighing in air and alcohol. The samples were heat treated in order to promote homogeneity. From the diffraction patterns, it was evident that about 5.4% Al was soluble in solid Ag. Further additions of Al gave aggregates of Ag_3Al. The densities as calculated from lattice parameters and as determined by weighing were the same for pure Ag, but as Al was added the density determined by weighing was less than the calculated value. The difference between the 2 values increased with increasing Al. From considerations of the possible arrangements of atoms in crystals, it was concluded that the Al atoms could not be replacing the Ag atoms, but the Al in solution was chemically combined with the Ag. In this case, there are units of structure of lower density, which are not sufficiently abundant to form a diffraction pattern. This picture was not found to be inconsistent with any of the known properties of solid solutions. 25 references. JLG (5b)

An X-Ray Determination of Crystal Orientation in Nickel, Copper and Aluminum, Produced by Cold Rolling. C. B. HOLLABAUGH & W. P. DAVEY. *Physical Review*, Vol. 37, June 15, 1931, pages 1697-1698.

High purity Ni, Cu and Al, free from all preferred orientation, were cold rolled in such a way as to produce no appreciable temperature rise and the orientations were determined after each pass. Ni and Cu showed identical orientations both as to limits of ranges of preferred orientations and mean positions. The number of passes through the rolls determines the probability that a crystal fragment will be within the preferred range. Al shows a related preferred orientation, but with widely different angular limits which depend on the number of passes through the rolls. This work shows, contrary to the accepted belief, that except for Cu and Ni, the common face-centered cubic metals show differences in preferred orientation, both with respect to the limits of preferred range and with respect to the mean position of orientation. WAT (5b)

On the Question of Slip in Crystalline Structure during Rolling. S. T. KONOBEEVSKY. *Zhurnal Prikladnoi Fiziki* (*Journal of Applied Physics*), Vol. 4, No. 3, 1927, pages 1-8.

Al is found to possess 2 different types of structure, depending on the degree of working. One is obtained as the result of light rolling and possesses an axis in the plane of a rhombic dodecahedron, between the directions (111) and (211), somewhat nearer to the latter. The other, produced by heavy rolling, has an axis the indices of which are (110), while the upper surface of the plate is in the plane parallel to the cube (100). No transitional stages between the 2 types can be detected, although the presence of both may be observed quite clearly on a rolled plate. An explanation of the formation of the 2 types is given. WHB (5b)

A Heating Arrangement for X-Ray Samples (Ueber eine Heizvorrichtung für Röntgenpräparate). G. WASSERMANN. *Metallwirtschaft*, Vol. 10, Dec. 4, 1931, pages 922-923.

Disadvantages of other methods are overcome by heating the sample in the stream of an inert gas which has been heated outside of the X-ray apparatus. The sample is mounted vertically in a small porcelain tube and the gas flows from a cylinder through a furnace and then through a short movable glass tube at right angles to the sample. On the opposite side of the sample, another glass tube of larger diameter is mounted through which the gas is removed by suction. The distance of the 2 glass tubes from the sample can be closely adjusted. The thermocouple for determining the temperature of the sample is placed in the exit tube. Advantages of this method are accessibility of the sample by moving the glass tubes, adjustment of the temperature by varying the gas pressure and accuracy of temperature measurement. CEM (5b)

The Chemistry of Alloys. (Zur Chemie der Legierungen). A. WESTGREN. *Zeitschrift für angewandte Chemie*, Vol. 45, Jan. 9, 1932, pages 33-40.

After discussing the variability of the composition of alloy phases, the author deals with the determination of the formulas of metallic phases from their atomic arrangements, quoting as examples measurements which have resulted in arriving at the compositions of the β-phase of the Cu-Zn system, of $FeSi_2$ and other intermetallic compounds. A discussion follows of the similarity of the powder photograms of such intermetallic compounds as Ag_3Al and Cu_5Si to that of β-Mn. The author concludes that consideration of the results presented leads inevitably to the view that a new definition for what may be termed the ideal intermetallic compound must be formulated. Attention is then directed to the recurrence of similar structural types in the alloys of Cu, Ag, and Au, reference being made to Hume-Rothery's observations regarding the relationship between the valence-electrons and the atoms in certain phases of these systems. Regularities in the structures of the alloys of the transition elements are made the subject of comment, the paper in closing emphasizing the value of X-rays in deciding the character of the various alloys which are met with. OWE (5b)

Graphical and Mechanical Evaluation of Debye-Scherrer Photograms of Cubic, Tetragonal, Hexagonal or Orthorhombic Symmetry, including the following Examples: WC, PdF_2 and $HgCl_2$. (Graphische bezw. maschinelle Auswertung von Debye-Scherrer Diagrammen kubischer, tetragonaler, hexagonaler und rhombischer Symetrie mit Anwendungsbeispielen: WC, PdF_2 und $HgCl_2$.) E. Ebert (Technische Hochschule Breslau) *Zeitschrift für Kristallographie,* Vol. 78, July 1931, pages 489-495.

A simple evaluation method of Debye-Scherrer photograms is mathematically derived which, in contrast with the Hull-Davey charts, permits the use of straight lines due to a decomposition of the quadratic forms. A possibility of a mechanical evaluation method of Debye-Scherrer photograms is indicated and the description of the completed apparatus is announced. The utilization of the graphical evaluation method is demonstrated by means of the following representative compounds: WC (hexagonal), PdF_2 (tetragonal) and $HgCl_2$ (ortho-rhombic). EF (5b)

Equilibrium Relations in Aluminum-zinc Alloys of High Purity. William L. Fink & Kent R. Van Horn (Aluminum Research Laboratories). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 474, Feb. 1932, 11 pages.

Hardness, conductivity measurements and microscopic examination were not found to be satisfactory for locating the solid solubility limit of Zn in Al. This limit was therefore determined by use of X-rays, where powder patterns were obtained from filings at temperatures up to 250 °C. The solubility limit was determined from the presence of diffraction lines from the Zn phase, a correction being applied for the amount of Zn that would just fail to produce visible lines (0.5%). The solubility of Zn in Al was found to be:

Temperature °C	Zn %
25	2.7
100	5.2
150	7.4
200	9.4
250	13.4

The Structure of Rolled Zinc and Magnesium (Die Walztextur von Zink und Magnesium). V. Cagliotti & G. Sachs. *Metallwirtschaft,* Vol. 11, Jan. 1, 1932, pages 1-4.

Contains 20 references. X-ray diffraction patterns were obtained for several samples of hot rolled sheet Zn and Mg, with the X-rays impinging in 10 different directions. The Zn photograms have the same appearance as those previously published in the literature. The pole figures show preferred orientation not only for the base but also for the pyramid. The Mg photograms differ according to the initial rolling temperature. The base ring is blackened near the equator in every case but the other diffraction rings of sheets rolled at 300° C. and under are blackened evenly. Rolled at 550° C., they show 6 sharp concentrations of intensity. The pole figures show distinctly outlined areas of concentration. The only difference between the structure of Zn and Mg is that in Zn the strongest concentration of the base surface is not in the rolling plane but at an angle of about 30° to the rolling direction, forwards and backwards, and about 25° to the rolling plane. The samples were also annealed at 200°, 400° and 600° C. The recrystallization structure is practically the same as the rolled structure. CEM (5b)

Report of the Abstract Committee. Abstracting Schemes for X-Ray Determinations of (I) Single Substances and (II) Series of Substances. (English) J. D. Bernal, P. P. Ewald & Ch. Mauguin. *Zeitschrift für Kristallographie,* Vol. 79, July 1931, pages 495-530.

The account of the abstract form proposed by a special committee appointed to consider the preparation of a standard sheet for abstracting structural papers. EF (5b)

A Simple Ray- and High-Voltage-Proof Apparatus for Structure Pictures. (Ein einfacher strahlen-und hochspannungssicherer Apparat für Strukturaufnahmen.) A. Bouwers & W. Busse. *Zeitschrift für Kristallographie,* Vol. 177, May/June 1931, pages 507-514.

The X-ray tube is grounded in the center so that the preparation can be placed closer to the focus of the tube on account of the reduced voltage, and the time of exposure is greatly shortened. Ha (5b)

Precision Determination of the Dimensions of Crystal Space Lattices. (Präzisionsbestimmung der Dimensionen von Kristallgittern.) N. H. Kolkmeijer & A. L. Th. Moesveld (Van't Hoff Laboratory, Utrecht) *Zeitschrift für Kristallographie,* Vol. 80, Sept. 1931, pages 63-90.

Directing the attention to the various sources of errors involved in space lattice determinations by the use of the powder method, the authors set forth to convert this X-ray method into a precision measurement. The improvements on the Debye--Scherrer camera and the subsequent evaluation refer to (a) the insertion of the film, (b) centering of the sample, (c) the photographic operation, (d) outmeasuring technique, (I) evaluation, (II) checking, (III) correction for shrinkage (IV) corrections for the thickness of the sample, divergency of the beam and eccentricity of the testing sample (V) further calculations. The second part of the paper demonstrates the advantageous utilization of the writer's suggestions based on an investigation on rock salt, showing that the improvements lead to a "precision method of determination." EF (5b)

A Preliminary Report on a New Method of X-Ray Powder Diffraction. T. M. Hahn. *Physical Review,* Vol. 37, 1931, page 475.

A preliminary report on a method employing the use of a conical beam of X-rays incident upon powdered crystals arranged in a circular form about the central axis of the cone, normal to the axis. All rays diffracted through an angle θ will be brought together at a common point on the axis of the cone. A photographic film along this axis receives the record of the diffraction pattern, from which the spacing of the planes of the crystal may be determined. Advantages of this method are reduced time of exposure and an increased separation of diffraction spots. WAT (5b)

Radiation from Probe Surfaces Bombarded by Electrons. F. L. Mohler & C. Boeckner. *Bureau of Standards Journal of Research,* Vol. 7, Oct. 1931, pages 751-764.

Metals in the form of small probe surfaces are held at a positive potential in the highly ionized region of a discharge (commonly a cæsium discharge) and under intense electron bombardment emit radiation. Photographic spectro-photometric measurements are made. Radiations at 7 volts from W, Al, Be, Au alloyed with Cs, Th, and Pt are similar in intensity and intensity distribution. The spectral energy distribution on a wave-length scale is nearly constant between 6,400 and 2,400 A. U. with a radiation flux of about 20 ergs for a wave-length range of 1μ and for a current density of 1 ampere/cm². J (λ) for Cu has a pronounced increase in the red and for silver a tenfold increase between 3,200 and 3,600 A. U. Above 6 volts this intensity distribution remains the same while with lower voltages it drops almost linearly to zero with increasing ν. The threshold value of ν agrees with the relation $h\nu = e(V+W)$ where W is 1.45 volts for tungsten and about 2 volts for Cu, Ag, and Al. The voltage variation of intensity is different for each metal. The intensity and intensity distribution of tungsten and silver radiation in a helium discharge are similar to values obtained in cæsium vapor. The equal energy spectrum common to all metals is probably analogous to continuous X-rays. The selective radiation of silver and copper may correspond to characteristic X radiation. The high-frequency edge of the silver emission band has the shape of a Fermi distribution of electrons at 370° C., suggesting that the emission process involves the ionization of an underlying level and the fall of a conduction electron into that level. Theoretical Studies on the Structure of Twins. (Strukturtheoretische Studien über Zwillinge.) G. Aminoff & B. Broome (States Museum of Stockholm). *Zeitschrift für Kristallographie,* Vol. 80, Nov. 1931, pages 355-376.

The theoretical discussion pertains to ZnS, C (diamond), Au and PbS. EF (5b)

The Nature of Electron Movements in Crystals and Its Bearing on the Electrical Properties of Solids. (Über die Natur der Elektronenbewegung in Kristallen und ihre Bedeutung für das elektrische Verhalten der festen Körper.) Lothar Nordheim. *Metallwirtschaft,* Vol. 11, Feb. 26, 1932, pages 121-124; Mar. 4, pages 135-138.

Contains 9 references. A theoretical discussion on the relationship between the atomic structure and the difference between conductors, semi-conductors and insulators, deflection of electrons, X-ray absorption patterns and the Hall effect. For details the original article must be read. CEM (5b)

Space Lattice Constants for 1931. (Gitterkonstanten 1931). M. C. Neuburger. *Zeitschrift für Kristallographie,* Vol. 80, Sept. 1931, pages 103-131.

In a dozen tables Neuburger compiles the most ascertained data on the length of unit cell of elements, their crystal structure, atomic weight density (determined by X-rays) atomic radius, atomic space and atomic volume. 65 references. EF (5b)

Structure of Cold-drawn Tubing. John T. Norton & R. E. Hiller (Mass. Inst. of Technology.). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 448, Feb. 1932, 14 pages.

The orientation produced in metals by various types of cold work is discussed. Orientation in low-carbon steel tubing was studied by the monochromatic pin-hole method. Orientations in steel sheet and wire were also determined as checks on the study of tubing. Conforming other investigators, a [110] direction tends to come in alignment with the axis of the wire, while in sheet a (110) plane becomes parallel to the direction of rolling and at right angles to the plane of the sheet with a second set of (110) planes at right angles both to the direction of rolling and the plane of the sheet. In tubing, the structure was intermediate between that of sheet and wire. With a reduction in wall thickness alone the structure conformed to that of sheet, while with equal reductions of wall and diameter the structure was that observed in wire. Samples worked by several methods to the same reduction gave similar structures, thereby indicating that orientation of the crystals was a function of the relative reductions and not of the manner of working. It was concluded that in processes which allow a greater reduction without annealing or produce a more ductile material, such as rolling on some of the 4-high mills, produce similar structures in the metal and that the better properties can be due only to the improved surface. 2 references. The Trend of X-Ray Analysis in Metallurgy. L. Pickup. *Metallurgia,* Vol. 5, Mar. 1932, pages 177-179.

Discussion of crystal structure of metals and alloys as determined by X-ray diffraction. Gives methods of analysis and discusses recent results. JLG (5b)

X-Rays in Engineering Practice. V. E. Pullin. *Proceedings Institution Mechanical Engineers,* Vol. 2, Pt. 2, Dec. 1930, pages 1133-1157.

With discussion. The application of radiology in the examination of castings, forgings, structures, etc., to show flaws and lack of homogeneity is surveyed. Many examples are shown in photographs. The methods of producing X-rays; the power of penetration and absorption in materials are explained. Ha (5b)

Atomic Influential Spheres with Tetraeder-Symmetry as a Common Element in Structure of All Crystal Space Lattices. (Atomare Wirkungsbereiche mit Tetraeder-symetrie als gemeinsames Bauelement der sämtlichen Kristallgitter.) R. Reinicke. *Zeitschrift für Kristallographie,* Vol. 78, June 1931, pages 334-362.

The author figured out a new classification of crystal systems based on tetraeder-symmetry and defines the following groups: Mg type: Be, Mg, Zn, Cd. Wurzit type: BeO, MgTe, ZnO, CdS, CdSe. Cu type (face centered cubic lattice): Cu, Ag, Au, Ca, Al, Ce-α, Th, Pb, Fe-γ, Co-α, Ni, Rh, Pd, Ir, Pt. EF (5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Tests of Cast Iron (Les essais des fontes, considérations basées sur les résultats de différents essais et particulierement sur les essais faits en Tchécoslovaquie). M. F. Pisek. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 751-761, 13 figures; *Revue de Métallurgie,* Vol. 28, May 1931, pages 280-281.

Comparison on 12 irons, of different transverse and tensile test bars and of various shear tests. Best agreement was found in shear tests, next in tensile tests and the poorest in transverse. Frequency curves are plotted. (See discussion below). HWG+JDG (6)

Control of Cast Iron by the Shear Test (Du controle des moulages au moyen de l'essai au cisaillement). *Commission Scientifique de l'Association Technique de Fonderie de Belgique, Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 725-727; *Revue de Métallurgie,* Vol. 28, May 1931, pages 276-279.

A coöperative study of the behavior of small shear test specimens cut from iron castings of various cross sections in comparison with that of specimens cut from projecting coupons. The results were very erratic. The committee states that the results are interesting, but that while shear tests may sometimes come in as an acceptance test, it will have to have more study before it would serve for that purpose. (See discussion below.) HWG+JDG (6)

New Machine for Testing Small Cast Iron Specimens in Bending in Shear, and for Hardness (Nouvelle machine pour les essais des fontes sur petites eprouvettes (flexion-cisaillement-dureté). H. Thyssen & J. Bourdouxhe. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 729-733. 7 figures; *Revue de Métallurgie,* Vol. 28, May 1931, page 281.

One machine is provided with attachments for the tests named. The distance between supports in the transverse test is only 50 mm. (2"). The article is purely a description of the machine and does not deal with the relative results of tests on large and small specimens. (See discussion below). JDG+HWG (6)

Mechanical Tests of Cast Iron (Contribution aux recherches sur les essais méchaniques des fontes). H. Thyssen. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 735-740; *Revue de Métallurgie,* Vol. 28, May 1931, page 280.

Co-operative tests are recorded, comparing large and small transverse test bars, various shear tests, hardness and impact tests on a series of irons. An attempt was made to correlate the results with the compositions of the irons. No condemnation of any type of test nor conclusion that any one failed to give information was considered to be justified. The effect of Si and Mn on mechanical properties is overshadowed by the effect of the combined and graphite carbon. (See discussion below). HWG+JDG (6)

A Punching Shear Test for Control of Iron Castings (L'essai de cisaillement par poinconnage appliqué au controle des moulages de fonte). A. Deleuse. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 741-749; *Revue de Métallurgie,* Vol. 28, May 1931, page 280.

A slice of cast iron 3 mm. (0.12 in.) thick is put in a punch and die operated on a testing machine (details of punch and die size not stated) and the force required to shear out a disk measured. Results of this test are compared with those of tensile, transverse, and Fremont shear tests on 9 different alloy cast irons. The punching test was about as consistent as any other test. (See discussion below.) HWG+JDG (6)

Discussion—Methods of Testing Cast Iron (La méthode d'essais des fontes). *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 765-772.

Discussion dealt chiefly with the shear test. Several reported satisfactory experience with it while others thought it gave no useful information, and doubted whether it measured any important engineering property. There appeared to be general agreement that the details of any shear test should be precisely defined and standardized and that, while the utility of the test in its present stage of development was not yet established, the test deserved much further attention. HWG (6)

A Simple Hardness Tester (Ein einfacher Härteprüfer). Huetter. *Oberflächentechnik,* Vol. 9, Jan. 5, 1932, pages 2-3.

The instrument tests the hardness of a galvanic deposit by a scratch with a glass-hard steel point or diamond point under which the sample is pulled along. The point is pressed against the sample with 50 g., 100 g. or more according to the material. The width of the scratch is determined in 1/1000 mm. and serves as measure for the hardness. Although very simple, the instrument gives consistent results, for instance, for the same pressure it was measured on

rolled lead	144 µ
rolled tin	76
duralumin, hard	56
copper sheet, hard	48
hard rolled brass	36
nickel sheet	34

The hardening effect of Co in Ni deposits could be easily measured, the value of 34 went down to 20 at 75% Ni and remained constant to 100% Co. Ha (6)

The Measurement of Large Brinell Impressions in Steel Rails. H. H. Morgan & J. R. Mooney. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 118-128.

Includes discussion. See abstract of preprint. *Metals & Alloys,* Vol. 2, Nov. 1931, page 255. HWG (6)

A Contribution to the Studies of Methods for the Control of Foundry Products. Pierre Nicolau. *Transactions & Bulletin American Foundrymen's Association,* Vol. 5, Jan. 1932, pages 661-717.

A short history of the development of testing methods used in the past as well as those common today is given. The French have and still favor the Fremont shear test for determining heterogeneity and properties of castings, and Nicolau lends considerable support to the Fremont test through illustrations. A bibliography of 66 references to French contributions to the study of testing methods of cast iron concludes the paper. CHL (6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A.S.T.M. Research Committee on Fatigue of Metals.

Fatigue Testing of Wire. S. M. SHELTON. *Proceedings American Society for Testing Materials,* Vol. 31, Part 2, 1931, pages 204-220.

The preparation of specimens for endurance testing is costly. It is difficult to machine and test specimens of small diameter. Local stresses at the grips cause fracture there when a short specimen of un-reduced section is tested. To avoid these difficulties in the testing of 0.19" diameter wire, the bearings of a R. R. Moore endurance machine were separated to take specimens 66 in. long. Such a long rotating beam has a high deflection, and the bearings are mounted so they assume the proper angle. The weight of the specimen itself provides added stress in the middle of the span of about 6,000 lbs./in.² above that imposed by the loading weights. Over a 24" span the decrease in stress from the maximum is so small as to involve less error than do the measurements of diameter. Breaks more than 12" away from the center were disregarded, but 90% of the breaks were in that region, the added stress in the middle of the span leading to fracture there rather than at the collets. Special spring collets used for holding the wire are shown. A photograph of the apparatus is shown in Fig. 8, page 74, of the February, 1931, Vol. 2, No. 2, issue of *Metals & Alloys.* The mathematics of the stress calculations are given, as are the precautions taken to avoid resonant vibrations by proper choice of speed. Tests were carried out at 2000 r.p.m. on galvanized heat-treated wire, at 1900 r.p.m. on the same with zinc coating removed, and at 1700 r.p.m. for low carbon wire. Tests were carried to 10 million cycles unbroken. The data follow:

Material	Tensile Strength lbs./in²	Fatigue Limit lbs./in²	Fatigue Ratio
0.77% C wire quenched, tempered and galvanized	215000-230000	50000	.22
Same with coating stripped in HCl-$SbCl_3$	226000-230000	60000	.26
0.13% C steel wire not galvanized. The galvanized coating has a deleterious effect	69000	46000	.66

Tests on short specimens of the galvanized high carbon wire with ends swaged so as to prevent breaks at the ends which were threaded into special holders, also gave 50,000 fatigue limit. Machined short specimens reduced to 0.15" diameter at the breaking section of the high carbon steel gave an endurance limit over 100,000, i.e., the endurance ratio was .44. Similar specimens of the low carbon wire gave 56000 and endurance ratio of .81. This high endurance ratio is not explained. If "69,000 tensile" is a misprint for 96,000, the high endurance ratios on the low carbon steel would become more normal. The method of testing should be applicable to tubes and pipes. Includes discussion in which Peterson illustrates a method of preparing a cantilever fatigue specimen by boring it out with a parabolic-nosed tool so that the outside of the specimen need not be machined down, yet it will not break at the grip. H. F. Moore comments on the fact that since a slight change in range of partially reversed stress does not materially affect the endurance limit, small vibrations of an endurance specimen do not necessarily affect the result. HWG (6f)

Resistance to Alternating Forces and its Determination by Means of Hardness Testing Machines. (La Résistance aux Efforts A Iternés et sa Détermination à l'aide des Machine d'essais de Durée). *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Sept. 1931, pages 465-473.

A description of 3 new testing machines for fatigue determination. 1. Rotational alternation fatigue machine, in which the usual load applied by weights is replaced by a graduated beam on which a uniform load slides to give the desired total load on the specimens. This device reduces the space required by the weights as used in the old type machines. 2. Alternating torsion machine. 3. Tension-compression along longitudinal section of the specimen by means of electromagnets and spring principles. GTM (6f)

The Fatigue of Metals. H. F. MOORE. *International Congress Testing Materials, Amsterdam,* 1927, Part 1, page 297.

Most engineering formulas for the strength of materials were developed by civil and not mechanical engineers and are accurate only for static stresses of large structural members. Experience with axles and Wohler's rotating beam tests showed that failures might take place under alternating stresses at lower loads than called for by the accepted engineering formulas. The concept of a perfect elastic limit as a stress below which Hooke's law holds and repeated loadings are harmless depended on the postulate that material is continuous and homogeneous. Metallography has shown that this postulate is not true, except statistically on a large scale. Basquin in 1910 showed that the fatigue tests then reported did not indicate a definite endurance limit for materials. Later, more extensive endurance testing resulted in re-establishing the existence of a limit of stress below which a metal will withstand an indefinite number of reversals without fracture. There is a fairly good correlation between the endurance limit and tensile strength; in ferrous metals the former is about half the latter. Fatigue failure, as studied with the microscope, seems to be the spreading of localized fracture, rather than merely a slip. Irregularities in stress distribution weaken metal in fatigue, but not as much as the mathematical theory of elasticity would predict. Slip under repeated stress may occur without the development of a fatigue crack. The exact cause of the origin of a fatigue crack is not known but it is not known to occur without slip. Clean metal, smooth surfaces and avoiding sudden changes in section will improve fatigue strength. Rosenhain, in discussion, stated that fatigue failure has been known to occur without slip; failure in fatigue occurs by the exhaustion of ductility as in tension, but at a lower stress because the slip is in both directions. ELECTRO-CHEMISTRY (7)

Electroplating (7a)

The Influence of Acidity of the Electrolyte on the Structure and Hardness of Electrodeposited Nickel. D. J. MACNAUGHTAN & R. A. F. HAMMOND. *Transactions Faraday Society,* Vol. 27, Oct. 1931, pages 633-648.

Paper, accompanied by 3 tables and 7 diagrams, in which a description is given of an attempt to obtain further data concerning the influence of the conditions of deposition on the structure and hardness of electro-deposited Ni. The solutions used were typical of those used in commercial practice. Deposition was carried out at a constant temperature of 35 ± 0.5° C. and at a constant current density of 11 amps./ft.². The Brinell hardness of the deposits was determined and their microstructure examined. The results show that the acidity of the solution exerts a very marked influence upon the hardness and structure of the deposit, low acidity favoring the formation of hard deposits having a finely crystalline structure. It was found in each solution examined there was a critical pH above which a rapid rise in hardness with pH took place. It is thus possible by suitably adjusting the pH of such solutions as are described, to obtain hard or soft deposits. Confirmation is obtained of the previously published conclusion that for the production of hard deposits a nickel-sulphate solution buffered with ammonium salts is the most suitable. For the production of soft deposits solutions containing boric acid and sodium fluoride with boric acid, respectively, appear to be more suitable. OWE (7a)

Electroplating Aluminum on Production Basis Practicable with Process Control. W. S. MCARDLE (Aluminum Co. of America) *Automotive Industries,* Vol. 66, Jan. 16, 1932, pages 98-99, 110.

Technique developed by Harold K. Work built on improvement in surface preparation methods, including cleaning, activation, and roughening. Degree of success attained in an electroplated Al job depends on 2 factors: (1) metal surface must be properly cleaned prior to etching; (2) most important of all, etching must be deep enough to provide adequate anchorage for the plating. This etching is accomplished with special reagents, depending upon purity of Al. Three common etching solutions are: high metal dip, low metal dip, and acid dip. The acid dip is 1 (HF): 3 (HNO_3). DTR (7a)

Throwing Power of Plating Solutions with Particular Reference to Certain Zinc Plating Solutions. B. K. BRAUND. *Transactions Faraday Society,* Vol. 27, Oct. 1931, pages 661-674.

An article, accompanied by 3 diagrams and 5 tables, deals with work undertaken as part of a general investigation of the electrodeposition of metals upon Al and Al alloys. For determining throwing power, Braund used the method devised by Hering and Blum. 3 different plating solutions were used in these experiments. Conclusions regarding the points that should be observed in using the Hering and Blum apparatus are given. OWE (7a)

Chromium-Plating of Paper-Mill Rolls. R. E. CLEVELAND, *Paper Mill & Wood Pulp News,* Vol. 54, Jan. 24, 1931, pages 14-15.

A brief discussion of the advantages of Cr-plating paper-mill rolls to increase their life by its hardness and resistance to corrosion. WHB (7a)

The Electrochemical Behavior of Platinum in Hydrochloric Solution. (Ueber das elektrochemische Verhalten des Platins in salzsaurer Lösung.) G. GRUBE & H. REINHARDT. *Zeitschrift für Elektrochemie,* Vol. 37, June 1931, pages 307-320, *Siebert Festschrift,* 1931, pages 108-120.

Pt is dissolved anodically in concentrated, hot HCl. Electrodeposited Pt is more readily soluble than rolled Pt. When it is deposited at the cathode strong polarization takes place due probably to formation of a film, and generation of H. A strongly adhering Pt deposit can be obtained from a solution of 0.1 m.H_2PtCl_6 in 5N Hcl at 60° C. and a current density of 1 to 2 amp./dm.². Ha+HWG (7a)

Nickel Plating Practice Abroad. W. T. GRIFFITHS. *Electrical Times,* Vol. 81, Feb. 4, 1932, pages 147-149.

A review of the methods employed in the United States and in continental plants; especially in the factories of Automobil Renault, Paris; plant of Société de Radiateurs Chassez, Paris; Citroen; and Opelwerke, Germany. WR (7a)

The Electrolytic Dissolution and Deposition of Metals. (Ueber das elektrolytische Auflösen und Abscheiden von Metallen.) J. HOEKSTRA. *Recueil Travaux Chimiques des Pays-Bas,* Vol. 50, Mar. 15, 1931, pages 339-342.

Under ordinary conditions of electrolysis the voltage—current density curves for the deposition of metals usually have a logarithmic form but if the electrodes are continuously rubbed, the curve becomes a straight line. Photomicrographic examination of metal deposits during the progress of electrodeposition shows that the metal is deposited in layers of about 1000 atoms in thickness; the surfaces of the crystals become covered with "active lines," which vary in shape and number with the conditions of deposition, and which spread over the surface of the crystals with increasing time of deposition. Fe, Ni, and Co deposits do not follow these rules, but are built up of relatively thick layers of nodular shape. Ha (7a)

Investigation of "Chromprotekt." (Untersuchungen über das Chromprotekt.) B. RASSOW & L. WOLF. *Chemiker-Zeitung,* Vol. 55, Jan. 28, 1931, pages 73-76.

Chromprotekt is a commercial product supposed to prevent poisonous Cr fumes from escaping from the Cr plating solution when the solution is covered with it. The claims made for it by the manufacturers were investigated. It is a refined petroleum with the addition of some ester to reduce its odor. The plated parts lose their brightness when removed from the tank, necessitating polishing. Chromprotekt produces some objectionable fumes itself and the gases escaping from the tank are not free from Cr. The idea of using a petroleum product was not an original idea of the manufacturers. CEM (7a)

Electroplating and Polishing Equipment and Supplies. LOUIS M. HAGUE. *Metal Industry,* N. Y., Vol. 29, Nov. 1931, page 486.

Recent growth of the industry of the polishing and plating of metals calls for men of special qualifications. Such qualifications are discussed. PRK (7a)

Bath and Pickling Containers in Electroplating. (Bad-und Beizgefässe in der Galvanotechnik.) H. KURREIN. *Metallwarenindustrie und Galvanotechnik*, Vol. 29, Mar. 1931, pages 213-215.

Tanks made of an artificial phenol-formaldehyde resin to which asbestos is added, are recommended for acid Cu and Zn baths, Ni baths, phenol-sulphonic acid, Sn and Pb baths, tartaric and acetic acid baths and neutral liquids. This material will stand rapid changes of temperature and has a low heat and electric conductivity, and light weight. Ha (7a)

Electrometallurgy (7b)

Effect of Cobalt on Technical Zinc Electrolysis. (Einfluss von Kobalt auf die technische Zinkelektrolyse.) P. RÖNTGEN & R. BUCHKREMER. *Metallwirtschaft*, Vol. 10, Dec. 25, 1931, pages 963-967.

Contains 7 references. The effect of Co additions on the yield of Zn under varying working conditions was determined in a series of tests. In colloid free electrolytes Co reduces the yield considerably. 10 mg./L. Co at 20 amp./dm.^{2}, room temperature, and 100 g. H_2SO_4/L. is harmless. But with about 100 mg./L. Co and 100 or 200 g. H_2SO_4/L. the yield is very low unless very high current densities are used. The addition of a proper amount of colloid such as gelatin overcomes the effect of Co entirely, especially when the temperature is raised. For instance the yield in a solution containing 100 g. H_2SO_4, 0.5 g. gelatin and 100 mg. Co/L. at 60° C. was 93%, while in the same solution without Co and gelatin at 20° it was only 83%. With 300 g. H_2SO_4/L. less than 10 mg. Co is permissible, with 200 g./L. H_2SO_4 up to 100 mg. Co, and with 100 g./L. H_2SO_4 up to 500 mg. Co, through addition of gelatin and increased temperature. With higher current than 20 amp./dm.^{2} more Co is permissible. Photographs of the cathodes are included showing the effect of Co and gelatin additions on the smoothness and corrosion of the deposit. CEM (7b)

The Production of Zinc by Electrolysis. I. HARRY HEY. *Chemical Engineering & Mining Review*, Vol. 24, Feb. 5, 1932, page 164-169.

Present practice in Zn production is of cyclic nature and involves the following steps: (1) roasting the raw sulphide under conditions that cause conversion to ZnO and a controlled amount of $ZnSO_4$, (2) leaching and dissolving the ZnO from the calcines using spent electrolyte produced in (4): (3) purification or removal of impurities interfering with the electrodeposition of Zn and contaminating the deposit, (4) electrolysis of the purified solution, whereby it is depleted of some of its Zn with the regeneration of equivalent H_2SO_4 for reuse in the leaching step; (5) melting the cathode Zn and casting the molten metal; and (6) treatment of residues or precipitates which contain substances possessing value. Most of the raw material is obtained from mixed Pb-Zn ores, which are treated by the flotation process for the production of Pb and Zn concentrates. Co is usually removed by "As purification" in which it is precipitated with As and Cu by the addition of Zn dust. Sodium arsenite and $CuSO_4$ are added to the solution, which is heated and then treated with Zn dust: or by the use of Na-β naphtholate Chlorides are removed by adding of Ag_2SO_4. AgCl is then reconverted to sulphate by treatment with Zn dust and heating with H_2SO_4. Rigid control during purification and accurate analysis enable the concentration of impurities in the feed solution to be maintained within very narrow limits. WHB (7b)

Electrolyses in Fused Phosphates. I. Electrolytic Preparation of α- and β-Tungsten. (Elektrolysen in Phosphatschmelze. I. Die elektrolytische gewinnung von α- und β-Wolfram.) HELLMUTH HARTMANN, FRITZ EBERT & OTTO BRETSCHNEIDER. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 198, 1931, No. 1-2, pages 116-140.

Experiments were made in an effort to deposit W electrolytically from fused alkaline phosphate solution. Pure metaphosphate fusions were found unsuitable for the deposition of pure W, but from a mixture of pyrophosphate, metaphosphate and WO_3 with addition of NaCl, pure W was obtained between 650° and 700° C. Similar results were obtained from a solution of WO_3 in pure $Na_4P_2O_7$. Röntgenographic study of W so obtained indicated a new substance in addition to the already known cubic, body-centered crystal W, this new substance being identified structurally as a β-modification of W. β-W crystallizes cubically according to a characteristic type with 8 building bricks; the length of the cubic edge $a = 5.04$ A. U. Complete agreement is obtained between observed and calculated intensity of the individual lattice planes if the 8 W atoms are arranged in the centers of gravity 000, ½ ½ ½, 0 ¼ ½, 0 ¾ ½, ½ 0 ¼, ½ 0 ¾, ¼ ½ 0, ¾ ½ 0. The new form of β-W is confirmed by quantitative chemical analysis and testing weight constancy through thermal treatment in a high vacuum at 900° C. At about 650° C there is a slow irreversible transformation into the α-form. Above the transformation point W separates only in the α-form, below it in the β-form. During electrolysis in the region of the transformation point the β-form is slowly converted into the α-form. Density determinations show that this is dependent upon grain size. Ha (7b)

Electrolysis in Molten Electrolytes. (Schmelzfluss-Elektrolyse.) J. BILLITER. Vol. 3 of Technische Elektrochemie. Second, enlarged and revised edition. Wilhelm Knapp, Halle (Saale), 1932. Paper, 6¼x9 inches, 196 pages. Price 14 RM.

This volume treats of the production by electrolysis from fused salts of the metals of the alkali and alkaline earth groups and of magnesium, aluminum, beryllium, and cerium, etc.

It is indexed. It probably gives a fairly accurate picture of Continental practice, though even there much of the information given is taken from patent literature, while American practice seems to be judged very largely from patent literature. Some of the same illustrations of calcining kilns for alumina and reduction pots for aluminum are shown as are shown in Edwards, Frary and Jeffries "The Aluminum Industry," but we find no reference to that book. Relatively few references to technical literature are given.

The usual topics are dealt with. The volume is a convenient compilation, but most of its contents are available in English in rather more up to date and authoritative form. H. W. Gillett (7b)-B-

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Calorizing, and Its Applications. WALTER SMITH. *Metallurgia*, Vol. 5, Apr. 1932, pages 207-208.

On calorizing, a layer of $FeAl_3$ is formed on the surface. In use at high temperatures Fe diffuses into this layer and the δ solution results. This material likewise protects the underlying Fe or steel from oxidation. Calorized mild steel or cast-Fe articles can be used at temperatures between 600 and 950 °C. For higher temperatures special alloys must be used. Calorizing increases the life of Ni-Cr alloys and Ni-Cr steels used at temperatures above 1000 °C. JLG (8)

Wire Galvanizing Processes. Part V. GEOFFREY K. RYLANDS. *Wire & Wire Products*, Vol. 7, Feb. 1932, pages 49-51, 56-57.

In this concluding installment, the author maintains the equality of the hot-galvanizing process to the electro-galvanizing method and tries to show that even in the latter method impurities in the zinc coating can occur. Ha (8)

Waterproof Iron Coating for Concrete Walls. *Iron and Steel of Canada*, Vol. 15, Feb. 1932, page 17.

An article, accompanied by 1 photograph, in which a method of surfacing the interior walls of buildings by means of a spray gun with Ferrotite, which is a mixture of powdered iron, accelerator, and water, plus a small amount of cement is described. OWE (8)

Evaporation of Platinum in Vacuum From a Tungsten Filament. JOHN STRONG. *Physical Review*, Vol. 39, Mar. 1932, pages 1012-1013.

Pt may be evaporated in vacuum at temperatures below the fusion or evaporation temperatures of W. This makes possible the substitution of the evaporation technique for sputtering. Previous attempts to evaporate Pt were unsuccessful because it was not possible to heat it sufficiently when a small piece was simply laid in a W coiled filament. The evaporation is easily effected when Pt is electro-deposited onto the W filament. The citric acid Pt plating solution used near 100° C. is satisfactory for this electrodeposition. Best evaporation deposits are obtained when the work is shielded from the hot W filament until after the fusion temperature of Pt has been attained. For the conservation of Pt the filament may be inclosed in a box made from W foil. A window in this box allows the evaporation to be restricted as desired. The Pt deposited on the walls of the box may be dissolved in hot aqua regia or if a Cu box is used the Pt may be peeled off in the form of thin foil. Mirrors, interferometer plates, fibers, etc., may be coated with Pt by this technique with less trouble and better results than by sputtering. WAT (8)

The Causes and the Prevention of Explosions in Silvering Glass. JACQUES WOLF. *Glass Industry*, Vol. 13, Jan. 1932, pages 5-6.

The explosions that occur most frequently in mirror silvering, are those caused by the formation of silver amide and fulminating Ag. The measures to be taken, in order to avoid explosions, are as follows. The ammoniacal Ag and alkaline solutions must be prepared separately and diluted. Solutions must never be mixed in a concentrated condition, but only after each has been diluted according to the prescribed proportions of the process. The silvering liquid must be protected against the sunlight and kept in a cool place. The Ag solution must never be prepared more than one or 2 days before use, the alkaline solution may stand longer with safety. Mix the 2 diluted solutions only immediately before using. The alkaline solution must always be poured into the Ag solution, never conversely. For the preparation of the reduction liquid, the acid must always be poured into the Ag solution, never conversely. Silver nitrate must never be poured into the ammonia, the process must be reversed. WAT (8)

Sherardizing. FRED L. WOLF (Ohio Brass Co.). *Metals & Alloys*, Vol. 2, Dec. 1931, pages 341-342.

The author reports briefly on the experience of his company with sherardizing malleable Fe over the period 1911 to 1923 with results that show this method of protection to be inferior to hot dip galvanizing. Difficulties were encountered in maintaining a uniform product from the sherardizing process. WLC (8)

The Cathodic Projection (Sputtering) of Elements and Various Applications. (Sur la Projection Cathodique des Elements et quelques Applications.) F. JOLIOT. *Annales der Physique*, Vol. 15, Apr. 1931, pages 418-436.

The theory of cathodic projection is summarised with references to the various original investigators. Apparatus for cathodic projection are described. In order to obtain oxide free cathodic surfaces of easily oxidized metals, a secondary cathode is first coated with the desired metal by thermal projection in a very high vacuum. Methods of preparing very thin films (up to 50mμ) without support are described, and the use of cellulose acetate as a preliminary support is described in detail. Thick films may be obtained by sputtering on a cellulose acetate base and then electroplating. Several uses of sputtered metal films are described, including the formation of sensitized photographic plates and the construction of a high-sensitivity, low-inertia bolometer. Methods of measuring the thickness of metallic films are discussed and it is pointed out that the use of densities as given in standard tables leads to erroneous results. 18 references. Ha (8)

Steel-Cored Aluminum. EDGAR T. PAINTON. *Electrician*, Vol. 107, Nov. 27, 1931, pages 733-735.

Steel-cored Al is being used extensively in transmission lines throughout the world. Where steel-cored Al has but one layer of Al over the core the galvanized core may be dipped in a bituminous solution before stranding up the cable. The latest important development is the use of sector-shaped Al wires instead of wound wires, resulting in a reduced diameter with the accompanying economy. WHB (8)

Hard Facing in the Steel Industry. W. A. MOORE. *Welding*, Vol. 3, Feb. 1932, pages 88-91.

A good wear-resisting metal should possess the quality of red hardness to a marked degree. The author tells how money can be saved by applying hard-facing materials on parts subjected to excessive abrasive wear. Many applications of hard-facing of steel mill machinery parts are explained and illustrated. TEJ (8)

Molybdenum Contacts for Rapid Regulators. (Molybdänkontakte für Schnellregler.) W. von Berlepsch-Valendas. *Elektrotechnische Zeitschrift,* Vol. 53, Jan. 21, 1932, page 64.

Mo proved to be greatly superior to Ag for rapidly operating contacts of a hammering motion, particularly if one contact is flat and of a larger surface than the other contact which has a concave surface so that the actual contact is annular. Such contact operated over 5,500 hours before regrinding was necessary, against 100 hours of Ag contact. Ha (9)

The Different Bronzes Employed by the Railroad Companies. (Les Différents Bronzes utilisés par les Compagnies de Chemins de Fer.) R. Loiseau. *Cuivre et Laiton,* Vol. 5, Jan. 30, 1932, pages 33-37.

This is a tabulation of the various bearing metals used by the French Railroad Companies; their composition and application are described. See also *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 67. Ha (9)

Alloys of Copper Used in Marine Service. (Les Alliages de Cuivre Utilisés dans la Marine). M. Ballay. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Nov. 1931, pages 560-574.

In this article is brought to light the progress realized on the development of Cu alloys and their uses during the last years, as has been recorded in the metallurgical literature. GTM (9)

Light Metal in the Automobile Fire-Ladder. (Leichtmetall im Automobil-Drehleiterbau.) Castner. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, pages 402-404.

General description and illustrations. Ha (9)

Magnesium and Its Alloys. (Le Magnésium et ses Alliages). R. Cazaud. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Oct. 1931, pages 504-513.

This is an extension of a previous article, "Le Magnesium et Ses Alliages," *Aciers Spéciaux, Métaux et Alliages,* Mar. 1929, pages 83 and 131. The advantages in using Mg alloys in aeronautical construction are well emphasized in this paper. GTM (9)

Points on Making Duralumin Tanks and Riveted Joints. A. Eyles. *Machinery,* Vol. 38, Oct. 1931, page 135.

Duralumin sheets used in fabrication of tanks are generally heat treated to increase tensile strength. They are heated, quenched and aged. Heating may be done in furnace or salt bath. Electricity, gas or oil may be used but coal, coke and charcoal should not be used as they form explosive mixtures. Tanks should be riveted as welded joints often suffer from corrosion. Rivets should be of the same material as that welded. RHP (9)

Casting of Bronzes which have to Withstand Pressure. (Les Moulages de Bronze devant resister a la Pression.) M. Gossieaux. *Cuivre et Laiton,* Vol. 5, Jan. 30, 1932, pages 39-40.

A brief description and discussion of the bearing metals used in the American Navy, and the practice of molding and casting. Ha (9)

Driving Rods of Duralumin for Locomotives. (Lokomotiv-Pleuelstangen aus Duralumin.) *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, page 401.

It is reported that the results of the past 10 months are satisfactory. Ha (9)

Nickel and Its Alloys Used in Decorating. (Le Nickel et ses Alliages dans la Décoration.) By the Committee of Studies of "Centre D'Information du Nickel." *Aciers Spéciaux, Métaux et alliages,* Vol. 6, Aug. 1931, pages 383-403; *Revue du Nickel,* April 1931, page 35.

General remarks on the uses of Ni as a decorating medium. Topics discussed are Ni and Cr plating, use of Cu—Ni alloys, pure Ni, Monel metal, and the uses of 18:8 non-corrosive alloy. GTM(9)

The Longest Fire-Ladder of Light Metal in the World. (Die längste Feuerwehrleiter der Welt aus Leichtmetal.) Castner. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, pages 406-410.

The ascendable height of the ladder is 135 ft., which can be increased to 155 ft. The number of rungs to be climbed is 165. The parts are joined together by riveting. Details of construction and illustrations are given. Ha (9)

Nickel Cast Iron for Pistons and Cylinders. Thomas H. Wickenden (International Nickel Co.). *Machinery,* Vol. 38, Oct. 1931, page 140.

Abstract of a paper before the Society of Automotive Engineers. Paper given in full in the S. A. E. Journal, Vol. 29, Oct. 1931, pages 328-331. See "Nickel Alloys in Automotive Manufacture," *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 67. RHP (9)

Despite Low Tonnage, Nickel Alloys and Plating Processes Gained Momentum in 1931. Robert C. Stanley (International Nickel Co.). *Automotive Industries,* Vol. 66, Feb. 20, 1932, pages 254-255.

Research effort achieved brilliant results which will be employed when business swings back to normal level. Ni plating, Ni alloys, various uses of Ni and Monel metal are described. The "T" Ni welding wire has been found successful in both gas and electric welding. DTR (9)

Progress in the Construction of Tank Cars. (Fortschritte im Tankwagenbau.) H. Staffehl. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, pages 399-401.

A few recent constructions are described, especially tank cars with measuring chambers by which the customer can see for himself that he gets the proper amount of liquid; a great number of claims is said to have been eliminated in this way. The saving in weight of the empty car resulted in a greater carrying capacity. Ha (9)

Building First Long-Span Bridge in Maine. D. B. Steinman & C. H. Gronquist. *Engineering News-Record,* Vol. 108, Mar. 17, 1932, pages 386-389.

The Waldo-Hancock suspension bridge features twisted-wire strand cables, Vierendeel-truss-type towers, and continuous girder approaches. The bridge is fully described and is of the latest of the twisted-wire strand cable structures so far built. CBJ (9)

Aerial Lead-Covered Cable. Paul Suransky (Pacific Gas & Electric Co.). *Electric Light & Power,* Vol. 9, Nov. 1931, pages 21-23.

Pacific Gas and Electric Company has installed 8.2 miles of aerial cable having commercially pure Pb sheaths, 7.5 miles of which have been installed 5 years or more. High strength galvanized guy wire of various sizes was used as the messenger. Metal cable rings, spaced 15-18 ins. apart, were used to suspend the cable from the messenger. Experience with the cable has been unsatisfactory. In a run of 3300 ft., 32 breaks were found in the Pb sheath. These occurred about 1.5-2 ft. from the attachment to the cross-arm, where the rings had become displaced and allowed the cable to sag. The breaks indicated fatigue of the Pb sheath. It is believed, however, that satisfactory performance can be obtained if the cable has 1% Sb in the Pb sheath, and if careful consideration is given to its installation in order to obtain the required sag of the messenger. MS (9)

The Use of Aluminum Alloys in the Construction of Railroad Cars and Street Cars. (Die Verwendung der Aluminium Legierungen im Eisenbahn und Strassenbahnwagenbau.) Felix Thomas. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, pages 386-399.

The paper reviews and compares the present utilization of Al alloys for the construction of railroad cars and street cars, their application in different countries with tables of steel and Al cars, and the materials used. The saving in operating cost is usually considerable, comparative figures from France, England, U. S. A. and Germany are tabulated. Vehicles and details of construction are illustrated. Ha (9)

Construction of Winding and Ventilation Shafts of Steel in Westphalian Coal Mines. (Ausbau von Hauptförder-und Wetterstrecken in Stahl auf westfälischen Steinkoklengruben.) Vollmar. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, Mar. 14, 1931, pages 317-320.

Rigid and elastic constructions of different sections are described and the details of joining the parts and segments illustrated. 14 references. Ha (9)

Iron or Wood Ties? (Eisen- oder Holzschwelle?) Rudolf Vogel. *Stahl und Eisen,* Vol. 52, Feb. 18, 1932, pages 166-169.

Discussion of pros and cons for iron and wood railroad ties. Graph is given showing life of iron ties and pine-wood ties saturated with $ZnCl_2$, $ZnCl_2$ + tar oil, tar oil by Rüping's method. Rüping's method of soaking pine-wood ties in tar oil gives longest life next to iron ties. DTR (9)

Light-Weight in Car Construction. A. H. Woolen. *Railway Age,* Vol. 91, Aug. 1931, pages 283-286.

The Use of Light Metals in the Swiss Postal Administration. (Die Verwendung von Leichtmetallen in der Schweizerischen Postverwaltung.) von Salis. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, pages 365-375.

A number of trucks for transportation of mail, automatic doors, trailers, conveyors, etc., made of Al and light alloys are described and construction details illustrated. Ha (9)

Interurban Railroad Car of Light Metal. (Leichtmetal-Stadtbahnwagen.) G. Wagner. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 3, Dec. 1931, pages 376-385.

The detailed construction of motor-equipped cars and trailers of the German State Railroad is described; the weight of the former is 18 tons, the latter 12.5 tons; a saving against steel cars of 9% and 10% respectively was obtained. Ha (9)

German Steel Frame Constructions and Comparison with Concrete and Reinforced Concrete Structural Work with particular Reference to Hoist Frames. (Der deutsche Stahlfachbau und sein Verhältnis zum Beton- und Eisenbetonbau, insbesonders beim Fördergerüstbau.) L. Schmitz. *Montanistische Rundschau, Stahlbautechnik,* Vol. 23, June 16, 1931, pages 49-54; July 16, 1931, pages 57-59.

The author gives experiences gained on the utilization of steel in structural work on the continent. Attention is focussed on some characteristic hoist frames which are compared with reinforced concrete constructions of the same kind. The writer emphasizes the merits of steel constructions which he claims to be superior. EF (9)

The Use of Non Ferrous Metals by the Steam Railroads. Frances A. Westbrook. *Metal Industry,* N. Y., Vol. 30, Feb. 1932, pages 49-50.

Some of the most important uses of Cu, Zn, Pb, Ni, Al, Sn, and the extent to which they are used are mentioned. PRK (9)

Precautions in Using Stainless Steels, Monel Metal and Chromium Plate for Bearings. George A. Luers. *Machinery,* Vol. 38, Dec. 1931, page 254.

These metals are good for corrosion resistance but sometimes give trouble when used together in sliding or rotating parts. The accompanying table shows what action may be expected.

Two metals in frictional contact	Results
Stainless steel and monel metal	Seizes
Stainless steel and bronze	Fair
Stainless steel and babbitt	Best
Monel metal and stainless steel	Seizes
Monel metal and bronze	Seizes
Monel metal and babbitt	Best
Chromium plate and chromium plate	Seizes
Chromium plate and steel	Seizes
Chromium plate and cadmium plate	Fair for limited use
Chromium plate and bronze	Good
Chromium plate and babbitt	Best

Mechanical Specifications. *Automotive Industries,* Vol. 66, Feb. 27, 1932, pages 304-364.

Specifications for American, British and Continental motor vehicles, tractors, Diesel engines, airplane engines, etc., are given in complete detail. Summary of all specifications valuable to manufacturer, distributor and consumer. DTR (9)

JOINING OF METALS & ALLOYS (11)

Soldering (11b)

How to Obtain Good Results With Silver Solder. F. J. Giroux. *Welding*, Vol. 3, Mar. 1932, pages 161-162.

Silver solders vary in tensile strength from 40,000 to 60,000 lbs./in.^{2}. Their melting points range from 1325° F. to 1600° F. according to the amount of Ag contained, and their electrical conductivity depends upon the Zn content. The author gives information on soldering procedure for various alloys, discussing proper application of heat and the compositions of fluxes used. Borax and boric acid are good fluxes for Ag solder. Discussion of paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in Journal of the American Welding Society, Vol. 10, Sept. 1931, pages 22-26. See *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 71. TEJ (11c)

A. C. Arc Welding. *World Power*, Vol. 27, Feb. 1932, pages 89-90.

A new type of alternating current welder has been developed in which an oscillator is used to stabilize the A. C. arc. The oscillator applies a high-frequency discharge at a comparatively high voltage to the welding terminals in parallel with the welding current. This keeps the path of the arc ionized. By means of the oscillator, as soon as the electrodes are brought within welding distance of the work, the arc starts itself. The welding transformer is constructed so the current can be adjusted in small steps. The oscillator is made up of a voltage transformer, spark gaps, condenser, and air-core choke coil. The A. C. arc has an advantage over the D. C. arc for work on thin materials because its penetration is somewhat less. Greater penetration and speed can be obtained by using a larger electrode and a higher current. In strength the welds made by the A. C. arc compare favorably with D. C. welding. WAT (11c)

Progress in Aluminum Welding. (Fortschritte im Aluminiumschweissen.) *Die Metallbörse*, Vol. 21, June 27, 1931, page 1205.

The present state of hammer and gas welding and electric welding applied to Al is summarized. The following analyses of low alloyed Al suitable for welding are included:

	%	%	%	%	
Cu	1.3	2.25	2.0	2.25	
Ni	1.3	1.3	1.3	1.3	
Mg	0.1	1.6	0.8	1.6	
Fe	1.0	1.4	1.4	1.4	balance: Al
Ti	0.18	0.1	0.1	0.1	
Si	2.2	1.25	0.7	0.5

A Discussion of Piping Design. Herbert P. Smith. *Welding*, Vol. 3, Jan. 1932, pages 43-46; Mar. 1932, pages 179-182.

The text of this article is the author's views and opinion of the paper entitled "Frictional Resistance and Flexibility of Seamless-Tube Fittings Used in Pipe Welding," presented by Sabin Crocker and Arthur McCutchan at the Annual Meeting of the American Society of Mechanical Engineers, at New York, Dec. 1-5, 1930. The author states that pressure drop or frictional loss is not increased by the flow of fluids through short radius pipe bends. Part II. Design methods for welded square type expansion loops and their cost of installation. TEJ (11c)

Present Practice in Rail Bonding. Pliney P. Pipes (Ohio Brass Co.). *Paper presented to the 32nd Annual Convention of the International Acetylene Association*, Chicago, Nov. 1931, 4 pages; *Journal American Welding Society*, Vol. 10, Nov. 1931, pages 44-45.

Rail bonds for carrying propulsion currents on electrified roads and for maintaining tract circuits for control of railway automatic signaling, can be applied quickly and economically with the oxy-acetylene torch and a Cu alloy rod. These bonds have low permanent contact resistance and a shearing strength of about 30,000 lbs./in.^{2} This practice is approved by the American Railway Engineering Association. Ha + TEJ (11c)

Tract Joint Construction Methods. *Transit Journal*, Vol. 76, Mar. 1932, pages 132-134.

Thermit welding is used for repair work under traffic and Butt welding for new construction by the Third Avenue Railway System, New York City. Methods and equipment are discussed. CBJ (11c)

Tests of Welds. *Engineering Experiment Station Bulletin* No. 11, *University of Illinois*, Vol. 28, Nov. 11, 1930, 37 pages.

The paper deals with hand welding of the relatively thin steel plates used in the fabrication of storage tanks for oil and water systems; electric welds and static tests only were investigated. Sixty-six different specimens of weld-rods were used. The V-type seems to be the best for making butt-joints in ½" plates. The weakest rod specimen showed 46,000 lbs./in.^{2}, the average for all was 54,400 lbs. The excess material was machined away so that the sections of body of specimen and of weld was the same; no heat-treatment was applied after the weld. The strengths of the specimens welded by the same workman, but with various rods, were fairly consistent; the lowest average for any one rod being 50,531 lbs./in.^{2}, the highest 60,360 lbs. The strength with uncoated rods was 57,500 lbs./in.^{2} with beads laid longitudinally and 43,300 lbs. transversely. Ha (11c)

Welded Piping Installed in a Private Home. *Welding*, Vol. 3, Feb. 1932, pages 107-108.

Because it is leak proof, such an installation is ideally adapted to a vapor system of heating. The installation included approximately 1,580 linear inches of oxy-acetylene welding. Approximate welding costs are given which include heating, bending, straightening and fabricating. TEJ (11c)

Melting & Refining (12a)

Melting of Aluminum in Crucibles. (Das Schmelzen von Aluminium in Tiegelöfen.) *Die Metallbörse*, Vol. 21, May 16, 1931, pages 915-916.

Discusses the properties of Al which must be borne in mind when selecting crucibles for melting Al and the present state of Al melting technique is considered. EF (12a)

High Frequency Induction Furnace Study—Preparation of Silicon-Aluminum Steels for Generator and Transformer Sheets in High Frequency Induction Furnace. (Zur kenntnis des Hochfrequenz-Induktionsofens V. Ueber die Herstellung von Silizium-Aluminium—Stahlen für Dynamo-und Transformatorenbleche in Hochfrequenz-Induktionsofen.) FRANZ WEVER & GUSTAV HINDRICHS. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung*, Vol. 13, Report No. 194, 1931, pages 273-289.

Includes bibliography of 83 references, 5 tables, 16 diagrams. Exhaustive critical review is given of (1) historical development of various materials used to decrease power losses in this type furnace; (2) effect of heat treatment and grain size on magnetization losses; (3) effect of impurities and alloying elements; (4) summary of all results. It was found with low-alloyed Si steels that remarkable improvement resulted from Al additions. The V_{10} numbers lie below the limiting values for average alloyed sheets, i.e., with a class B steel, containing 0.95% Si, a value of only 1.66 W/kg was attained by addition of 0.99% Al. With high-alloyed transformer steels improvements through Al were in the limits of several hundredths W/kg. Exact influence of Al on power loss number is most apparent with small additions, while an increase of Al above a certain amount practically produces no further improvement. Structure tests of Si-Al steels show plainly that they are subject to same rules as those of Si steels. Best value for power loss number can be obtained only if method of fusion and manufacture are so carried out that an even, uniform, coarse crystalline structure exists in the final product. Al produces lowering of power loss through its deoxidation property of Si steels. Above results obtained on small laboratory scale were all confirmed by means of an 8-ton melt in a basic-lined electric arc furnace. DTR (12a)

Steel Control in America. (Om amerikansk stalkontroll.) TRYGGVE HOLM. *Jernkontorets Annaler*, Vol. 115, Dec. 1931, pages 626-642.

Melting of Scrap Brass in the Reverberatory Furnace. (Das Schmelzen von Altmessing im Flammofen.) E. T. RICHARDS. *Die Giesserei*, Vol. 19, Jan. 8, 1932, pages 5-9.

The different types of furnaces and their fuels, their influence on the oxidation, deoxidation agents, melting and pouring methods are reviewed and discussed. Chips should not be melted in reverberatory furnaces but first briquetted. A table of the heat of combustion of the technical metals for combining with 1 gram-atom oxygen is given. Ha (12a)

Some Effects of Temperature and Iron Oxide in the Manufacture of Basic Open-hearth Steel. W. J. REAGAN (Edgewater Steel Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 469, Feb. 1932, 12 pages.

Gives data obtained from commercial furnaces producing 0.60 to 0.80% C steel. From an extended series of tests it was found that: (1) The amount of FeO in the steel is proportional to that in the slag. (2) The FeO in the metal can be controlled by controlling the melting and working conditions. Fast melting or slow working tend to produce a low FeO content. (3) The % Mn in the steel is inversely proportional to the % FeO in the slag. (4) Rejections increase as the age of the furnace increases, which is due to lower furnace temperatures as the age increases. 2 references. JLG (12a)

The Economy of Using Baled Scrap in Open-Hearth Furnace Operation. J. PANZL & T. DAHMEN. *Rolling Mill Journal*, Vol. 5, Apr. 1931, pages 281-284, 289-290.

An abstract of a translation from *Stahl und Eisen*. (See *Metals & Alloys*, Vol. 2, Sept. 1931, page 182.) The charging time and attendant heat losses in charging with the cheaper grades of scrap iron may be considerably reduced by the installation of scrap baling presses. The author describes the construction, charging, operation, and control and power equipment of a rugged, hydraulically-operated baling press, which produces bales of scrap weighing 1100 lbs. at a capacity of 16,500 lbs./hr. A more powerful press is also described in detail which produces high-density "scrap ingots" weighing 4,400 to 5,500 lbs./bale at a capacity of 17,600 lbs./hr. These ingots are welded internally so completely that they may be forged or rolled directly without being subjected to the melting process. JN (12a)

Mercury Purification. BURROWS MOORE. (Thermal Syndicate Limited) *Industrial Chemist*, Vol. 8, Feb. 1932, pages 63-64.

Hg of high purity was required and absence of the chief metallic impurities usually found, namely, Cu, Pb, Fe and Bi. Distillation in vacuo was found to leave a certain amount of these impurities. A method devised consists of specially constructed apparatus (of fused silica or chemical resistant glass) in three parts, one for washing with reagents, one for drying, and one for filtering respectively. Design of apparatus is given. Washing solutions employed were KOH and HNO_3. Data is given of the metallic impurities present in, crude filtered Hg, product after three distillations in vacuo, and crude filtered Hg after the treatment recommended respectively to illustrate the effectiveness of the latter method. RAW (12a)

Extraction of Antimony in the Copper Refining Process. (Antimonentfernung beim Raffinierprozess von Kupfer.) RAYDT. *Die Metallbörse*, Vol. 21, May 23, 1931, page 966.

The author denies the harmful effect of Sb in Cu up to 0.1%. It is difficult to meet the English specifications of 0.05%. Two attempts to remove Sb according to Kohlmeyer proved to be a failure. First method: Conversion of Sb_2O_3 into Sb_2S_3 by pyrite addition to the melt and volatilization by large steam pressures. Second method: segregation of Sb_2O_3 by cooling down of the melt. The author is nevertheless inclined to believe that a reduction of the Sb content is possible by additions of S. EF (12a)

The Bessemer Process. JAS. CUNNINGHAM. *Metallurgia*, Vol. 5, Feb. 1932, pages 139-141.

Furnace Manipulation Governs Inclusions in Acid Open-Hearth Steel. C. H. HERTY, JR. & J. E. JACOBS (U. S. Bureau of Mines.) *Foundry*, Vol. 59, Nov. 15, 1931, pages 40-42, 44.

Abstract of a paper read before the Western Metal Congress in San Francisco. See "Clean Steels from the Acid Open-Hearth," *Metals & Alloys*, Vol. 2, Oct. 1931, page 224. VSP (12a)

Theory and Practice of the Harris Process. (Theory und Praxis des Harris Verfahrens.) W. JENSEN. *Die Metallbörse*, Vol. 21, Sept. 19, 1931, pages 1737-1738; Sept. 26, 1931, pages 1769-1770; Oct. 3, 1931, pages 1801-1802; Oct. 17, 1931, pages 1856-1857; Oct. 24, 1931, pages 1897-1898.

States 17 chemical reactions underlying the Harris Process, a method of softening Pb by the use of soda salts. The actual consumption of $NaNO_3$ is compared with the amount of salt theoretically determined with reference to 1 kg of As, Sn and Sb respectively. The balance of the paper outlines the commercial accomplishment of the Harris process and shows the successive removal of As, Sn and Sb. The most economical composition of the mixtures employed, mainly consisting of NaOH and NaCl, and the working up of the exhausted salts for the recovery of marketable salts of As, Sb, and Sn is covered. The efficiency and the difficulties encountered in the plant operation are critically discussed. The construction of the Harris apparatus and the capacity of installations according to Harris are given. EF (12a)

Equilibria Between Metals and Slags in the Melt. I. The Equilibrium FeO + Mn ⇄ Fe + MnO at 1550 to 1560° C. (Ueber Gleichgewichte zwischen Metallen und Schlacken im Schmelzflusse. I. Das Gleichgewicht FeO + Mn ⇄ Fe + MnO bei 1550-1560°.) W. KRINGS & H. SCHACKMANN. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 202, Dec. 15, 1931, pages 99-112.

The mass law constant $K = \frac{[Mn]\cdot(FeO)}{[FeO]\cdot(MnO)}$ was determined to 0.0032 ± 0.0005, in percent; the ideal mass-law holds good in this equilibrium. The method of the investigation is described. Ha (12a)

The Influence of Iron Oxide on Sintering and a few Practically Important Properties of Dolomite for Steelworks Use. (Die Einfluss des Eisenoxyds auf Sintering und einige praktisch wichtige Eigenschaften bei Stahlwerks dolomiten.) OTTO KRAUSE & HERMANN GUHR. *Feuerfest*, Vol. 7, May 1931, pages 129-136.

Experiments to determine the influence of Fe oxide on the sintering and on the softening under pressure of dolomitic refractory materials are described, and their causes are discussed on the basis of X-ray investigations. WHB (12a)

Chemical Kinetics of the Open-Hearth Steel Process. ERIC R. JETTE. *Rolling Mill Journal*, Vol. 5, Apr. 1931, page 268.

Abstract of a paper presented at the New York meeting of the American Institute of Mining and Metallurgical Engineers. See *Metals & Alloys*, Vol. 2, May 1931, page 105. JN (12a)

Effect of Manganese in Production of Steel. (Untersuchungen über das Verhalten des Mangans bei der Stahlerzeugung.) FRIEDRICH KÖRBER. (Düsseldorf). *Stahl und Eisen*, Vol. 52, Feb. 11, 1932, pages 133-144.

Includes discussion, 16 diagrams and 13 references. Report 221 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. On basis of laboratory tests equilibrium relations were established between manganese-Fe and slags, consisting of almost all FeO and MnO, in temperature range 1520 to 1950° C. The constants of the Mn-equilibrium between molten metal and slag were calculated by use of simple mass action laws. Values obtained, however, do not fall regularly on a smooth curve, and it was also observed that equilibrium concentrations at experimental temperature are materially altered during the cooling down period. Values for heats of reaction for Mn decompositions, as calculated from curve, agree rather well with those obtained by calorimetric measurement. Oxygen analyses show an almost linear rise of O_2 with temperature. Solubility of MnO in the molten bath becomes almost zero due to solubility of FeO. On the basis of these results, deoxidation-equilibrium diagram of Mn is shown first for liquid deoxidation products. Modifications of this diagram for ideally diluted slags were discussed, as their composition is more or less similar to that of technically pure slags. From a solidification-phase diagram of the system FeO-MnO, and assuming a simple arithmetical increase of the lowering of fusion point of Fe by O_2 and Mn, limits were defined in the concentration planes (Mn)-(O_2) for the separation of liquid and crystalline deoxidation products from metal bath. By means of this complete deoxidation-phase diagram for Mn, for which is also given a diagrammatic sketch of space diagram, the course of separation of slags or deoxidation products for fusion of increasing Mn and O_2 contents were given. The separations which were found by microscopic tests agree absolutely with those of the derived phase diagram. For a series of Thomas fusions, the entire fusion behavior of the metal and slag samples were examined. The changes in content of the foreign substances present in the Fe during smelting operation were discussed. The sharp decrease, of the constants of Mn-equilibrium, is to be regarded as the indication for the sudden change of acid slag characteristics into the basic, which is of particular importance for the metallurgical reactions occurring. Relations between effect of temperature of added ferromanganese and period of time for fusion to take place, and completion of deoxidation, were established. An especially sharp decrease of the total O_2 content was found during solidification of the ingot in mold; these reactions are well illustrated by means of the complete deoxidation-phase diagram. Discussion brings out equilibrium constants for different SiO_2 content of slags. Also effect of calcium metasilicate, calcium orthosilicate, and free lime. DTR (12a)

The Desulphurization of the Steel Bath. (Zur Entschwefelung des Stahlbades.) G. Tammann & H. O. V. Samson-Himmelstjerna. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 202, Dec. 24, 1931, pages 329-336.

A few reactions were investigated which can serve for the desulphurization of the steel bath; the reactions with BaO and soda were stronger than with lime. Pb vapor developing in the steel bath had also a desulphurizing effect. The heats of formation and reaction are tabulated and the times of desulphurization with various chemicals given in diagrams. 17 references. Ha (12a)

Making of Aluminum Alloys Rich in Copper and Nickel. (Herstellung von kupfer- und nickelreichen Aluminiumlegierungen.) Thews. *Die Metallbörse,* Vol. 21, Nov. 23, 1931, page 2059.

Shows how to economically overcome the difficulties due to the high melting point of Ni and Cu and tendency toward segregation. The writer advises pouring both metals together in the liquid state with the observance of some precautions, discussed in the article. EF (12a)

Phosphorus as Deoxidizer for Copper Alloys. (Phosphor als Desoxydationsmittel für Kupferlegierungen.) Thews. *Die Metallbörse,* Vol. 21, Oct. 3, 1931, pages 1802-1803.

The preparation of the P bearing Cu alloys as deoxidizer is anticipated and the handling of "P-bronze" for deoxidizing purposes with special reference to Cu and its alloys is discussed. The effect of P added in excess is considered. EF (12a)

Choice of deoxidizing agents; crucible employed in melting; deoxidizing process; production of pure Ni castings; manufacture of Ni anodes. WHB (12a)

The Metallic Charge in Basic Open-Hearth Operations—Some Factors Affecting Operating Economies. C. D. King. *Yearbook American Iron & Steel Institute,* 1931, pages 387-451.

Includes discussion. The paper is devoted to a treatment of the general principles underlying the conversion of metallic charges into basic open-hearth ingots and covers some important factors influencing operating economies. These include the effect of charges on yields, scrap production, and the possible conversion of some losses into scrap recovery. The influence of types of scrap used and changes in ratios of pig iron and scrap is also discussed and illustrated in tables. Hot metal plants, cold metal plants, and duplex plants are dealt with. The general conclusions are set forth as follows: In any investigation of the effect of the metallic charge in basic open-hearth operations as affecting operating economies, it is necessary to determine to what extent ingot yields can be increased for equal conditions. Assuming that the slag volumes and analyses of slags are as required for the type of steels produced, increased yields can only be accomplished by limiting the pit scrap, steel skull, iron scrap, and iron skull production to a point consistent with the economical operation of the plant concerned. Such an improvement may lead to material savings, the magnitude of which will vary with the efficiency of the practice at the plant in question. Excessive scrap production has a material influence on the final ingot cost and at times may warrant measures which may increase the cost above net metal, but result in a lower cost of net metallic mixture and, therefore, result in reducing the total ingot cost. Further savings are possible at those plants which are in position to convert some part of the losses into scrap credit, namely, the use of open-hearth slag at blast-furnaces and the utilization of checker chamber dust in flue dust sintering operations. The various discussions dealing with changes in proportions of the components of the metallic charge show that within limits the open-hearth furnace is sufficiently flexible to consume varying amounts of pig iron and steel scrap and that under certain conditions these changes may be made advantageously. The success of such changes will depend upon the differentials existing between pig iron and scrap, the effect on production capacity, cost above net metal, and, particularly, on other operating departments. Tables of practical data illustrate the considerations. HA (12a)

Change of Composition of Steel in a Basic Lined Ladle. Melts Made in a Basic Lined Furnace. (Ueber die Aenderung der Zusammensetzung des auf basischem Futter erschmolzenen Stahles in der Giesspfanne.) Peter Bardenheuer & Alfred Ranfft. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 13, Report 195, 1931, pages 291-305.

Extensive number of melts in the basic Siemens-Martin furnace and in the Thomas furnace showed changes in composition of the steel, taking place in the casting ladle during casting period. By skimming the furnace slag from the steel and covering with a neutral protective layer, changes in steel composition were avoided. Reactions of the ladle slag with the ladle lining and the steel are so much more active, the greater the amount and the higher the temperature of slag. Cause for this condition is evidenced by decrease in slag basicity through absorption of SiO_2 and Al_2O_3 by lining. Reduction of oxides in slag with non-Si steel is produced by Mn, and with Si steel, mainly by Si. The higher the Si content, with same conditions, the greater will be residual P as well as reduction of MnO in slag. With large amounts of slag or longer casting period, far greater change in steel composition, particularly enrichment of oxides, may be obtained. The O_2 increase is chiefly due to increase of deoxidation products. In Si steel the O_2 is mainly combined with Si. Discussion of causes of reactions between steel and slag in ladle is excellently brought out. Includes 16 diagrams and 23 tables of data. DTR (12a)

Forging (12d)

Defects in Large Forgings. III, IV. G. A. Smart. *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1038-1041, 1048; Dec. 1931, pages 1107-1110, 1117.

It is of great importance that the forging be worked into shape at a rate such that it is finished with its temperature as near the critical range as possible, so that the proper grain size is obtained. In drawing down an ingot between flat dies, it is important that the die faces be parallel with each other and that the sharp corners on the edges of the dies be removed. If the corners are left sharp, laps or cold shuts will appear on the surface of the forging. To prevent shear cracks in reducing a large round section to a small round section on a pair of flat dies, the stock should be reduced to a square section, the area of which should be approximately that of the round section desired. This is then reduced to an octagon and then to the round section. V dies are also used in reducing to small round sections with good results. Clinks are due to improper cooling of a partially forged ingot. If cooled to below 1000° F., ingot should be properly annealed. Describes proper operation to be followed in the forging of a rotor shaft, a ring and a hollow forging. Part IV. Discusses various processes of heat treating large forgings, such as annealing, normalizing and spheroidizing. MS(12d)

Forging High-Chrome Steels. J. B. Nealey (American Gas Association). *American Machinist,* Vol. 75, Nov. 26, 1931, pages 812-813.

It is very important to preheat in a controlled furnace, separate but adjacent to the forging furnace. Preheating requires at least twice as long as for carbon steels. Preheating temperatures must be kept below the carbon precipitation point for Ni steels and just under the grain growth range for Cr steels. Rapidity of heating in the second furnace is essential. The treatment used in some cases, used as an example of proper treatment of alloys of certain composition is described. RHP (12d)

Forging of Rustless Steel. J. B. Nealey (American Gas Association). *Iron Age,* Vol. 128, Dec. 17, 1931, pages 1544-1547, 1584.

Ordinary steels forge easily at red heats of 1400° F. and up; forging pressures can easily be estimated. When Cr or Cr and Ni are added, in amounts required in stainless alloys, pressures necessary for forging jump 200-300% or more. The addition of greater amounts of S to the 0.12% C-13% Cr steel has done much to advance the use of rustless steel. Favorable machining of KA2 type of steel can be produced only through very accurate heat treatment and close control of forging temperatures. Considerable experimental work on these steels has been done by the General Motors Corp. A definite line of demarcation between preheat and forging heat is controlled by keeping preheat temperature below C precipitation for Ni steels and just under the grain growth range for Cr steels. An analysis of the steel used in making rustless steel golf club heads is given. Welding flanges weighing up to 300-400 lbs. are made of Cr-Ni steels of the 18 and 8 series. VSP (12d)

Shearing & Punching (12e)

A Circular Knife-End Shears for Single Sheets and Packs. (Kreismesser-Saumscheren für Einzel- und Paketbleche.) Louis Frielinghaus. *Stahl und Eisen*, Vol. 52, Jan. 28, 1932, pages 84-86.

Circular shears for single sheets are in common use, and the application of circular knife-end shears for cutting sheet metal and packs of sheets is described. Performance and necessary men given for this type of work. Illustrations of 2 shears in the plant of Schoemann & Co., Düsseldorf are shown, for shearing, No. 1 from 50 to 80, and No. 2, 80 to 100 tons per hr. It is claimed that shears No. 1 do the same work as 3 to 4 ordinary end shears, while shears No. 2 are equivalent to 5 to 6 ordinary shears. Knife renewal after production of 35 to 40 thousand tons of packs. Diagrammatic sketch of circular knife-end shears given. DTR (12e)

Extruding (12f)

The Extrusion Press in the Working of Non-Ferrous Metals. L. G. Mitchell (Brass Co. of Australia Pty. Ltd.) & H. Stewardson (Brass Co. of Australia Pty. Ltd.). *Chemical Engineering & Mining Review*, Vol. 23, Sept. 5, 1931, pages 460-464.

A description of a 1000-ton hydraulically-operated extrusion press manufactured by Davy Bros. at Sheffield. The furnace used for heating the billets is an open-chamber, underfired oil furnace with a hearth sloping from the charging door to the discharging door. The operation is continuous. The billet is extruded from the press and converted into a complete and intricate section. Extrusion has been applied to Sn, Zn, Cu and Al, also certain Cu-Zn, Cu-Al, and light Al alloys. O_2, Sn, As, P, Sb and Bi diminish the extrudability of the brasses, while Fe, Cd, Mg and Si in small quantities are desirable. Defects in extruded rod are classed as: (1) casting, (2) the die, (3) extrusion, and (4) reeling and straightening. Each class is briefly discussed. The flow of metal is down the axis of the billet—toward the center and front. WHB (12f)

Machining (12g)

Use and Abuse of Hacksaw Blades and Band Saws. L. B. Thompson. *Iron Age*, Vol. 128, Nov. 12, 1931, page 1237.

The most common form of abuse is failure to select the proper type of blade for material to be cut. Steel or cast iron require a high tempered saw. The correct tension in adjusting blades in the machine is of importance. To get the full use of the blade, a shim should be placed in the vise. VSP (12g)

Fine-Drilling. (Feinbohren.) *Automobiltechnische Zeitschrift*, Vol. 35, Feb. 10, 1932, pages 74-76.

Methods and machines for obtaining absolutely round, straight and cylindrical holes of smoothest surface are described and some micrographs of surfaces given. Ha (12g)

Tungsten Carbide Tools. *Engineer*, Vol. 152, Dec. 4, 1931, pages 603-604.

Well-illustrated article describing tests made by Alfred Hubert, Ltd., manufacturers of machines for using these tools. Tools used in the tests are built up with a Widia tip fixed in a recess cut in a mild steel shank. For tests on cast Fe speeds up to 200 ft./min. were used, 2 tools being in operation at the same time. With 4 tools in operation, 273.9 $in.^3$ of material was removed per min. Widia tools will stand any amount of compression but rubbing or tension quickly destroys the cutting edge. If these tools are run at too slow a speed wear will be rapid and results unsatisfactory. The machines used must have the necessary power and stability to give an even drive without vibration. LFM (12g)

A Test for the New Carbide Cutting Tools. A. W. Swanson. (Illinois Tool Works.) *Machinery*, Vol. 38, Dec. 1931, pages 265-267.

Suggests a test be made on a lathe using 3/32 in. depth and a feed of 0.020 to 0.030 in. at moderate speed, the lathe to be stopped every two minutes to examine the face of the tool. Whether a roughened surface resembling a crater appears is the test of its value for the particular operation. RHP (12g)

Machinability and Strength Properties of Steel and Cast Steel (Die Zerspanbarkeit und die Festigkeitseigenschaften bei Stahl und Stahlguss). A. Wallichs & H. Dabringhaus. *Maschinenbau*, Vol. 9, Apr. 17, 1930, pages 257-262.

Machineability test data plotted on semi-log paper show that doubling of feed reduces permissible cutting speed twice as much as doubling of chip thickness. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 43. (12g)

Use of Tungsten Carbide and Other Hard Cutting-Tool Materials Gaining. Coleman Seller (William Sellers & Co.) *Iron Age*, Vol. 128, Dec. 17, 1931, pages 1560-1563.

An abstract of a report of the sub-committee on metal cutting materials presented at the annual meeting of the American Society of Mechanical Engineers. The data presented was obtained from a canvass to determine the present status of the use of W and Ta carbides and other new cutting materials. The report stresses the need for scientific data regarding their applications. A number of tables are included. VSP (12g)

Machining of Steel is Conditioned by Quality of Metal. H. H. Bleakney (Department of Mines, Canada). *Iron Age*, Vol. 128, Dec. 24, 1931, pages 1608-1609, 1662.

The difficulty of machining is experienced in direct proportion to the number, size and hardness of the inclusions—other things being equal. Such inclusions as alumina and hard silicates, if present in excessive amounts, dull tools and cause poor performance, while manganese sulphide greatly promotes machineability. The effect of structural condition of steel upon machineability far outweighs the influence of inclusions. The best machineability is encountered when both hardness and ductility of steel are at a minimum. An annealed product, with a uniform lamellar pearlite, means smooth and rapid operations on the machine with excellent tool life. VSP (12g)

Drawing & Stamping (12h)

Effect of Wire Drawing Solution on the Power Required in Drawing of Ingot Steel Wire with Krupp-Widia Dies. (Ueber den Einfluss des Schmiermittels auf den Kraftbedarf beim Ziehen von Flussstahldraht mit Krupp-Widia-Ziehsteinen.) Anton Pomp & Albert Koch. *Mitteilungen Kaiser-Wilhelm Institut für Eisenforschung*, Vol. 13, Report No. 193, 1931, pages 261-271.

Two steel wires of following analysis & properties:

	Diam.	C %	Si %	Mn %	P %	S %	T.S. kg./mm.²
Ingot steel wire	A (5mm)	0.06	trace	0.43	0.029	0.035	36
" " "	B (4mm)	0.53	0.22	0.73	0.016	0.035	1004

were pickled in cold 2% H_2SO_4 for 1 to 2 hrs., rinsed with H_2O, and placed in milk of lime tank for 3 days, then dried in air before being drawn. The 2 wires were each drawn down to 4.0, 3.2, 2.6 and 2.1 mm. wires, average cold roll reduction of 35%, with varying angles of die 6, 9, 12, 15 and 18. Before and after each draw wires were gauged, T.S., power required for drawing, longitudinal stress, efficiency of stress, and appearance of wires were all noted. Powdered dry soap, rubbing oil, drawing oil, soda grease, and lime grease were the different wire drawing solutions or lubricants used. Rate of drawing wires was 1.5 m/s. Efficiency of stress was used as reference standard and is given by $\eta \text{ stress} = \frac{\text{A Theoretical}}{\text{A Total}}$ as developed by Pomp, Siebel, and Houdremont. Powdered soap was found to be a suitable lubricant, giving greatest number of draws, without causing grooves or roughening. Rape seed oil and drawing oil behaved alike, producing a rough wire on the 4th draw with wire A; however they were satisfactory for wire B. Greases or fats were poor lubricants. For wire A the most suitable die angle was 15°; with increasing hardness of material the die angle became smaller for good work. Effect of drawing speed on power required could not be accurately determined, no large differences in amount of power was required for different drawing speeds from 0.6 to 5.0 m/s. DTR (12h)

Graphic Methods for Determining Percentage Reduction of Area of Round Rods. L. W. Luff. *Wire & Wire Products*, Vol. 7, Feb. 1932, pages 44-45.

For the production of various tempers in the production of cold drawn rods and wires, charts are developed from which the required solution in a given case can be taken. Ha (12h)

The Production of Shaped and Fancy Tubes. *Metal Industry*, London, Vol. 39, Dec. 18, 1931, pages 581-582.

The method of manufacture of tubes and sections of thin gage by cold drawing is described. PRK (12h)

Reverse Drawing of Conical Shells. Paul Homer White. *Machinery*, Vol. 38, Nov. 1931, pages 174-175.

Description of a method in which the shell is turned inside out in the final operation which eliminates 2 draws and produces a smooth surface. RHP (12h)

Sliding Scale for Determining the Amount of Mixture and the Weight of Raw Material in Stamped Parts. (Schiebertafel für die Rohmengen- und Rohgewichtsbestimmung von Stanzteilen.) Hans Schmid. *Maschinenbau*, Vol. 10, Aug. 20, 1931, pages 529-531.

A new graphic method for determining the amount and weight of crude material in stamped parts is presented. The results in which all the waste material will be accounted for are obtained by a simple method in which it is only necessary to regulate the finished product. MAB (12h)

Technique of Steel Wire Drawing at High and Very High Resistance. (Technique du Tréfilage des Aciers à Haute et à très Haute Résistance.) G. de Lattre. *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Oct. 1931, pages 487-503; Dec. 1931, pages 623-643.

In this present study the author deals with the technique of wire drawing of steels containing carbon 0.4% to 0.9%. This analytical and critical study covers all the phases concerning wire drawing based on scientific treatment. In a general manner, the author introduces first the (a) preparation of wire, (b) the wire drawing, and (c) the finishing. As this paper is divided into chapters, the first chapter deals with the quality of metal. In the second chapter, the general theory of wire drawing is completely treated. Chap. 3 continues with the heat treatment of steel wire. Pickling is also completely discussed in Chap. 4 and in Chap. 5, the lubricants are considered. $CuSO_4$ and $SnCl_2$ and lead salt solutions are usually considered as successful lubricants by the virtue of chemical interchange between Fe and the metal of the salt, which metal deposits on wire. GTM (12h)

Forming Brake Drums for Lincoln Cars. J. B. Nealey (American Gas Association). *Iron Age*, Vol. 128, Nov. 12, 1931, pages 1228-1229, 1281.

Describes equipment and method used by the Lincoln Motor Car Co. in forming brake drums. Blanks for the drums are formed to final shape in a single operation. Press used weighs 125 tons and will exert a pressure of 1000-1500 tons. Furnace is a gas fired semi-automatic. VSP (12h)

Press Brake Dies and Auxiliary Equipment. F. H. Pfefferle (The Cincinnati Shaper Co.). *Metal Stampings*, Vol. 4, June 1931, pages 517-519.

Describes and illustrates the types of dies used in press brakes for forming deep boxes and discusses the design and operation of press brake accessories; such as spring pads, universal gages, universal and standard filler blocks, the ram clamp, and tongues for holding these dies in place. JN (12h)

Press Brake Forming Dies. Part II. F. H. Pfefferle (Cincinnati Shaper Co.). *Metal Stampings*, Vol. 4, May 1931, pages 423-425.

The author illustrates the types of dies used in press brakes and discusses the various operations involved in forming partially closed and completely closed beads, narrow gage channels, wide shallow channels and square posts in metals up to 14 gauge. The operations required in forming the single lock seam for joining 2 metal sheets and the Pittsburgh slip seam for joining 2 sheets at right angles are described in detail. JN (12h)

Cleaning (12k)

Degreasing Metals by the Vapor Process. E. V. D. WALLACE. *Monthly Review, American Electroplaters Society,* Vol. 18, Dec. 1931 pages 6-15; *Metal Industry,* N. Y., Vol. 30, Feb. 1932, pages 53-55.

Includes discussion. Paper presented at the Rochester Convention, 1931, of the American Electroplaters Society. The "Carrier Vapor Degreasing Process" is described as one for the removal of oil or grease from metal objects by immersing them in the vapor of a chlorinated solvent. Boiling trichlorethylene was kept in a Cu tank without cover, but heated by steam near the bottom and equipped with cooling coil near the top and above the vapor layer. Cold water was used in the coil to condense the vapor and prevent its loss through diffusion into air. Objects may be cleaned in 20 sec. in this vapor; an additional ½ to 2 min. may be required to allow solvent which has been condensed on the object to drip back into the bottom of the tank. Cost of operation with this process was estimated to be lower than all other metal cleaning processes. PRK + LCP (12k)

Degreasing of Metal Parts. (Entfettung von Metallteilen.) HANS HEBBERLING. *Oberflächentechnik,* Vol. 9, Feb. 1932, pages 33-35.

Methods of degreasing are discussed; where boiling is not possible, trichlorethylene has proved to be very effective. A few apparatus are described, tanks, in which the treatment can be carried out without injury to the workman, as inhaling trichlorethylene has an intoxicating and eventually toxic effect. Ha (12k)

New Washing Machine for Metals. *Brass World,* Vol. 28, Mar. 1932, page 60.

The Rex Products & Mfg. Co., Detroit, Mich., has marketed a vertical type machine for washing metal products of many kinds. "Penn-A-Chlor" is a special cleaning agent used in the machine and claimed to be a non-explosive non-inflammable, permanent, and acid-free both as liquid and as vapor. The work is placed on a conveyor and passes downward into the machine between powerful streams of boiling solvent, striking from all directions at a pressure of 35-lbs./in.^{2} Work and conveyor then pass upward, then through a rinse of distilled, hot solvent, and then upward and leaves the machine clean and dry. The process is most suitable for cleaning Zn or Pb coated metals, Al die castings or soft metals affected by ordinary alkali cleaners. WHB (12k)

The Bullard-Dunn Process of Cleaning. F. T. TAYLOR. *Monthly Review, American Electroplaters Society,* Vol. 18, Aug. 1931, pages 17-22.

Includes discussion. Paper before Philadelphia Branch of the American Electroplaters Society. Removal of scale or oxide film from iron and steel is effected by a cathodic treatment at 60-75 amp./ft.^{2}, 150° F. for a few minutes in a solution of H_2SO_4, chlorides and a small amount of Pb. During this treatment, the scale is said to be pushed off by the H generated between the metal body and the scale and, at the same time, a thin, adherent layer of Pb is deposited on the clean metal. This process does not etch the metal and has no danger of over-treatment. Pb anodes are used. See also *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 21. LCP (12k)

Automatic Metal Washing Machine. R. BELL. *Engineering Progress,* Vol. 13, Jan. 1932, pages 17-19.

Metals may be rapidly and economically cleaned with an automatic machine made by Hahn & Kolb, Stuttgart. Material to be cleaned is fed to a belt which travels through sprays of hot alkaline solutions. RHP (12k)

Cleaning Silver by Electricity. R. W. KENNEDY. *Electrical Review,* Vol. 110, Jan. 29, 1932, page 164.

To clean silverware rapidly and effectively at home, a china or enameled bowl is filled with a hot 5% washing-soda solution. The negative lead from a storage-battery is attached to the article to be cleaned, which is then totally immersed in the solution. A lead from the positive terminal is next immersed in the solution within an inch or two of the article under treatment. The Ag becomes brilliantly polished. The article is rinsed in warm H_2O and dried. No loss of Ag takes place by this method. MS (12k)

Polishing & Grinding (12l)

Curved Profiles Require Special Grinding Methods. *Abrasive Industry,* Vol. 13, Feb. 1932, page 20.

For accurate grinding of complex curved or angular surfaces it is necessary either that the wheel or the work be moved in such a path as to generate the required surface, or that the wheel be formed to cut its special shape into the work. The latter is known as form grinding. For form grinding, standard cylindrical or surface grinding machines may be used as contrasted to generating methods which require special machines. Few grinding machines have power enough to drive a formed grinding wheel greater than 10 in. in width. Grinding wheels of greater width are expensive and difficult to handle. The heat generated increases as the width of the cutting surface contact increases. These factors combine to limit the width of the surface cut with one wheel. In the generating method, a simple surface moved in the path required will generate a more complex surface. A straight grinding wheel can be caused to cut a concave or convex surface of revolution simply by swinging the axis of the grinding wheel about a point which is to be the radius of the surface to be cut if the periphery of the wheel is straight and has appreciable width. WAT (12l)

Modern Polishing Methods in Cleaning Ornamental Castings. *Abrasive Industry,* Vol. 13, Feb. 1932, pages 32-33.

Modern ornamental cast metal is superior to that formerly made. Some of the abrasive operations followed in cleaning and finishing Al and Monel metal castings are briefly described and illustrated. WAT (12l)

Correct Cutting Action in Surface Grinding. *Abrasive Industry,* Vol. 13, Jan. 1932, pages 15-16.

Plane surface grinding differs from cylindrical grinding in the positioning of the work and the wheel. The area of contact is greater and the rate of movement of the work in respect to the wheel is different. The work speed of traverse or ordinary surface grinding machines cannot be increased to change the wheel-cutting action. Wheel speed is the only adjusting factor. WAT (12l)

Wheel Speed Governs Production. *Abrasive Industry,* Vol. 13, Feb. 1932, pages 25-26.

The faster a wheel is operating the more cutting points per minute will be presented to the work. Since centrifugal force increases with the square of the velocity, a wheel at a peripheral travel of 6000 ft./min. is subjected to 4 times the strain of one running at a speed of 3000 ft./min. A wheel operated satisfactorily at 6000 ft./min. begins to act soft as it wears away. Correct operating speed on an electrically driven machine is maintained by adjustment of the work rest as the wheel wears. This automatically increases the speed. WAT (12l)

Grinding Magnesium Alloys. W. E. WARNER. *Machinery,* Vol. 38, Nov. 1931, page 170.

Brief discussion. Wheels similar to those used for aluminum may be used at a work speed of 80 ft./min. and a peripheral speed of 1000 ft./min. Silicon carbide wheels give the best results. Should be medium hard and of from 30 to 46 grain. Clogging of the wheel can be prevented by the use of a coolant, either kerosene or a 4% solution of sodium fluoride. Emery must not be used for grinding Mg alloys. RHP (12l)

The Last Achievements of Finishing Technique; Lapping in the Manufacture of Measuring Instruments. (Die letzten Errungenschaften der Fertigungstechnik; der Läppvorgang bei der Herstellung von Messwerkzeugen.) C. BUETTNER. *Werkstattstechnik,* Vol. 25, Mar. 1, 1931, pages 113-116.

The conditions of the lapping process are investigated and the influence which grinding and lubricating agents exert on tool and piece to be lapped explained. Ha (12l)

Notes on Polishing Stainless Steel. W. E. WARNER. *Machinery,* Vol. 38, Nov. 1931, page 181.

Very brief discussion. For polishing, use a fine-count buffing wheel at surface speed of 10,000 to 15,000 ft./min. As an abrasive, use emery powder with tallow or lard oil. For final polishing, use Tripoli powder and finish off with a dry cotton buffing wheel with no abrasive or lubricant. RHP (12l)

How Polishing Abrasives Have Been Improved. HENRY R. POWER (Carborundum Co.). *Machinery,* Vol. 38, Oct. 1931, pages 132-133.

Discussion of manufacture, testing, grading, cohesion and density. The use of aluminum oxide is mentioned. RHP (12l)

The Emery Wheel. F. A. W. LIVERMORE. *Brass World,* Vol. 28, Feb. 1932, page 27.

A high grade of skin glue is most satisfactory to use with the wheel. The glue should not be boiled and is applied with a brush. WHB (12l)

Cylindrical Grinding vs. Accuracy. FRED B. JACOBS. *Abrasive Industry,* Vol. 13, Jan. 1932, pages 12-13.

Accuracy is a relative term inasmuch as no part can be fabricated more accurately than the gages used to test it. To finish parts within close limits, substantial grinding machines must be employed to insure maximum production. WAT (12l)

Complete Descaling before Grinding. FRANK A. DEDRICK (Bullard Co.). *American Machinist,* Vol. 75, Nov. 26, 1931, pages 814-815.

Complete descaling is essential to rapid and accurate grinding. Several tables show the relative time of grinding necessary when the descaling has been done by the scratch brush method and when done by the Bullard-Dunn process. The latter process is more economical. Does not describe either method of descaling. RHP (12l)

Buffing Stainless Steels. L. R. EASTMAN. *Brass World,* Vol. 28, Feb. 1932, pages 33-34.

An attempt is made to cover briefly some fundamental principles, to note the history and outline modern methods of manufacture, classify the raw materials and products in a general way and illustrate basic factors involved in polishing, buffing and finishing of metals. WHB (12l)

Conservation of Grinding Wheels. E. H. FISH. *Abrasive Industry,* Vol. 13, Jan. 1932, page 14.

A grinding wheel may be sharpened by a dresser which loosens the bond so that the dull particles fall off. Abrasive wheel making is described. WAT (12l)

Coloring (12m)

Coloring of Metals. (Coloration des Metaux.) J. MICHEL. 3rd edition, Desforges, Girardot et Cie., France, 1931. Paper, 4¾ x 7¼ inches, 272 pages. Price 25 Fr.

A compilation of rule-of-thumb recipes for producing decorative coatings on metals. Protective coatings are not dealt with. The recipes are empirical and the reader has nothing to tell him whether the recipe is any good or not. Recipes for patinas on steel, copper, bronze, etc. are given. Niello is discussed. The book is apparently intended for the small jeweler. Worthless to the metallurgist. H. W. Gillett (12m) -B-

Sand Blasting (12n)

Cleaning of Castings with Steel Grit on the Rotating Table Blower. (Gussputzen mit Stahlkies am Drehtischgebläse.) H. GOMBART. *Die Giesserei,* Vol. 19, Jan. 8, 1932, pages 3-5.

The results are given of tests made to compare cleaning castings by steel blast instead of sand blast. After 6½ months operation it could be stated that steel grit is very well suited to blast cleaning and that it can be done with the existing apparatus for sand without modification. The surface of the cleaned pieces is smooth and dark gray. The steel blasting process is cleaner and more hygienic than sand blasting. Steel lasts much longer than sand keeping sharper edges much better; it was found that 1 kg. steel grit corresponds to about 30 kg. quartz sand. A comparison of costs gave a saving of 42% in favor of steel blasting, including material and wages, in spite of the considerably higher price of the steel grit (300 Mk. per ton against 15 Mk./ton in Germany.) Ha (12n)

Sandslinging Practice in the Foundry. A. J. S. Shewan & R. Atchison. *Foundry Trade Journal,* Vol. 46, Feb. 18, 1932, pages 111-112.

Paper read before the Lancashire Branch of the Institute of British Foundrymen, and dealing with the operation of a traction type sandslinger in a foundry where the work handled is very general, varying from small, mass-production castings of a few pounds to medium-size castings varying from 500 to 2,000 lbs. OWE (22)

Test Value of Soaking Cupola Charges. W. H. Spencer & M. M. Wolding (American Cast Iron Pipe Co.). *Foundry,* Vol. 59, Nov. 15, 1931, pages 26-27.

Abstract of a paper read at the Chicago meeting of the American Foundrymen's Association. Deals with a series of tests designed to find the effect of varying the soaking time. Results show that no especially beneficial results may be obtained from soaking the charges. It seemed as though more heat was lost through burning the bed during soaking time than was recovered in heating of the charge. Coke burned with natural draft over a long period did not give as much heat to the charge as coke which burned rapidly with the blast on the cupola. A number of tables are included. VSP (22)

The Value of Low Total Carbon Cast Irons. W. West. *Metallurgia.* Vol. 4, Oct. 1931, pages 187-192.

It is pointed out that, as the carbon content of gray iron decreases, the strength increases but the shrinkage also increases. The small shrinkage in high carbon iron is attributed to an expansion resulting from the formation of graphite. Experiments are described in which the effects of Si and C on the shrinkage and strength of iron were studied. The shrinkage was judged by the appearance of an intricate casting. The shrinkage was pronounced in irons containing less than 3.25 percent C. Variations in Si content had little effect on the shrinkage, but increased Si decreased the tensile and transverse strength. JLG (22)

The Electric Furnace in the Steel Foundry. (Le Four Électrique dans la Fonderie d'Acier.) H. Verdinne. *Revue Universelle des Mines,* Vol. 5, Mar. 1, 1931, Series 8, pages 135-138.

A general discussion of the use of the electric furnace in the steel foundry, its advantages with regard to economy and uniformity of product, and its growing use in the Belgian steel plants. Ha (22)

Handling of Graphite Crucibles in Melting Plants. (Behandlung der Graphittiegel im Schmelzbetriebe.) R. Thews. *Die Metallbörse,* Vol. 21, June 27, 1931, pages 1203-1224; July 4, 1931, page 1251.

Experiences gained on the use of graphite crucibles and precautions to prevent premature failure. The exact centering and proper mode of mounting of the crucible, the avoidance of draft, the use of soft-edged tools and the selection of a suitable coke low in S and moisture, the detrimental effect of gas and oil firing are taken up in the first part of the paper. The second part furnishes instructions in regard to proper melting and casting operations while using graphite crucibles mainly stressing the avoidance of sudden changes in temperature on heating and cooling and due to insertion of fresh material. The rough handling with tools is again prohibited. The paper concludes with the utilization of graphite crucibles in tilting furnaces. EF (22)

A Practical Method for Studying the Running Quality of a Metal Cast in Foundry Molds. C. M. Saeger, Jr. & A. I. Krynitsky. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 2, Dec. 1931, pages 513-540.

A test method for determining the "running qualities" of metal was developed. Results indicated that aluminum, brass and cast iron, cast in dry-sand molds ran further than the same metals cast in green-sand molds, and that with an increase in pouring temperature, the length of test specimens increased in a direct proportion. Aluminum is affected by the maximum heating temperature. CHL (22)

Electric Melting—Synthetic Cast Iron. Gilbert S. Schaller. *Western Machinery World,* Vol. 22, Dec. 1931, pages 573-575.

An article dealing with the application of the electric furnace to the modern foundry and the production of cast iron and steel by the acid and basic electric processes. WAT (22)

Cover of an Evaporating Pan made of Silumin. (Herstellung eines Abdampfdeckels aus Silumin.) G. Schüle. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Feb. 7, 1932, pages 64-65.

Description of how the cover (diameter:1500 mm) was molded and cast. GN (22)

Relation Between Shape of Grain and Strength of Sand. H. Ries & H. V. Lee. *Transactions & Bulletin American Foundrymen's Association,* Vol. 3, Feb. 1932, pages 857-860.

Tests on clean sand bonded with ball clay show that mixtures with rounded sand grains have lower permeability and higher compressive strength, in both the green and baked condition, than those with angular grains. CHL (22)

Pipes and Progress. William Phillips. *Foundry Trade Journal,* Vol. 46. Feb. 4, 1932, page 90.

Oil-Sand Practice. B. Gale. *Foundry Trade Journal,* Vol. 46, Feb. 18, 1932, pages 118-120.

Paper read before the Lincolnshire Section of the Institute of British Foundrymen, in which the author discusses a few practical experiments on cores, using different grades of sand, which are referred to as fine, medium and coarse, and different kinds of binders. The article is accompanied by 4 tables. OWE (22)

Some Practical Notes on Oil-Sand Practice. H. W. Keeble. *Foundry Trade Journal,* Vol. 46, Feb. 25, 1932, pages 130-133.

Paper presented before the London Junior Section of the Institute of British Foundrymen, in which the author discusses the advantages to be gained by the use of oil-sand cores, raw materials employed in their production and examples of oil-sand core practice. The article is accompanied by 1 table and 4 photographs. OWE (22)

Electrolytic Process for Making Metal Patterns. Charles O. Herb. *Machinery,* Vol. 38, Dec. 1931, pages 241-243.

The Electro-Chemical Pattern & Mfg. Co., Detroit, Mich., produces metal patterns by depositing Cu electrolytically in plaster molds until a shell of substantial thickness has been obtained. These shells are used for molding surfaces of patterns and cores. Cu shells range from 1/32" to 1/4" in thickness and are backed by white metal. Allowance is made for a single shrink. RHP (22)

Foundry Sand Control. A. A. Grubb. *Transactions & Bulletin American Foundrymen's Association,* Vol. 2, Nov. 1931, pages 8-17; *Metal Industry,* New York, Vol. 30, Feb. 1932, pages 62-63; Mar. 1932, pages 100-101.

An exchange paper to the Dutch Foundry Association. The steps in the introduction and maintenance of sand control in a foundry are clearly described. The advantages arising from same are of extreme importance. PRK+CHL (22)

Electric Process Iron for Cylinder and Cylinder-head Castings. H. E. Bromer. *Transactions & Bulletin American Foundrymen's Association,* Vol. 2, Dec. 1931, pages 585-608.

When demands are heavy a duplex process of melting is used, melting in the cupola and refining and increasing the temperatures in the electric furnace. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. CHL (22)

An Efficient Molding Plant for Cast-Iron Ingot Molds for Steel Ingots. Robert Jones. *Foundry Trade Journal,* Vol. 46, Feb. 11, 1932, pages 105-106.

An article illustrating in detail the methods employed in the molding of cast-iron ingot molds having the big end up. The article is accompanied by 8 figures embodying details of the method of production. OWE (22)

Prevent Losses with Proper Gates and Risers. Pat Dwyer. *Foundry,* Vol. 59, Nov. 1, 1931, pages 47-49; Nov. 15, 1931, pages 37-39; Dec. 1, 1931, pages 47-49; Dec. 15, 1931, pages 26-28.

XX. Top gate has been blamed for conditions due either to sand in the mold or the manner of manipulating the sand. Coarse grade sand properly dried will resist cutting action of metal poured through the top of the mold. Cast iron pipes, constituting about 13% of all gray iron poured into castings in the United States are made by the use of top. Hydrants and other special pipe shapes are molded and cast horizontally and are gated according to a number of methods. A single sprue and a bull ladle suspended from a monorail take the place of multiple sprues. XXI. Incidents are quoted to show how vent passages correctly arranged cured a defect of long standing. The necessity of providing free egress for gas and steam from sand, especially sand surrounded by metal filling the mold is emphasized. Close examination of the defect and knowledge of the factors involved in the production of the casting are required to determine whether the defect is a blow hole, shrink hole or a combination of both. Risers should be kept open until solidification of the casting takes place. XXII. Large sink head, feeder or riser opening is placed on top of the mold to provide a place for reception of dirt coming up on top of iron as it rises in the mold. In many instances, a riser is of no benefit. The use of the reservoir type of head presents many desirable features, including thorough mixing of metal, opportunity for dross and occluded gases to escape instead of entering the sprue, and increasing the pressure exerted on the metal in the mold. Reversal of pattern in the mold will, in some instances, banish shrinkage defect. XXIII. In the manufacture of pulleys, trouble may be encountered in the cracking of spokes and rims, warped and distorted castings. These troubles may be caused by faulty design, faulty molding practice or faulty metal, and often by a combination of two or more of these. Unequal cooling speed is the direct cause of practically all pulley troubles in the foundry. The views of H. N. Tuttle, who covered the subject very thoroughly in the Sept. 1927 issue of Foundry, are included. VSP (22)

Sand Condition is Important in the Steel Foundry. John Howe. *Foundry,* Vol. 59, Sept. 1, 1931, pages 61-62.

Discussion of the amount of old sand that may be used on castings of a given weight and the causes and remedies for scabs on steel castings. Other topics taken up are the use of the proper facing and mixtures for making hard and soft cores. VSP (22)

Principles of Rational Gas Use in Steel Plants. I. E. Agte. *Domez* (Achievements of Metallurgy in U.S.S.R. and Abroad), No. 9, 1931, pages 76-88. (In Russian.)
The mechanism of the combustion of the different gases available in steel plants is described. Except for melting furnaces a gas should be selected to fit the required temperature conditions in preference to the use of recuperators. High pressure burners offer many advantages. (23)

Continuous Heating Furnace and Troubles with its Starting. B. E. Bielsky. *Domez* (Achievements of Metallurgy in U.S.S.R. and Abroad), No. 10, 1931, pages 61-77. (In Russian).
A description of billet-heating furnaces, the troubles encountered in their starting and operation and some of the remedies applied. (23)

Classification of Open Hearth Furnaces and Their Tonnage. L. M. Fortunato. *Domez* (Achievements of Metallurgy in U.S.S.R. and Abroad), No. 10, 1931, pages 1-23. (In Russian).
Better conception of the performance of an open-hearth furnace can be obtained when one considers its metallic yield per unit of bottom area. (23)

Electric Furnaces. *Metallurgist,* Sept. 1931, pages 130-131.
The first cost and the cost of operation of electric furnaces is still the first consideration in their use in spite of the superior quality of their product. VVK (23)

One-Ton High Frequency Induction Furnace. *Metal Industry,* London, Vol. 40, Jan. 1, 1932, page 14.
A general description is given of a 1 ton Metrovick (Metropolitan-Vickers Co.) furnace to be installed in the works of Messrs. Thos. Firth and John Brown Ltd. PRK (23)

Rotating Furnaces for Powdered Coal. (Les Fours Rotatifs au Charbon pulvérisé.) L. J. Gouttier. *Revue de Fonderie Moderne,* Vol. 26, Jan. 10, 1932, pages 1-8.
A detailed description is given of a rotating furnace for melting high-grade cast-Fe and malleable Fe. The furnace makes oscillations of about 45° permitting a very rapid and uniform heating of the charge; during the first period of heating a flow of high grade coal dust is used, later replaced by low grade coal. Operating results are given; about 7.5 kwhrs. were required per ton of material. Ha (23)

The Cleaning of Blast Furnace Gas. Guy Barrett. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 129-139.
A résumé of the knowledge of the wet washing, the electrostatic deposition, and the filtering methods for the cleaning of blast furnace gases is given. CHL (23)

A Comparison of the Use of Various Fuels in Copper-refining Furnaces. E. S. Bardwell (Anaconda Copper Mining Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 457, Feb. 1932, 18 pages.
The Cu-refining furnaces at Great Falls and the successful methods of using lump coal, pulverized coal, oil and natural gas as fuel are described in detail. The lump coal was the least efficient. Powdered coal increased the amount of slag, and the ash dropping on the bath tended to prevent a high rate of heat transfer between flame and bath. The B.t.u./lb. of Cu used with the various fuels were 1627, 1441, and 1670 for pulverized coal, oil and gas, respectively. Natural gas was the ideal fuel from the operating point of view. 2 references. JLG (23)

Hessenbruch. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, No. 13, Report 183, 1931, pages 169-181.
Studies on a high-frequency induction furnace of 300 kg. capacity, fed by a 100 kw. high-frequency generator of 500 periods are described, including the energy consumption and its distribution, the lining of the furnace, the metallurgical reactions, etc. The possibility of reactions between slag and metal are shown to compare favorably with those of an electric-arc furnace. The quality of steel produced in induction furnaces equals that of electric steel. GN (23)

The Fundamentals of Brass Foundry Practice. Part 28. R. R. Clarke. *Metal Industry,* N. Y., Vol. 30, Feb. 1932, pages 62-63.
A description is given of types of furnaces used for melting and alloying metals. PRK (23)

Pulverized Fuel for the Small Unit-Shell Type Boiler, Metallurgical and Chemical Processes. H. W. Hollands & E. C. Lowndes. *Transactions Tokyo Sectional Meeting, World Power Conference,* 1929, Vol. 3, 1931, pages 771-785.
The design of a combustion chamber to convert pulverized coal into producer gas is briefly described. It is small, temperatures are low (result—low upkeep), and ash is not carried into the tubes. Combustion of the producer gas is effected in the boiler tubes or on the working hearth (metallurgical furnaces), giving the highest temperature at point of use. Advantages of pulverized coal in puddling furnaces, steel ingot heating furnaces, forge furnaces, etc., are described. AHE (23)

Combination Burning of Blast Furnace Gas and Pulverized Fuel. Otto de Lorenzi (Combustion Engr. Corp.) *Combustion,* Vol. 3, Mar. 1932, pages 36-40.
Test data on a steam generating unit fired by blast furnace gas and pulverized coal in combination are given. Calculations are described for obtaining coal-gas weight ratios. Control systems and recent developments in furnace design and methods of firing are given for plants using these 2 fuels in combination. DTR (23)

Combination Forge Furnace and Steam Boiler Saves 22 Per Cent. of Forge Shop Fuel. J. B. Nealey. *Gas World,* Vol. 95, Dec. 19, 1931, *Industrial Gas Supplement,* pages 13-15.
The use of waste heat from the forge furnace in the steam boiler which supplies power to the hammer, is described. The way to obtain the closest heat balance possible between the furnace and the boiler and at the same time utilize all the waste heat from the furnace is shown together with the results of a 2 days test run, including the efficiency of the forge in heating steel, the percentage of total heat supplied utilized in heating steel, the overall efficiency, the average horse power developed by the boiler, and the cost of heating steel to forging temperature. Nitriding Furnace and Equipment. W. J. Merten. *Fuels & Furnaces,* Vol. 9, Aug. 1931, pages 895-900; Sept. 1931, pages 1031-1034.
The Bell type of nitriding furnace, its equipment, the process, the design of nitriding containers, the container material and the ammonia tanks are described. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 189. Ha (23)

Combustion Equipment Revamping in Modern Production Plant Proves Profitable. Frank S. O'Neill (Link Belt Co.). *Combustion,* Vol. 3, Mar. 1932, pages 23-25.
Modern foundry practice at the Link Belt Co. plant, Indianapolis, Ind., where pulverized fuel is used for firing, melting furnaces, annealing ovens and steam boilers is described. The installation has effected considerable savings and has greatly improved operating results. Details of automatic control system are described. DTR (23)

Calculation of Wall Losses of Industrial Furnaces. (Die Berechnung der Wandverluste industrieller Öfen.) E. Maase. *Feuerfest-Ofenbau,* Vol. 7, July 1931, pages 97-102; Oct. 1931, page 147.
Diagrams are presented from which the losses due to thermal conductivity and gas permeability as well as the outside wall temperature can be taken directly. A graphical method of evaluating the temperature gradient of a wall consisting of 2 different materials is shown. The viewpoints essential for the calculation of the thermal conductivity of refractories are discussed. A table gives data on the thermal conductivity of various materials employed in furnace construction. EF (23)

The High-Frequency Furnace and its Use for the Manufacture of Steel Castings. T. R. Middleton. *Foundry Trade Journal,* Vol. 46, Jan. 28, 1932, pages 73-75.
The development of the high-frequency furnace, the progress which has been made during the last 4 years in the manufacture of larger furnaces, refractory materials suitable for lining such furnaces, the difficulties met in refining steel in these furnaces and the melting costs involved in this work are briefly discussed. OWE (23)

A Tilting Metal Melting Furnace Fired with Powdered Coal. (Tiegelloser kippbarer Metallschmelzofen mit Kohlenstaubfeuerung.) O. Beckmann. *Metallwirtschaft,* Vol. 11, Mar. 11, 1932, pages 154-155.
The powdered coal is carried by 25% of the air supply of a blower to the burner. The main part of the air is preheated to 250° to 300° C. and enters the burner at right angles to the stream of coal which enters vertically. This results in a long flame which follows a spiral path, with complete combustion of the coal and a higher flame temperature than can be obtained with oil. Combustion takes place in the melting chamber. A typical example is given showing the comparative amounts and cost of oil and powdered coal required to melt a charge. A saving of 55% is obtained by using powdered coal. CEM (23)

Industrial Furnaces for Gas. XII Accessory Equipment. L. E. Biemiller. *American Gas Journal,* Vol. 136, Jan. 1932, pages 32-34.
The principles and applications of temperature measurement and control are outlined. Pressure conditions in gas-fired furnaces are studied. The venting of furnaces in special cases is advocated. CBJ (23)

Electric Heat for the Metal Industries. J. C. Woodson. *Electrical World,* Vol. 98, Dec. 5, 1931, pages 1004-1007.
The present tendencies are: (1) for a rather rapid and extensive expansion of electric annealing (bright and semi-bright) to the wire, strip and sheet mills; (2) the use of artificial furnace atmospheres to secure special and better results; (3) a development of more of the large continuous electric furnaces for sheet annealing and normalizing and with artificial atmospheres; (4) a rather extensive development and application of the principle of inductive heating to numerous heat-treating processes now considered unsuitable. Several installations in various industries are illustrated. WHB (23)

The Design and Operation of Open-Hearth Furnaces. Part IV. C. W. Veach (The Bettendorf Co.). *Rolling Mill Journal,* Vol. 5, Apr. 1931, pages 255-258.
Maintenance costs in open-hearth operation may be reduced materially (1) by the installation of mechanical control equipment to insure complete combustion of fuel gases and maximum transfer of heat from the flame to the charge and (2) by changes in furnace design so that the lasting qualities of all vital parts may be more closely coördinated. Present day tendencies in the control of furnace gases, such as the use of flue dampers in place of reversing valves, the mechanical introduction of air to the checkers, the installation of coils for preheating the air used in atomizing fuel oils, and the wider use of recording instruments and control equipment in furnace operation have reduced the average fuel consumption per ton of steel from between 6 and 8 million B.t.u. to about 4½ million B.t.u. JN(23)

Some Metallurgical Characteristics of Induction Furnaces as Determined by the Absorption of Oxygen by Molten Nickel. F. R. Hensel & J. A. Scott (Westinghouse Research Labs. and Driver-Harris Co.). *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 15 pages.

A rapid method for determining O in molten Ni was developed. It is a modification of the one developed by Herty for the determination of O in molten steel in which Al is added to the metal and the Al_2O_3 determined. Melts were made in a small induction furnace with NiO on top of the charge. The solubility of O in Ni increased with the temperature. The probable Ni-O diagram is given. Comparative tests on the rate of O absorption as affected by turbulence were made in a 60-cycle and a 5,000-cycle furnace (without the NiO cover). The O content increased with the turbulence, for the rate of absorption in the 60-cycle furnace was 3 times as great as in the 5000-cycle furnace. In the 60-cycle furnace O absorption was near saturation. Oxidation could be prevented by melting under an O-free atmosphere by methods described. 5 references. JLG (25)

The Solubility of Gases in Metals. V. H. Gottschalk & R. S. Dean. (U. S. Bureau of Mines). *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 16 pages.

From theoretical considerations and from a survey of published work it is concluded that the simple solubility of gases in metals is extremely small, or for practical purposes negligible. Attention is called to the variable values of solubility obtained by various investigators using methods of great precision. It is suggested that the absorption of gases in metals may be explained by electronic phenomena. Before applying mass-law analyses to metal-gas systems it is necessary to know that the assumptions necessary for their application are justified. In applying these analyses to FeO-C equilibria in steel making processes it is usually assumed that the CO concentration is constant, which is by no means justifiable. 63 references. JLG(25)

Studying the Gases of Simple Steels. Henry D. Hibbard. *Iron Age*, Vol. 219, Feb. 25, 1932, pages 493-494.

Deals chiefly with steels made by the open-hearth process, and is limited to consideration of gases originating in or accompanying the making of steel. The story of the gases of a simple steel demands full knowledge, including source, composition quantity, means for control and effect of the following: (1) those in charge materials; (2) those evolved from metal in furnace during successive stages from melting to tapping; (3) those evolved from molten metal in the mold; (4) those in pipe cavity and in each kind of gas hole in ingot; (5) those retained in solidified steel; (6) those evolved from solid steel when heated to degrees between room temperature and fusion; (7) those evolved from steel when again melted; and (8) those liberated when metal is dissolved by various solvents. Steel scrap is not likely to contain gases of compositions and in quantities which affect the processes of manufacture and properties of the product. VSP (25)

Determination of Oxygen, Nitrogen and Hydrogen in Steel. J. G. Thompson (U. S. Bureau of Standards). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 466, Feb. 1932, 22 pages.

Bibliography of 64 references. A review of the various methods that have been used in determining O, N and H in steel. The interpretation of the results of the various methods are also discussed. It is pointed out that the question of particle size must be considered in relationship to the applicability of the various methods. H is rarely encountered in ferrous materials in excess of about 0.001%. N can be determined by the solution-distillation method or by vacuum fusion. No one method yields complete information with respect to the O in steel. JLG (25)

Hydrogen Absorption of Some Metals at Various Temperatures. (Die Wasserstoffaufnahme einiger Metalle bei verschiedenen Temperaturen.) Thews. *Die Metallbörse*, Vol. 21, Apr. 25, 1931, page 774.

Discusses and tabulates the H_2 absorption of Al, Cu, Co, Ni, Pt, Ag, Sn at elevated temperatures. EF (25)

Critical Studies of a Modified Ledebur Method for Determination of Oxygen in Steel. B. M. Larson & T. E. Brower (United States Steel Corp.). *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 28 pages.

The H-reduction method for the determination of O in steel determines the "diffusible O," which portion is probably effective in modifying the properties of the steel. An improved apparatus by which the amount of diffusible O to within 5 or 10% can be determined is described. The water formed is collected in a weighing tube. The CO and CO_2 formed are made to react with H to form CH_4 by a Ni-Th catalyst. This catalyst, when properly handled, is not poisoned and does not give a large blank. Thin millings are used, and the surface O is removed by a preliminary heating in H at 500-550° C. The sample is heated to 1100-1300° C. in the H. Boats made of pure MgO or ZrO_2 give a rather large blank. Samples can be wrapped in steel foil and suspended in the furnace. The fraction of O evolved as CO or CO_2 varies from 15-25% in ingot iron to almost 100% in high-C steel. Comparative O contents as determined by the apparatus described and by the vacuum fusion method at the Bureau of Standards are given. In some of the low-O steels the O determined by the modified Ledebur method is much greater than the "total O" determined by vacuum fusion. A tool steel analyzed 0.018% O by the former method and 0.004% by the latter. When more O was present (0.025%) however, good checks were obtained. Comparative results on N determined on the same steels by the ordinary solution-distillation method and by vacuum fusion at the Bureau of Standards are also given: the agreement is satisfactory. 17 references. JLG (25)

Influence of Small Amounts of Impurities on Properties of Refined Zinc. O. Bauer. *Metal Industry*, London, Vol. 39, Dec. 25, 1931, page 613.

From paper read before Deutsche Gesellschaft für Metallkunde, Berlin. The shrinkage of Zn is lowered by Cd, Sn, and Mg, whereas Cu, Fe, and Pb have no appreciable effect; Sb is intermediate between these two groups in its effect. The impact value is improved by large percentages of Sn, is little affected by Cd and Pb, and is unfavorably affected by Fe, Mg, and Sb. The Brinell hardness is rapidly raised by Mg, but by Cu and Fe to a lesser degree; it is similarly affected by small additions only of Sb and Cd, whereas Pb and Sn have no effect. PRK (27)

The Effect of Sulphur on the Molten Equilibrium $Fe + NiSiO_3 \rightleftarrows Ni + FeSiO_3$. (Die Wirkung von Schwefel auf das schmelzflüssige Gleichgewicht $Fe + NiSiO_3 \rightleftarrows Ni + FeSiO_3$.) H. zur Strassen. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 200, Aug. 28, 1931, pages 46-56.

The reaction of this composition shows that in the presence of sulphur the equilibrium is changed a little in so far as the distance in the potential series between Fe and Ni becomes smaller and that the reaction follows the ideal mass law. Ha (27)

Scrap. *Metallurgist*, Dec. 1931, pages 179-180.

The question whether scrap shall or shall not be used in the production of non-ferrous metals emphasizes once more the inadequacy of present testing methods and the monumental lack of knowledge we possess of the effect of impurities or of other elements. VVK (27)

Action of Oxides on Pt at High Temperatures. (Über die Einwirkung von Oxyden auf Platin bei hohen Temperaturen). E. J. Kohlmeyer & I. Westermann. *Siebert Festschrift*, 1931, pages 193-214.

The effects of Bi_2O_3, PbO, MgO, Al_2O_3, as well as of silicates, like Marquardt mass, on Pt at various temperatures and of MgO on Rh are described and photographs and micrographs shown. Attack appears to begin when the dissociation pressure of PbO or Bi_2O_3 reaches 3×10^{-2} mm. Hg. Even with the refractory oxides, attack of Pt appears to coincide with an appreciable decomposition pressure of the oxide. It is not clear whether actual reduction of the oxide by Pt is involved. HWG (27)

Micro-Structure and Tendency Towards Brittleness of Lead. (Kristallgefüge und Disglomeration des Bleies.) O. Haehnel (Reichspostzentralamt). *Elektrische Nachrichten Technik*, Vol. 8, Feb. 1931, pages 77-88.

Pb cable sheaths which failed in service precipitated the present investigation on 11 different analyses of Pb to throw light upon the effect of additions of Sn, Sb, Bi, Cu, Zn on the grain size of Pb after solidification. The following observations were made: the largest crystals were noticed in the purest kind of Pb employed (99.997% Pb). However Pb containing 1-3% Sn did not exhibit a substantially smaller grain size after solidifying under analogous testing conditions. The grain size of "pure" Pb was reduced by the different metals studied as follows: 1% Bi = 2/3 reduction, 1% Sb = ¾, 1% Zn = ⅞ and 0.1% Cu = ⅞. Every kind of Pb extruded from a cable press showed a smaller grain size than solidified Pb. However, the purest brand of Pb again exhibited the largest grain. The effect of the additions was approximately the same as in the solidification tests except in case of Sb which caused a more pronounced reduction in grain size after extruding. The grain size of Pb extruded in a cable press depends on undeterminable friction phenomena in the die, on the manner and speed of cooling down after extrusion and on the working temperature and pressure applied. Grain growth of extruded or cold worked Pb is extremely slow at ordinary temperatures. A distinct acceleration of recrystallization takes place at only 40° C. Shocks, for instance vibrations of traffic, result in recrystallization at room temperatures, the rate of grain growth increasing for 5-7 times after 20 years at 18° C. Exposure to the sun rays increased the size of the crystals 10-12 times after 1-1½ years elapsed. Sn (1.3%) and Sb (1%) strongly counteract the formation of coarse grain of extruded Pb cables and 0.1% Cu also reduce the tendency towards recrystallization. The tendency to become brittle, designated as "disglomeration" by the investigator, is not a direct cause of large grain size. This phenomenon is mainly due to vibrations although being more pronounced in coarse grained Pb than in finely crystalline one. The embrittlement is accelerated by rising temperatures. Cracking due to vibrations takes place in Pb with 3% Sn although the grain size corresponds to that of freshly extruded Pb cable sheets. 19 micro-photographs. EF (27)

The Influence of Small Quantities of Aluminum on the Structure of Antifriction Alloys of Sn, Pb, Cu, Sb Rich in Tin. (Influence de petites quantités d'aluminium sur la structure des alliages antifrictions Sn, Pb, Cu, Sb riches en étain). M. Fournier. *Revue de Métallurgie*, Vol. 29, Feb. 1932, pages 108-111.

Micrographic study of 3 alloys with 3% of Cu and Pb containing 5.6 and 8.6% Sb shows that in Sn base antifriction alloys the addition of small quantities of Al (around 1%) produces a pronounced liquation, eliminates cubical crystals of the solid solution and causes a fine globular structure on rapid cooling. JDG (27)

A Study on the Influence of Nickel on the Properties of Lead Bronzes. (Contribution à l'Etude de l'Influence du Nickel sur les Propriété des Bronzes au Plomb.) J. Dessent. *Revue Universelle des Mines, de la Métallurgie*, Series 8, Vol. 7, Feb. 1, 1932, pages 99-102.

The ternary system Pb-Cu-Sn is investigated. Due to its difficult miscibility it often does not give satisfactory castings. A thermal treatment at 700° C. is proposed which gives Cu-Sn surrounded by a pseudo-eutectic Pb-Cu. The addition of 1 to 2.5% Ni adduced considerable improvements in grain and uniformity of structure. Numerous micrographs illustrate the difference due to the addition of nickel in various bronzes. A table of physical data is added. Ha (27)

INSTRUMENTS & CONTROLLERS (28)

An Improved Comparison Source for Measuring Furnace Temperatures. E. M. WATSON & W. P. ZABEL. *General Electric Review*, Vol. 35, Feb. 1932, pages 120-121.

A small pyrometer lamp has been devised that differs from an optical pyrometer in that the objective lens and the telescope are not used. The optical system for the pyrometer lamp and the optical pyrometer are charted for comparison. The operation of the lamp is briefly outlined. WHB (28)

Design Features of Potentiometers. I. MELVILLE STEIN. *Engineering & Mining Journal*, Vol. 132, Apr. 1932, pages 254-256.

Low-resistance potentiometers are shown to have the following advantages over high-resistance types: (1) inherently a low-resistance potentiometer makes possible a higher sensitivity, (2) errors due to current leakage between the potentiometer parts are smaller, (3) low-resistance coils are more stable, (4) power galvanometer damp'ng is easier to obtain, (5) at least 1/10 of the range can be covered with a slide wire resulting in simple and inexpensive construction, and (6) for the same sensitivity, and a low-resistance potentiometer permits using a higher resistance in the volt-box. A Continuous Gas Indicator. *Industrial Chemist*, Vol. 8, Feb. 1932, pages 57-58.

A new design of instrument (B.P. 330799) developed by the Admiralty Research Laboratories. Its action depends upon the comparison of the viscosity-density properties of the gas under test against air in a specially constructed bridge. Diagrammatic layout is shown. RAW (28)

A New Spectral Line Photometer for the Visible Field for the Rapid Analysis of Alloys. (Über ein neues Spektrallinienphotometer für das sichtbare Gebiet zur Schnellanalyse von Legierungen.) G. SCHEIBE & G. LIMMER. *Metallwirtschaft*, Vol. 11, Feb. 19, 1932, pages 107-110.

Contains 6 references. A new apparatus made by R. Fuess in Berlin-Steglitz, which is a combination spectroscope and spectrophotometer. From an ordinary rigid spectroscope with adjustable slit diaphragm the light rays pass through a Wollaston plate, which divides them into 2 beams polarized vertically to one another. The 2 spectra can be observed through a Nikols prism and by turning the prism the intensity of the spectra can be compared. To determine alloy additions or impurities in steel the sample is used either as electrodes for sparks or as the positive electrode for an arc, carbon being used as the negative electrode. By turning the Wollaston plate, which also turns the Nikols prism, and by adjusting the spectroscope slit, a line corresponding to the element to be determined can be moved exactly above an Fe line and their intensity compared. The instrument must first be calibrated, using chemically analyzed samples and choosing suitable lines for each element. The accuracy for quantitative analysis is not as great as in chemical methods, except when very small percentages are determined. The main advantage is the speed of determination, about ½ hour for a complete quantitative analysis of all elements and only a few minutes for qualitative tests. CEM (28)

Thermo Elements (including Rhenium alloys) and the Reproducibility of Their Data. Criteria for Their Utility for Temperature Measurements. (Über Thermoelemente und die Reproduzierbarkeit ihrer Daten -Kriterien für ihre Brauchbarkeit zur Temperaturmessung). W. GOEDECKE. *Siebert Festschrift*, 1931, pages 72-99.

The thermal e.m.f. of alloys of Pt with Ru, Fe, Ta, Os, Re, W, Mo and V, against pure Pt are plotted for different percentages of alloying element, and compared with the usual Pt-Rh or Pt-Ir alloys. Some properties of Pt-Re with up to 10% Re are shown. Brinell hardness rises from 40 for Pt to 180 for the 10% Re alloy. An 8% Re, Pt-Re alloy has an e.m.f. of 35 m.v. at 1300° C. against Pt, or over twice that of the usual thermocouple. One of 4½% Re, 5% Rh, has 30 m.v. at 1300°C. A couple of Rh vs Rh — 8% Re, though giving but about 7 m.v. at 1800° C., is usable up to 1900° C. Loss of weight on heating at 1300° C. is rather high in the 8% Re alloy, but not bad in the 4½% Re, 5% Rh alloy. Cu-Ni, Cu-Ni-Fe, Cu-Ni-Mn-Fe, Ni-Cr, and Ni-Cr-Fe elements are dealt with. A couple of 12.5% Ni, 87.5% Cu vs 20% Ni, 80% Cu has nearly the same e.m.f. as the standard Pt — Pt-Rh couple. Segregation in Ni-Cr and Cu-Ni ingots is discussed. HWG (28)

Some Studies in Pyrometry and on the Radiation Properties of Heated Metals. R. HASE. *Proceeding Physical Society*, London, Vol. 43, Mar. 1, 1931, pages 212-216.

In measuring the spectral energy radiated by solid and liquid metals at high temperature ideal black body conditions are seldom existent so that some sources of error in the methods of pyrometric measurements must always be expected. The conditions are discussed and some experiments described which were made to find the degree of agreement of measurement and values required by theory. Ni and Pt were among the metals used in the experiments. Ha (28)

Pyrometers in Blast Furnace Practice. CHARLES E. FOSTER. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 141-147, 153.

A rather complete discussion of the various types of instruments available for the measuring of temperatures about a plant. The advantages and disadvantages of the instruments are set forth, together with a recommendation of the maximum temperature to which each type should be subjected. Expansion thermometers, electrical pyrometers, resistance pyrometers, thermo-electric pyrometers, and optical and radiation pyrometers are considered. CHL (28)

Remote Control of Voltage Regulators of Plating Baths. (Fernsteuerung von Spannungsreglern galvanischer Bäder.) HUETTER. *Oberflächentechnik*, Vol. 9, Feb. 16, 1932, page 33.

The voltage of the galvanizing generator can be regulated by a magnetic regulator on the machine which is operated by a push-button on each bath so that a change in voltage due to change in load can be compensated directly. Ha (28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Effect of Temperature on the Properties of Nitrided Alloys. OSCAR E. HARDER (Battelle Memorial Institute). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 631-657.

For abstract of paper see *Metals & Alloys*, Vol. 2, Oct. 1931, page 231. In the discussion additional short-time test data are tabulated on an alloy containing 0.30% C, 0.42 Mn, 0.09 Si, 0.67 Ni, 1.21 Cr, 1.31 Al, and 0.18 Mo. The tests made up to temperatures of 1400° F., were on a specimen of 0.253" diameter. A total of 180 hours' treatment produced a 1/16" case, comprising approximately ½ of the total cross sectional area. Nitrided bars show greater strength, yield point and proportional limit at the high temperatures than is obtained on the heat treated unnitrided material. On the other hand, from 70° up to 800° or 900° F. the strength properties of the nitrided bars are shown to be decidedly inferior. A comparison is made of the modulus of elasticity up to 1000° F. on nitrided and unnitrided material. WAT (29)

Nickel and Nickel Alloys Other Than the Nickel-Chromium-Iron Group. C. A. CRAWFORD & ROBERT WORTHINGTON (International Nickel Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 557-588.

For abstract of paper see *Metals & Alloys*, Vol. 2, Sept. 1931, page 192. In the discussion additional short-time test data are tabulated and shown graphically on admiralty nickel (70 Cu, 29 Ni, 1 Sn) and compared with Monel metal (70 Ni, 30 Cu) between 70° and 1400° F. WAT (29)

Thermal Conductivity of Tin at Low Temperatures. W. J. DE HAAS, S. AYOAMA & H. BREMMAR. *Proceedings Academy Science, Amsterdam*, Vol. 34, Jan. 31, 1931, pages 75-77.

Experiments were made on a rod of pure Sn, 9 cm. long and 1.8 mm. in diameter at 9 temperatures between 97° and 12.5° K. The energy input was measured electrically and the temperatures were measured with a gas thermometer and a Pt resistance thermometer. Because of the indefinite form of the contacts at the extremities of the rod, the values of the coefficient of thermal conductivity in absolute units could not be calculated accurately. Results are given for the "thermal resistance" of the rod. This decreases steadily as the temperature is lowered and the value at 12.5° K is less than ¼ that at 97° K. The curve has a point of inflection at about 15° K and agrees essentially with the results of Gruneisen and Goens. WHB+WAT (29)

On Crystal Deformations under Large Pressures and Elevated Temperatures. (Ueber Deformationen an Kristallen bei erhöhtem Druck und erhöhter Temperatur.) F. HEIDE (University of Jena) *Zeitschrift für Kristallographie*, Vol. 78, June 1931, pages 257-278.

A testing equipment designed for the study of crystals exposed to large pressures (19,000 atmospheres max.) and to elevated temperatures (430° C. max.) is described. EF (29)

The Effect of Temperature on Some of the Physical Properties of Metals. F. C. LEA & C. F. PARKER. *Engineering*, Vol. 133, Jan. 1, 1932, pages 23-26; Jan. 8, 1932, pages 54-55; *Engineer*, Vol. 152, Oct. 2, 1931, page 255 (abstract).

The object of the research is to consider the phenomenon and methods of measuring creep in relation to temperature and stress. The authors have used two methods for determining creep, (1) in which a specimen is subjected to either tension or compression, more generally the former, and (2) the specimen is subjected to a constant torsional stress. Diagrams of the apparatus are included, as well as a detailed description of the test methods. The steel studied was one containing 0.45% C, 14% Cr, 9% Ni, and 3.5% W. The temperatures of test were room temperature, 475°, 500°, and 610° C. The results of short-time tension tests, creep tests, and a special torsional-creep test are presented in tabular as well as graphic form. Izod impact values and Vickers hardness values are also given between the temperatures of 20° and 700° C. for the alloy steel and three low carbon low alloy steels. At temperatures above 500° C. mild steels not only show a low "limiting creep stress" or a low stress for 10^{-7} in./in./hr. creep, but they show a considerable tendency to intercrystalline corrosion and oxidation of the pearlitic areas, and consequently distinct changes in impact values at room temperature. With the special alloy steels that are now being made, the risk of scaling and intercrystalline corrosion at 500° C. is reduced to a minimum, but continuous creep may take place in shear at 500° C. at stresses of 2 tons/in.^{2}, corresponding to simple tensile stress of 4 tons/in.^{2} LFM + WAT (29)

Thermal Expansion of Metals. NORMAN L. MOCHEL. (Westinghouse Electric & Mfg. Co.). *Symposium on Effect of Temperature on Metals, A.S.T.M.—A.S.M.E. Joint Research Committee*, 1931, pages 683-724.

For abstract of paper see *Metals & Alloys*, Vol. 2, Oct. 1931, page 232. In discussion from the Detroit Edison Company is emphasized the fact that the engineer should not be called on to convert expansion coefficients or other constants from the metric into the English system. The physicists in compiling the data should set forth the constants in terms the engineer could readily use. Expansion coefficients should be tabulated both in Centigrade and Fahrenheit temperatures. The National Fire Protection Association states that more attention should be given to the effect of fires and conflagrations upon structural steel and other metals employed in the construction and found among the contents of buildings and other structures that may be exposed to accidental fire. It is suggested that unequal expansion during a fire may cause more damage than loss of strength. In considering some of the so-called heat-resistant alloys for building purposes, it appears well to point out that many such alloys have considerably higher rates of expansion than ordinary steel, and that although increased strength might be attained by their use the problem would be much aggravated by their increased rate of expansion. WAT (29)

Effect of Elevated Temperatures on Certain Mechanical Properties of Gray Cast Iron and Malleable Iron. J. W. Bolton (Lunkenheimer Company) & Hyman Bornstein (Deere and Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 436-465.

For abstract of paper see *Metals & Alloys*, Vol. 2, Sept. 1931, page 192. In the discussion the Crane Company states that up to 750° F. there is no measurable growth in cast iron. The range between 750° and 900° F. is apparently where growth commences. The Worthington Pump and Machinery Corporation in the discussion presents data obtained at Battelle Memorial Institute on short-time tensile and long-duration creep tests on 3 cast irons, a gray iron, a high-test iron (2.5% Si) and a Ni iron (1.5% Ni). In the short-time tests, reported to 1500° F., the three irons hold their original strength well up to 700° F. At this temperature the high-test iron shows superiority, having about 50,000 lbs./in.^{2} tensile strength. The Ni iron follows with a strength of about 45,000 lbs./in.^{2} and the gray iron next with about 35,000 lbs./in.^{2} at 700° F. In the creep tests at 700° F. and under a load of 10,500 lbs./in.^{2} the deformation rate slowed down almost to zero well before 2000 hours had elapsed on the high test and Ni irons and the curves presented show that the gray iron had also slowed down almost to zero; the creep rate on the latter iron being of the order 0.0000003 in./in./hr. After 2015 hours under load at 700° F. the bars were removed from the creep test apparatus and subjected to tension tests at room temperature. There was practically no change in the tensile properties. The Brinell hardness had been reduced from the original value about 6% for the high-test and Ni irons, and about 20% for the gray iron. Thermal expansion data on these irons are also presented. The coefficient of expansion per ° F. between 100° and 1000° F. for all three irons is the same, namely 0.0000076. (As far as the abstractor is aware this is the most complete collection of data on the short-time tension and creep characteristics of cast irons at elevated temperatures available in the published literature). WAT (29)

On the Influence of Temperature on the Elastic Behaviour of Various Wrought Light Metal Alloys. Franz Bollenrath (Aerodynamisches Institut, Technische Hochschule, Aachen). *Institute of Metals, Advance Copy* No. 588, Apr. 1932, 14 pages.

Strong Al and Mg alloys were tested at temperatures between —190 and +180° C. All were wrought, and were tested in tension. Extreme care was used in maintaining the specimens at the desired temperature during testing. All specimens were held at the testing temperature for 110 hr. before testing in order that no further changes in the structure would take place during testing. Round specimens 10 mm. in diameter with a 100 mm. gage length were used. Elongation was measured with a Martens optical extensometer. The modulus of elasticity decreased regularly with increasing temperature in some alloys, but maximum values were observed at room temperatures in Silumin and Lautal. It is suggested that the Si causes the maxima in these curves. The moduli for the various alloys at 20° C. were:

Alloy	Modulus of Elasticity kg./mm.^{2}
Duralumin 681 B	7050
Duralumin 681ZB	7180
Scleron	6880
Silumin	6650
Constructal 2	6950
Constructal 87	7100
Elektron AZM	4270
Elektron Vlw	4280

Values of elastic limit were also obtained. These values are based on permanent elongations of 0.001, 0.01 and 0.03%. 7 references. JLG (29)

Creep of Steel Under Simple and Compound Stresses and the Use of High Initial Temperature in Steam Power Plant. R. W. Bailey. *Transactions Tokyo Sectional Meeting, World Power Conference*, 1929, Vol. 3, 1931, pages 1089-1121.

Design of plant for high temperature service should be based upon the permissible changes in dimensions and materials. A creep rate of 10^{-8} tensile strain per hour should be considered as a working limit. Structural changes occurring in C steel at present common working temperatures, that is, spheroidization of cementite, are apparently the same as is known to occur at higher temperatures but in less time. Preliminary tests indicate that in a 0.9% C steel spheroidization of cementite reduces the stress for a given rate of creep about 25%. A smaller reduction in stress is to be expected in steels of lower C content. Further research on this is desirable. In order to retard structural changes in boiler parts subjected to strain hardening in manufacturing, annealing of these parts is essential. Oxidation must not be overlooked. Torsion creep tests may be taken to indicate that creep by shear at a plane is uninfluenced by the normal stress acting upon that plane. By means of this hypothesis creep under different straining actions may be correlated. Thin cylindrical tubes under torsion are found to correspond with thin tubes under internal pressure. While there is evidence that creep by shear may be regarded as general, the alternate torsion and tension tests made by the author at 480° and 550° C. indicate that the behavior at these temperatures is different. Deductions made in accordance with the tests upon steel tubes and the hypothesis suggested above, receive confirmation from tests upon Pb pipes under internal pressures. Unless there is superimposed axial stress, pipes, tubes, etc., may be expected to creep only in the direction of the diameter. Any loading upon a steam pipe due to thermal expansion whether giving rise to a direct load or a bending moment, will relieve itself under operating conditions by creep and the stresses corresponding with the full thermal expansion will occur when the system is cold. All these conclusions are illustrated graphically. The torsional creep apparatus is described and illustrated. See also *Metals & Alloys*, Vol. 1, Oct. 1930, page 795. WAT (29)

Measurements of the Electrical Resistance of Pure Indium, Thallium and Gallium at Low Temperatures of the Magnetic Disturbance of the Superconductivity of Thallium. W. J. De Haas & J. Voogd. *Proceedings Academy of Sciences, Amsterdam*, Vol. 34, Jan. 31, 1931, pages 51-55.

Results are given for measurements on several samples of very pure In and Tl at temperatures in the neighborhood of the boiling point of He. Indium becomes supraconducting at 3.37° K and Tl at 2.35° K. For Ga the ratio R/R. is 0.2625 at 90.55° K and 0.00031 at 4.25° K. It becomes supraconducting between 1.07 and 1.05° K. Data are given showing the effect on the supraconducting of Tl of longitudinal magnetic fields ranging from 28.3 gausses to 128.4 gausses. The value of the magnetic field for which, in an increasing field, the resistance is restored to half of its normal value is plotted against temperature and compared with the results of De Haas, Sizoo and Onnes for Hg. While the graph for Hg is straight above 3° K and curved below that temperature the graph for Tl is curved at all temperatures below the transition temperature. WHB+WAT (29)

Heat Resistance of Plain Carbon Steel. (Resistance a Chaud des Aciers Ordinaires.) L. Guillet, J. Galibourg & M. Samsoen. *Aciers Speciaux, Metaux et Alliages*, Vol. 6, July 1931, pages 353-354; *Genie Civil*, Vol. 98, May 2, 1931, page 455.

See *Metals & Alloys*, Vol. 2, Oct. 1931, page 232.
GTM+Ha (29)

Hollow Forged Vessels for High Temperatures and Pressures. Ronald Benson. *Metallurgia*, Vol. 5, Feb. 1932, pages 131-132.

Describes the large forged vessels produced by the English Steel Corp. and methods used in their production. Ingots weighing as much as 170 tons are required. The center is either machined out of the cold annealed ingot or punched from the hot ingot. In the latter case the material is not below a red heat until the forging is completed. Bottle neck ends may be produced by swaging. Either plain C or alloy steels are used. Steels containing Mo have been found to have high creep limits at temperatures between 400 and 500° C. JLG (29)

Heat Emission From Iron and Copper Pipe. F. C. Houghten & Carl Gutberlet. *Heating, Piping & Air Conditioning*, Vol. 4, Jan. 1932, pages 47-52.

Data are presented on the heat emission from bare Fe and Cu pipe under service conditions at various temperatures resulting from a study made at the Research Laboratory of the American Society of Heating and Ventilating Engineers in coöperation with the Associated Copper Tubing Manufacturers. A few data are included giving heat emission for galvanized Fe, brass and Al pipe, and the effect of paint on the surface of the pipe on the rate of heat emission, and the reduction in heat emission from standard iron pipe resulting from the application of commercial insulation. The heat loss from bare Cu pipe is approximately 54% of the loss from bare black Fe pipe of the same nominal size, and 203% of the loss from Fe pipe covered with 4-ply air cell insulation. The heat loss is approximately the same for horizontal and vertical pipe of the same size and material. WAT (29)

Effect of Low Temperatures on Metals and Alloys. H. W. RUSSELL, (Battelle Memorial Institute). *Symposium on Effect of Temperature on Metals, A.S.T.M.—A.S.M.E. Joint Research Committee,* 1931, pages 658-682.

For abstract of paper see *Metals & Alloys,* Vol. 2, Nov. 1931, page 283. In the discussion several exceptions are taken to the conclusions and generalizations made in the paper. In certain metals and alloys (Cu, Al, and Ni and some of their alloys) it is quite reasonable to expect increased ductility or toughness or both to accompany the increased hardness produced by the lowered temperature, rather than a decrease as stated in the paper. Additional short-time test data are tabulated on cold rolled Cu, Ni, naval brass, nickel silver, annealed nickel silver, and forged aluminum bronze at boiling liquid air temperature and room temperature. A probable relation in carbon and low-alloy steels between microstructure and change in elongation and reduction of area upon lowering temperature is indicated. In boiling liquid air these changes with heat treatment are occasionally large. WAT (29)

High Pressure Steam. F. H. ROSENCRANTS. *Transactions Tokyo Sectional Meeting, World Power Conference,* 1929, Vol. 3, 1931, pages 873-897.

Reviews the present stage of development of steam generation and utilization, with particular reference to increased pressure and temperatures, and points out that although a number of noteworthy installations are operating at pressures and temperatures far in advance of normal practice, no uniformity of opinion yet prevails as to the economic advantages that are being realized. It is pointed out that advantages in temperature are limited by the physical characteristics of the materials of construction. Above a temperature of 750° F. a field is entered where preconceived ideas of stress, usually adopted by designers, are no longer valid, due to the phenomenon of creep taking place in all materials maintained at high temperatures. This condition lowers considerably the safe working stress. A lessening interest is predicted in high pressure and further progress in the direction of temperature. Limiting creep stresses and elastic moduli values are compared graphically for Armco Fe and various C steels for temperatures up to 1000° F. WAT (29)

The Effect of Temperature on Some Properties of Iron-Chromium-Nickel Alloys. N. B. PILLING & ROBERT WORTHINGTON (International Nickel Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.—A.S.M.E. Joint Research Committee,* 1931, pages 495-556.

For abstract of paper see *Metals & Alloys,* Vol. 2, Oct. 1931, page 231. In the discussion the statement is made that the terms "18-8" and "35-15" as applied to Ni-Cr alloys are meaningless so far as indicating the probable performance of a specific sample under given conditions. Elements such as C, Si, and Mn exert profound influence upon the character of the alloy and its performance in practical service. It is to C and Si that cast iron owes its superiority to mild steel in heat resistance and corrosion resistance. Mn also affects the strength and corrosion resistance. There is, however, an optimum quantity of these three elements in combination with Ni and Cr that produce the most satisfactory results. The wide variation in results reported by different investigators on supposedly the same material is probably due to some extent to the lack of control the less predominant elements in the melting furnace. In another discussion it is stated that the use of heat-resisting alloys would be increased tremendously if it were possible to use thinner sections in castings. The very large factor of safety necessary in some sections undoubtedly makes these parts too heavy. Much of the existing data on the properties of metals at elevated temperatures is of questionable utility, principally because of incomplete information regarding the history of the material prior to testing. It is strongly urged that sponsor societies set up through their various committees standardization of test bar preparation, standardization of test methods and systems of checking reliable short-time proportional limit data against long-time creep data. Further tests should be developed to indicate the relative cleanliness of cast alloys. The general opinion of the majority of the discussers seems to be that the paper indicates certain prominent gaps in the present knowledge of the high-temperature behavior of alloys. More information is needed on the properties of castings at higher temperatures, and on the effects of corroding media, other than oxygen, in these high temperature ranges. Short-time tension test data are tabulated for an alloy of 80% Ni, 13 Cr, 6 Fe, 0.12 C, 1 Mn, 0.01 Cu and S and 0.1 Si between the temperatures 70° and 2200° F. WAT (29)

Accidents to Water Tube Boilers in Service (Les accidents de tubes de chaudières aquatubulaires en service). GASTON PARIS. *Chaleur et Industrie,* Vol. 138, Oct. 1931, pages 507-516.

The question of materials for the construction of boilers has, in recent years, received considerable attention. Not only has there been a call for the study of the qualities of the resistances of these materials to temperatures and pressures, but metallurgical problems have been raised that have not met the satisfactory approval of every one. It is more particular, above pressures of 88 lbs. that super-heat temperatures of 450° C. are theoretically used. But in actual service, it is not known how metals resist for very long times, and with absolute safety a temperature of super-heat of 500° to 550° C. Also for pressures of the order of 220 lbs. it is necessary to limit the temperature of super-heat to 440° C. It is also a matter of considerable importance that research produce metals having the necessary qualifications and not have a price that prohibits their use. For many years, binary and ternary alloys have been susceptible to oxidation when used for super-heater tubes, in the presence of gases at a temperature of 500° C. For this reason, many metals have been rendered unsatisfactory. The problem is not limited to boiler tubes. Piping and valves must also resist high temperatures. In different degrees, the same question is what metals should constitute boiler materials. The researches of Babcock and Wilcox are reviewed, and a number of typical examples of boiler corrosion and oxidation are presented in photographs and micrographs. WAT (29)

Chromium Steels for High Heat Resistance. (Ein Beitrag zur Kenntnis Hoch Hitzebeständiger Chrom Stähle.) MAX SCHMIDT & OTTO JUNGWIRTH. *Archiv für Eisenhüttenwesen,* Vol. 5, Feb. 1932, pages 419-426.

The applicability of high heat resistant steels, in range of 700° to 1300° C. is shown by their resistance to ignition loss, strength and tenacity under heat, mechanical stability during continuous work at elevated temperatures, and price. 17 different steels, Cr 18-32%, C 0.12%-1.72%, and varying proportions of Mo, W, Co and V were studied. The behavior of these steels on continuous work at elevated temperatures is shown to be of especial importance and differences are to be noted between cast and forged materials. In the forged state, the steels with 22% Cr and approximately 0.3 to 0.55% O_2 give best results up to 1000° C., while above this temperature the tenacity of all tested specimens is lost rather quickly; small additions of W, Mo, V and Co produce no advantages in this respect. In the cast condition temperatures above 1000° C. do not cause unfavorable results, and at 1100° C., under repeated annealing the bend resistance actually increases. The structure of 22% Cr-steels was thoroughly studied and practical behavior of these steels is explained by the type of structure. In the application of heat resistant steels in forged state, temperature limits of continuously worked material were determined, while with cast metal, resistance towards ignition loss is given. Steels containing 30% Cr are preferable for cast parts, while for forged pieces, steels with 22% Cr appear to be better. Numerous diagrams and data compiled to illustrate results. DTR (29)

The Hardness of Metal Alloys at Different Temperatures. Die Härte der Metallegierungen bei verschiedenen Temperaturen.) W. SCHISCHOKIN & W. AGEJEWA. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 193, Oct. 21, 1930, pages 237-244.

The relation of the temperature coefficient of the hardness of those binary systems which do not form intermetallic compounds was investigated; from the measurements on Bi-Sn, Bi-Cd, Pb-Cd, Sn-Cd, Pb-Zn, Sn-Zn and Zn-Cd, the curve of the temperature coefficient at different temperatures of the hardness could be represented by the equation

$$a = \frac{\log H_2 - \log H_1}{t_2 - t_1}$$

where H_2 and H_1 are the values of hardness at temperatures t_2 and t_1 respectively. In all systems, except Sn-Cd, the eutectic alloy has highest temperature coefficient. Ha (29)

Copper Embrittlement. L. L. WYMAN (General Electric Co.). *American Institute Mining & Metallurgical Engineers, Preprint,* 1931, 11 pages.

Embrittlement of various coppers resulting from heating in an oxidizing atmosphere followed by heating in a reducing atmosphere was studied. A number of temperatures for both atmospheres were used. The coppers investigated included: tough pitch, vacuum melted, and those deoxidized with calcium boride, Si, Si plus P, and Zn. Sheets 0.060 in. thick were used, and the embrittlement was followed by microscopic examination. The coppers were rated in the following order with respect to their resistance to embrittlement: Zn deoxidized, Si deoxidized, calcium boride deoxidized, vacuum treated, Si and P deoxidized, and tough pitch. There were many variations in materials that had supposedly received same deoxidizing treatment. 9 references. JLG (29)

The Selection and Testing of Materials for Highly Stressed Chemical Apparatus. (Die Werkstoffrage und Werkstoffprüfung bei hochbeanspruchten Chemischen Apparaten.) ERNST FRANKE. *Die Chemische Fabrik,* Vol. 4, Mar. 25, 1931, pages 133-135.

Steel used for chemical apparatus must not become brittle after aging, must retain its strength at elevated temperatures, must not corrode easily and must be free from caustic embrittlement. Among steels which meet these requirements are Izett steel, low C-V or Mo cast steel and 3-5% Ni steels. When a stronger steel is used for construction the sections can be correspondingly reduced. Metals used for chemical apparatus should be thoroughly tested. In addition to the usual tests impact tests before and after artificial aging should be made. The aging consists of a 10% cold reduction followed immediately by heating to 250° C. for ½ hour. The difference in impact due to aging should be slight. Long time tensile tests at elevated temperatures and creep limit determinations should also be made. High grade testing machines are required for making these tests. CEM (29)

Magnetic Disturbance of the Superconductivity of Single-Crystal Wires of Tin. W. J. DE HAAS & J. VOOGD. *Proceedings Academy of Science, Amsterdam,* Vol. 34, Jan. 31, 1931, pages 63-69.

Single crystals of Sn approximately 15 mm. long and from 0.15 to 0.25 mm. in diameter were studied at low temperatures, in both transverse and longitudinal magnetic fields. The results in general resembled those previously observed in Hg. That is (a) there is a hysteresis effect in that the resistance reappears at a higher value of the magnetic field than that for which it disappears as the field is reduced; and (b) there are discontinuities in the resistance-magnetic field curve. At 2.92° K when the field is applied longitudinally it is possible to observe a transition state between the normal resistivity and the supraconductivity as the field is increased, but the resistance vanishes abruptly as the field is diminished. This vanishing does not always occur at the same field intensity, but the value is always less than the field for which the resistance appears. At 2.89° K when the field is applied transversely, the effects are quite different. A gradual increase in field produces a gradual increase in resistance, starting at H = 64 gausses, and becoming constant at about H = 102 gausses. Increasing H to 214 gausses produces no appreciable change in resistance. As H is decreased, the resistance remains constant until H is approximately 95 gausses, when the resistance vanishes abruptly. The exact values in the transverse effect depend to some extent upon the current used in measuring the resistance, but the longitudinal effect seems to be independent of the current strength within considerable limits. The character of the magnetic transition figure seems to be independent of the orientation of the crystal axis with respect to the axis of the wire. A graph is given showing the effect of temperature on the field intensity at which the resistance is restored in the longitudinal effect. WHB (29)

The Temperature Shift of the Transmission Band of Silver. J. V. Pennington. *Physical Review,* Vol. 39, Mar. 1932, pages 953-956.

It is shown that by Kronig's quantum theory of dispersion in metals the shift of the frequency at which maximum transmission is found for Ag when the temperature is varied from -269° to +254° C. can be explained. The calculated rate of shift is in agreement with experiment. WAT (29)

Determinations of the Creep Characteristics of Metals on Heating (Sur la dètermination des caractéristiques d'allongement visqueux des métaux à chaud). Georges Ranque & Pierre Henry. *Genie Civil,* Vol. 99, Dec. 1931, pages 630-631; *Comptes Rendus,* Vol. 193, Nov. 1931, pages 1061-1063.

An accelerated creep testing apparatus similar to that developed by Rohn (See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 27) has been constructed and the creep characteristics of Armco iron have been determined according to the three following methods; (1) measuring as a function of time the decreasing load required to maintain constant elongation under constant temperature, (2) measuring as a function of time the elongation under constant load and temperature, and (3) measuring as a function of time the temperature at which no creep occurred under constant load. A diagram and description of the apparatus is presented. Elongations of 1.58% at 550° C., 0.65% at 475° C. and 0.003% at 400° C., under a load of 6 kg./mm.^{2}, are reported for Armco iron based on a creep rate of 0.005% per 100 hours and extrapolated to 10,000 hours. OWE+WAT (29)

A Photographic Creep Testing Apparatus. D. A. Roberts & R. L. Dowdell (Univ. of Minnesota). *Metals & Alloys,* Vol. 2, Dec. 1931, pages 349-351.

The authors describe apparatus for creep testing in which the creep is recorded photographically. 2 Pt gage wires are attached to the specimen 2" apart. To one of the gage wires, a Pt strip 3/16" wide bent to conform to the contour of the test specimen is attached; the strip is 2" long and the gap between it and the other gage wire is periodically photographed with suitably arranged camera. The Pt strip is embossed with lines a definite distance apart for determining the magnification of any particular photograph. Lantern slide negatives of the gap allow, by projection on a screen, any desired magnification of the creep. The claims for the apparatus are that it takes a creep measurement directly on the specimen without effect of deflection in other parts of the equipment and without effect of heat. The record is permanent and free from personal error and is capable of any desired degree of accuracy. WLC (29)

Tensile Properties of Rail Steels at Elevated Temperatures. G. Willard Quick (U. S. Bureau of Standards). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 25 pages; *Bureau of Standards Journal of Research,* Vol. 8, Feb. 1932, *Research Paper* 408, pages 173-189.

Tensile tests at temperatures up to 700 or 750° C. were made on 28 specimens of new and used rails from 18 different heats. The materials represented differences in composition and different rates of cooling on the hot beds. It was found that the secondary brittleness at 400-700° C. was an inherent property of rail steel. It is suggested that slow cooling through the secondary brittleness range improves the ductility of rails. New and used rails containing shatter cracks were examined, and there was some indication that shatter cracks were nuclei for transverse fissure formation. There was no appreciable difference in strength or ductility at elevated temperatures between transverse-fissured rails and rails that had been subjected to the same service without fissuring. Sorbitic rails had marked secondary brittleness. Medium Mn rails also had a pronounced secondary brittleness. 3 references. JLG+WAT (29)

High Temperature Resistor Uses Iron-Base Alloy. Correspondence from E. Oehman, Stockholm, Sweden. *Metal Progress,* Vol. 20, Dec. 1931, page 78.

The writer describes the heat resisting properties of an iron base alloy, which is marketed under the name of Kanthal, containing Cr, Al and Co which has a melting point of 3000° F. and resists scaling up to 2400° F. Resistance is 15-20% higher than best Ni-Cr alloys. Furnace element run 500 hrs. at 2375° F. and subjected to a maximum temperature of 2450° F. showed no deformation and only slight oxidation. WLC (29)

The Resistance to Impact of Rail Steels at Elevated Temperatures. G. Willard Quick. *Bureau of Standards Journal of Research,* Vol. 8, Feb. 1932, *Research Paper* 409, pages 191-198; *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 10 pages.

Charpy impact tests were made in the temperature range 20° to 700° C. on V notch specimens cut transversely and longitudinally from a medium Mn rail, and on longitudinal specimens cut from 2 standard rails, one cooled normally and the other slowly after leaving the hot saw, 2 heat-treated rails and 1 untreated comparison rail, and a commercial bar stock steel containing 0.60 % C. The energy absorbed in breaking the specimens from all these materials increased as the temperature increased from 20° to about 400° C., then decreased to a minimum at about 600° C., after which it increased rapidly to 700° C. Tensile tests on the rail steels, reported previously, had shown a marked decrease in elongation and reduction of area for all of the rail steels between 400° and 700° C., with the minimum values at 550° or 600° C., but not for the bar stock. The tensile test had also shown somewhat higher ductility in the secondary brittle range for the slowly cooled rail and the heat-treated rails than for the normally cooled and the untreated comparison rail, but the impact test did not distinguish between them. The path of the fractures in the impact specimens was transcrystalline at all temperatures. It is believed that the minimum values for impact strength occurring at 550° or 600° C. may be ascribed to the same phenomenon as the low ductility disclosed by the tensile tests at the same temperatures, namely, that of secondary brittleness rather than to the phenomenon of blue brittleness which some believe occurs at a higher temperature in dynamic tests than in tensile tests. WAT+JLG (29)

Some Physical Properties of Wiping Solders. D. A. McLean, R. L. Peek & E. E. Schumacher. *Bell Telephone System Technical Publications,* Monograph B-641, 1932, 25 pages.

The plasticity of a number of solders at wiping temperatures has been determined by compression tests between parallel plates. The character of the flow is found to be that corresponding to a linear relation between shearing and a fractional power of the velocity gradient. This corresponds approximately to a relation between rate of compression (dh/dt) and sample height (h) given by the equation: $dh/dt = kh^b$, in which K and b are constants, of which b is independent of the test conditions. For viscous materials b = 5.0; for most solders b is greater than 5.0, and increasing values of b are associated with the lower temperature gradients of plasticity. It is shown that a solder must have a low temperature gradient of plasticity in order to be properly wiped, and that determination of the value b by means of a plasticity test can therefore be used to evaluate the working properties of a solder. A number of factors upon which the plasticity of wiping solders and the porosity of wiped joints may depend have been investigated. In particular, it is shown that segregation is not responsible for porosity, but that the latter may be dependent upon the particle size of the solid phase at wiping temperatures. The relation of particle size to the wetting power of the liquid phase is discussed. WAT (29)

High-Chromium Steels for Extreme Service Conditions. C. E. MacQuigg (Union Carbide and Carbon Research Laboratories). *Symposium on Effect of Temperature on Metals, A.S.T.M.—A.S.M.E. Joint Research Committee,* 1931, pages 589-609.

For abstract of paper see *Metals & Alloys,* Vol. 2, Oct. 1931, page 231. In the discussion it is emphasized that steels containing 4-6% Cr have given satisfaction in oil still tubes where excellent resistance has been offered to the high-sulphur crude oils, notably in the Texas fields. Additional short-time test data are tabulated for a steel containing 0.17% C and 5.44 Cr. These results indicate a yield point of approximately 65,000 lbs./in.^{2} at 1200° F. Steels in the group of 4-6% Cr show marked plastic yielding before failure. This ability to "hang on" in service gives ample warning to avert accident. These steels also have air hardening properties. This characteristic, however, while sometimes of advantage presents difficulties in flanging, welding and similar operations. The addition of W and Mo promises to benefit the creep resistance of such steels. WAT (29)

Resistance of Steels to High Temperatures. (La Résistance des Aciers aux Températures Élevées). André Michel. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Nov. 1931, pages 536-546.

A general review of present status of knowledge on the properties of steels in service at high temperatures. GTM (29)

The X-Ray Examination of Aluminum at High Temperatures. A. J. Alichanow. *Zhurnol Prikladnoi Fiziky,* Vol. 6, 1931, pages 19-22.

Al was investigated with X-rays in order to test whether it showed an allotropic transformation between the temperatures 575° and 600° C. It was found that its structure, being that of a face-centered cube, remained unchanged. Thus far the same line system was observed independently of the previous treatment, but no measurements had been made at the higher temperatures. See also *Metals & Alloys,* Vol. 1, Aug. 1929, page 75. WAT (29)

Red Shortness of Steel in Contact with Other Metals. H. Schottky, K. Schichtel & R. Stolle. *Iron Age,* Vol. 128, Dec. 24, 1931, page 1607.

An abstract translation of an article in *Stahl und Eisen,* Vol. 51, June 18, 1931. A description is given of the development of red shortness in steels of 0.10-1% C. at temperatures of 1500°-2200° F. as influenced by contact with other metals. Comparisons are made by hot-bend tests with the powdered contact metal distributed over the tension side of the specimen. In general, metals causing red shortness are completely miscible with iron in the liquid state, but have limited solubility in solid iron. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 193. VSP (29)

Effect of Temperature upon the Charpy Impact Strength of Die-casting Alloys. Bert E. Sandell (Stewart Die Casting Corp.). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 4 pages.

Made Charpy impact tests on 2 Zn-base alloys and 2 Al-base alloys at temperatures from 0 to 500° F. Standard A.S.T.M. specimens were used. The Zn alloys contained 4% Al, 3% Cu and 0.1% Mg. One set represented present practice and the other set a prior practice. The Al alloys contained 5 and 11.5% Si. The impact strength of the Zn alloys varied with the temperature. They were brittle at low temperatures and became less brittle as the temperature rose. The alloys representative of present practice had higher values at all temperatures. No appreciable variation in impact resistance was found in the Al alloys in the temperature range investigated. JLG (29)

Apparatus for Low-temperature Endurance Testing. H. W. Russell & W. A. Welcker, Jr. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 1, 1931, pages 122-128.

General review. AHE (29)

Note on Applications of Data on the Thermal Conductivity of Metals. M. S. Van Dusen (Bureau of Standards). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, 725-733.

For abstract of paper see *Metals & Alloys,* Vol. 2, Oct. 1931, page 203. In the discussion there is given from the Bureau of Standards a graph showing the change in thermal conductivity with increase in temperature to 600° C. for chemically pure (99.95%) Zn, graphite, high-purity (99.94%) Ni, malleable (99+%) Ni, gray cast iron, eutectoid steel, 1% W steel, high-purity (99.9%) Pb, 15% Cr steel, 17% Cr steel, 1.5% Al steel and a 12% Mn—3% Ni steel. The conductivity of these materials as compared with each other decreases in the order listed. WAT (29)

MANUFACTURERS' LITERATURE REVIEWS

436 **Deoxidizers for Steel**—Bulletin SM-1 of the Electro Metallurgical Co., New York, N. Y., describes the deoxidation of steel with silicon-manganese alloys, its mechanism and practical applications.

437 **Instruments for Spectrographic Analysis**—A 45-page booklet compiled by the Bausch & Lomb Optical Co., Rochester, N. Y., gives general information on quartz spectrographs, spectrography in the analytical laboratory, sector photometry and a description and prices of their instruments.

438 **Cadmium Plating**—The July 1932 issue of Udylite News, published by the Udylite Process Co., Detroit, Mich., contains a full description and illustrations of the new Udylite laboratories. A pamphlet published by the same company describes their new plating barrel with hard rubber cylinder.

439 **Stainless Steel Motor**—A leaflet published by the Lincoln Electric Company, Cleveland, Ohio, is devoted to their Stainless Steel, Type E Induction Motor. Construction features are given.

440 **Relays**—Leaflet GEA-1583 issued by the General Electric Co., Schenectady, N. Y., is given over to a discussion of their electric relays. A few types are listed and described.

441 **Grinding**—The June issue of Grits & Grinds, published by the Norton Co., Worcester, Mass., features an article entitled "Cylindrical Grinding of Hollow Work—Tubes, Pipes."

442 **Enamels**—A leaflet discussing their acid-resisting enamel for sheet metal as well as cast iron has been issued by the Ferro Enamel Corporation, Cleveland, O.

443 **Electric Furnaces**—The Pittsburgh Electric Furnace Corp., Pittsburgh, Pa., has sent out reprints of an article entitled "The Manufacture of Acid Electric Steel and Cast Iron." Two interesting bulletins issued by the same company are, G1—The 'Lectromelt Process for Gray Iron Castings and SC—The 'Lectromelt Process for making Steel Castings.

444 **Hot Strip Reels**—Bulletin N-301 of the United Engineering & Foundry Co., Pittsburgh, Pa., presents a survey of the best available machines for the reeling, coiling, winding, re-winding, re-coiling and coil-opening of hot-rolled metal strips.

445 **Dowmetal**—The Dow Chemical Co., Midland, Mich., has prepared a number of data sheets giving the composition and uses of their magnesium alloys, their mechanical properties and the sizes in which bars, angles, channels and tees of these alloys can be furnished. The sheets are punched for binding.

446 **Wire Cloth**—Catalog No. 32 of the Newark Wire Cloth Co., Newark, N. J., is practically a handbook on wire cloth containing 100 pages of information on the subject. Wire cloth of stainless steel, Monel metal, nickel, copper, bronze, manganese steel, silver, gold, platinum, etc., are listed. A novel feature is a glossary of wire cloth terms.

447 **Steel**—A new issue of the Ryerson Journal and Stock List has just been published by Joseph T. Ryerson & Son, Chicago, Ill. This handy reference book on steel, in addition to complete general descriptions, specifications, sizes, etc., contains the new extras on bands, the new cold finished steel extras, the new hot rolled cutting extras, and other information of value to the steel user.

448 **Forge Furnaces**—A recent circular sent out by the Surface Combustion Co., Toledo, Ohio, discusses the application of diffusion combustion to forging operations. Descriptions and operating data are given.

449 **Beryllium**—The Brush Laboratories Co., 3715 Euclid Ave., Cleveland, Ohio, has recently issued a price list covering beryllium compounds furnished by them.

450 **Everdur**—A pamphlet prepared by the American Brass Co., Waterbury, Conn., is devoted to their Everdur metal, a high strength weldable material, as applied to rust-proof tanks. It gives the properties and characteristics of Everdur and the capacities of Everdur tanks of various dimensions.

451 **Seamless Pipe**—The National Tube Co., Pittsburgh, Pa., has sent out a price list of their 4%-6% chrome seamless pipe and still tubes.

METALS & ALLOYS, 3619 Forbes St.,

ALPHABETICAL INDEX TO ADVERTISERS

452 **Cold Strip Reels**—Bulletin P 203 issued by the United Engineering & Foundry Co., Pittsburgh, Pa., is devoted to their cold strip reels for the reeling, coiling, winding, blocking, rewinding and uncoiling of cold-rolled metal strips in rolling mill work, from flat wires and narrow ribbons up to the widest sizes, tension from 100 lbs. to over 100,000 lbs.

453 **Arc Welding**—The Hobart Brothers, Troy, Ohio, have issued a leaflet describing their portable welder and power plant combined.

454 **Better Castings**—The August issue of this bulletin of the Niagara Falls Smelting & Refining Corp., Buffalo, N. Y., contains paragraphs discussing their special pattern aluminum alloy, their nickel shot for grey iron, and several alloys of nickel and chromium with grey iron.

455 **Electric Immersion Units**—Leaflet TB-30 issued by the Harold E. Trent Co., Philadelphia, Pa., gives the prices of the various types of electric immersion units for heating liquids, waxes, etc.

456 **Furnaces**—The Ajax Electrothermic Corp., Trenton, N. J., is distributing two reprints of articles which appeared recently. One is entitled "Four Ton Coreless Induction Furnace Installed" and gives a description of the installation and operation of a 4-ton Ajax-Northrup coreless induction furnace. The other, "Vacuum Casting," describes a special adaptation of the use of the high frequency induction furnace for melting and pouring metals under vacuum.

457 **Bearing Metal**—A recent number of the *Dutch Boy Quarterly*, published by the National Lead Co., New York, N. Y., features an article on "Satco," a new and improved bearing metal. Results of tests on this alloy are given, but not its analysis.

458 **Grinding Wheels**—The July-August issue of *Grits & Grinds*, published by the Norton Co., Worcester, Mass., features an article entitled "Judging Relative Merits of Different Wheels for Grinding." Another interesting article in the same issue is "End Surfaces and Flanges Ground with Angular Wheel Slide Grinding Machine."

459 **Arc Welder**—A recent bulletin of the Harnischfeger Corp., Milwaukee, Wis., describes in detail the construction and operating advantages of the P & H-Hansen arc welder manufactured by them. Of particular interest is the description of the "Internal Stabilizer" which eliminates weight and extra equipment and gives an assurance of a more uniform flow of current.

460 **Copper**—Some unusual and interesting applications of copper and brass are described in the July 15th issue of the Bulletin published by the Copper & Brass Research Association, New York, N. Y.

461 **Furnaces**—Bulletin F of the Pittsburgh Electric Furnace Corp., Pittsburgh, Pa., discusses a few of the outstanding features of the Moore Rapid 'Lectromelt furnace. Bulletin GK of the same company gives a description of the operation of a 1½ ton per hour 'Lectromelt furnace.

462 **Electric Belt Conveyor Furnace**—An illustrated 4-page leaflet has been published by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., which describes the applications and uses of this type of equipment.

463 **Stainless Steel Sheets**—An unusually attractive 23-page pamphlet has just been issued by the American Sheet & Tin Plate Company, Pittsburgh, Pa. It discusses the types of stainless and heat resisting steel sheets and light plates manufactured by the company, giving the chemical analysis, physical properties and fabrication of each type. Suggestions for welding stainless steel sheets are given.

464 **Circuit Breakers**—Oil-blast circuit breakers for use on circuits up to 15,000 volts and 2,000 amperes are now available. They are described in leaflets GEA-959D and GEA-1601 sent out by the General Electric Company, Schenectady, N. Y.

465 **Lead**—The September issue of this publication of the Lead Industries Association, New York, N. Y., illustrates a number of interesting applications of lead, among them being a new type of hand wrought lead grilles, lead anti-vibration pads and lead lining for garden pools.

Iron and Steel Metallurgy in 1931. Clyde E. Williams & James L. Gregg (Battelle Memorial Institute). *Mining & Metallurgy,* Vol. 13, Jan. 1932, pages 27-29.

In field of ore concentration attention was given to the more difficultly separated wash ores; some progress made in tabling. Advances made on application of froth flotation to iron ores. Improvements made in automatic control of combustion in open-hearth furnaces. Work of C. H. Herty, Jr. on killed steel was devoted to plant studies of the Bureau of Mines recommended method for deoxidation. The electrolytic method for determining inclusions in steel was developed. Progress made in development and commercial application of high test cast Fe. Most interesting investigations of Fe alloys dealt with alloys that undergo no allotromorphic transformation. Extensive studies made of Fe-Mg alloys of high purity. Embrittlement of structural steels resulted in development of reliable methods for detecting embrittlement. VSP (0)

The Chemical Elements and Atomic Varieties according to the Status of the Isotope Investigations. Report of Investigations from the End of 1930 to the End of 1931. A condensed report of the first lecture of a series before the Society for 1931-32 pictures developments of interest principally to engineers. The work of the Institute at Pittsburgh, Pa. is described in prefacing a discussion of improvements effected in petroleum and rubber products, new uses for by-products, fuel saving, smoke elimination, food supplies, etc. See also *Metals & Alloys,* Vol. 3, May 1932, page MA 115. WHB (0)

A Textbook of Metallurgical Problems. Allison Butts. McGraw-Hill Book Company, Inc., New York, 1932. Cloth, 6 x 9 inches, 425 pages. Price $4.00.

This book fills a very definite need, which no doubt has been recognized by every metallurgical instructor, who used Richard's "Metallurgical Calculations" as a text. In spite of the excellence of Richard's book, metallurgical progress in the ensuing years since the publication of the first edition have disclosed a number of errors and rendered portions of the book obsolete. Butts' book presents a large number of problems designed to accompany courses in metallurgy. It gives examples of methods used in calculation and contains tables supplying the necessary data. Richard Rimbach (0) -B-

PROPERTIES OF METALS (1)

Changes in Electrical Resistance Due to Magnetism and Hardness. S. R. Williams & R. A. Sanderson. *Physical Review,* Vol. 37, Feb. 1931, pages 309-314.

A series of 22 rods or strips of Ni, to which had been imparted different degrees of hardness by cold rolling, had their resistance measured when subjected to a longitudinal magnetic field. There were 11 degrees of hardness, 2 samples for each degree. The longitudinal magnetic field increased the resistance in all cases. The different degrees of hardness did not vary the specific resistance of the Ni, but it did cause a large variation in the change of resistance due to a magnetic field. The measurements were carried out at a constant temperature of 35° C. WAT (1)

The Permeability of Iron, Nickel and Cobalt between 10^6 and 10^7 Cycles. (Die Permeabilität von Eisen, Nickel und Kobalt zwischen 10^6 und 10^7 Hertz.) M. J. O. Strutt. *Zeitschrift für Physik,* Vol. 69, April 13, 1931, pages 632-658.

The tests were made at these frequencies between a few tenths and a few Gauss. In this range, the permeability of the 3 metals decreases slowly with increasing frequency; anomalies as previously assumed to exist at 100 m. wave length could not be confirmed. Heat treatment of the Fe does not show any influence. Ha (1)

On the Conductivity of Thin Metal Foils. (Ueber die Leitfähigkeit von dünnen Metallfolien.) Ladislaus Tisza. *Naturwissenschaften,* Vol. 19, Jan. 23, 1931, pages 86-87.

It is suggested that tests already made on the conductivity of foil should be augmented by others made at very low temperatures, as the critical thickness below which the conductivity decreases very rapidly is much greater at low temperatures than at room temperature. WHB (1)

The Magneton Numbers of Ferromagnetic Materials. (Ueber die Magnetonenzahlen ferromagnetischer Stoffe.) A. Wolf. *Zeitschrift für Physik,* Vol. 70, July 14, 1931, pages 519-538.

An attempted explanation of the magneton numbers of ferromagnetic elements permits a calculation of the magneton number which agrees well with the observed facts above the Curie point. Ha (1)

Electrical Resistance of Nickel and Iron Wires as Affected by Longitudinal Magnetic Fields. O. Stierstadt. *Physical Review,* Vol. 37, 1931, pages 1356-1366.

The previous work of McKeehan (*Physical Review,* Vol. 36, page 948) and Vilbig (*Archiv für Electrotechnik,* Vol. 22, 1929, page 194) is discussed, and new experiments on the change of resistance of Ni and very pure Fe in longitudinal magnetic fields of low magnitude are described. In the absence of secondary effects, the magnetic field always increases the resistance. The anomalous results of previous workers are due chiefly to incomplete demagnetization of the specimens before each measurement; even the effect of the earth's field may cause errors, and another factor is the presence of soldered joints within the magnetic field. The change of resistance over the whole cycle of magnetization need not show a loop unless the magnetization curve shows hysteresis, and with pure Fe the loop diminishes at high temperatures. The saturation of the change of electrical resistance in magnetic fields occurs at much lower field strengths in ferromagnetic than in normal metals, and it is shown that this can be explained in a general way by the Frank-Sommerfeld theory (*Zeitschrift für Physik,* Vol. 60, 1930, page 682; *Physical Review,* Vol. 43, 1930, page 438; Vol. 44, page 473). WAT (1)

Optical Investigations of Thin Metallic Layers, Particularly of Silver. (Optische Untersuchungen von dünnen Metallschichten, insbesondere bei Silber.) W. Reinders & L. Hamburger. *Recueil Travaux Chimiques Pays-Bas,* Vol. 50, Mar. 15, 1931, pages 351-376.

Previous experiments on the light-absorption powers and ultra-microscopic photography of thin metallic films particularly of Ag deposited in high vacuum were continued. The Ag layers were obtained from Ag wire electrically heated under vacuum of about 10^{-6} mm. Thuringian glass was used as the base material for the deposit. The structure of the films depends on the thickness of the layer, the temperature at which the layer is deposited and the base material. Thicknesses of about 2 atoms of Ag are the limit for layers detectable with the naked eye. An investigation was also made of layers of Cd, W and Hg deposited in a vacuum. The mean grain size was smaller with decreasing mobility of the atoms. Ha (1)

On the Energy Content of Lead near the Supra-Conductivity Break Point. (Über den Energieinhalt des Bleies in der Nähe des Sprungpunktes der Supraleitfähigkeit.) K. Mendelssohn & F. Simon. *Zeitschrift für physikalische Chemie,* Section B, Vol. 16, Feb. 1932, pages 72-76.

An apparatus based on the Linde principle is described which is suited for calorimetric measurements down to 2° abs. with a sensitivity of 0.005°. The equipment was used for plotting heating curves of Pb. Around the break point of supra-conductivity, no abnormal change of the energy content was observed. EF (1)

Certain Photoelectric Properties of Gold. Lloyd W. Morris. *Physical Review,* Vol. 37, 1931, pages 1263-1268.

The photoelectric behavior of a Au filament was studied both during an extended outgassing and later on reaching a stable condition. Full arc sensitivity rose quickly in the initial outgassing period, then decreased slowly to a stable value. Fatigue curves show a systematic change from negative fatigue at the beginning to a gradually increasing positive fatigue which slowly decreased to 0. A shift in long-wave limit consistent with the change in full arc sensitivity was observed. Changes in the photoelectric properties were produced by increasing temperature. Full arc sensitivity decreased slightly. Individual line sensitivity was studied by use of a quartz monochromator. Lines close to the long-wave limit increased enormously in sensitivity with temperature; for those more removed this was less marked; below 2350 A.U. there was a slight decrease. A shift in the long-wave limit toward the red was observed during the outgassing period, and the final fatigueless state. During this latter period curves of photoelectric current per unit light intensity established a shift in long-wave limit from 2560-2610 A.U. between temperatures of 20° and 740° C. WAT (1)

Beryllium, Its Production and Application. Issued by the Zentralstelle für Wissenschaftlich-Technische Forschungsarbeiten des Siemens-Konzerns. Translated by R. Rimbach and A. J. Michel. Chemical Catalog Co., New York, 1932. Cloth, 6¼ × 9¼ inches, 331 pages. Price $10.00.

This is a translation of some two dozen separate articles by a score of authors, which appeared in *Wissenschaftliche Veröffentlichungen a. d. Siemens Konzern,* Vol. 8, No. 1, 1928, reporting the intensive work of the Siemens Company in the preceding five years. An extended correlated abstract of the German publication was given in the August 1929 vol. 1, pages 71, 72, issue of *Metals & Alloys.* It is the main source of information on the preparation of beryllium and its alloys with Cu, Fe and Ni, the bulk of the book relating to the Cu-Be alloys.

The precipitation-hardening phenomena met in these alloys are of great metallurgical interest in relation to the theories involved so that the book might almost as well be entitled "Principles of Precipitation-Hardening." The alloys themselves, by suitable heat-treatment, may be given over 200,000 lbs./in.^{2} tensile strength in wrought material and 125,000 in cast material, remarkable values for a corrosion-resisting non-ferrous alloy.

To make such important information as is contained in this volume available in English by translation, is a distinct service. Whether the interest lies in the scientific facts relating to precipitation hardening, the production and analyses of the alloys, or in the possibilities of commercial application of the alloys described, the book will be of value to the metallurgical engineer, chemist, and executive.

The library of the reviewer's organization paid $9.20 for an unbound copy of the German text, so that the price of the bound English edition is less than that for a bound copy of the German one. H. W. Gillett (1) -B-

Commercial Gallium. *Chemical Trade Journal & Chemical Engineer,* Vol. 90, Mar. 4, 1932, page 242; *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Feb. 7, 1932, page 76.

Quotes *Chemiker-Zeitung* and *Nature* to the effect that the Vereinigte Chemische Fabriken at Leopoldshall, Stassfurt, are producing metallic gallium at 1/20 of its former price of 175 gold marks/gram. The pure metal melts at 20° C. but boils above 2000° C. Some proposed uses are in quartz thermometers for temperatures from 500°-1000° C., in dental amalgams, and in optical mirrors, signalling devices, electric fuses and vapor arc-lamps. JN + GN (1)

Experiments with Silicon (Untersuchungen an Silizium). A. Schulze. *Zeitschrift für technische Physik,* Vol. 11, No. 11, 1930, pages 443-452.

The electric resistance of several kinds of Si up to close to the melting point is determined. Polycrystalline Si shows the normal behavior of semi-conductors; while single crystals are entirely non-metallic, they have a positive temperature coefficient. The latter depends on the layers between the crystallites and their number. The resistance curves up to 1000° C. show clearly that no transformation points exist. A further corroboration is seen in the fact that Si possesses a cubic face-centered lattice both at 18° and at 950° C. Ha (1)

Volatile Thallium and Lead Hydride. (Flüchtiges Thallium und Bleihydrid.) E. Pietsch & F. Seuferling. *Die Naturwissenschaften,* Vol. 19, July 26, 1931, page 574.

TlCl and $PbCl_2$ films were treated with atomic H and the occurrence of the metal hydrides was proved. EF (1)

Chromium. General Information. Lewis A. Smith. *United States Bureau of Mines Information Circular* 6566, Apr. 1932, 31 pages.

A review is given of properties, occurrence, uses, marketing, tariffs, world trade, world production, world resources and political and commercial control. AHE (1)

The Properties of Copper in Relation to Low Stresses. The Effects of Cold-Work, Heat-Treatment, and Composition. Part I.—Tensile and Compression Tests Under Short-Time Loading. O. F. Hudson & J. McKeown. *Institute of Metals, Advance Copy* No. 594, Apr. 1932, 20 pages.

Hot-rolled Cu rods were cold drawn to a reduction of 5 or 10%, and annealed or aged at temperatures between 100° and 400° C. Careful tensile tests proved that such treatment raised the proportional limit of the Cu without appreciably affecting other properties. Coppers containing As, Ag, As plus Ag, and Sn plus Si were also tested. The addition of these elements increased the proportional limit, and in material containing As plus Ag or Sn plus Si the proportional limit was not lowered by heating to 300 or 350° C. Tensile and compression tests at 300 and 350° C. proved that these materials were more resistant to deformation at these temperatures than pure Cu. Cu containing 0.3-0.5% As and 0.1% Ag had a proportional limit of 6.6 tons/in.^{2} after having been held at 200° C. for 100 hr. It is concluded that "the marked superiority of the properties which have been shown to be readily achieved by pre-treatment should warrant the attention of engineers and other users of Cu where resistance to deformation under low stresses is of importance, as it is in so many applications." 6 references. Electrical Conductivity and Optical Absorption in Metals, once more. Edwin H. Hall. *Proceedings, National Academy of Science,* Vol. 17, June 1931, pages 392-401.

Drude's equation of motion of an electron within a metal is discussed with particular reference to "free" and "associated" electrons. The conduction electrons mentioned by Meier may reasonably be taken to be associated electrons. J. J. Thomson's formula $(k \sin^2 nT)/n^2T^2$ applied to transit conductivity gives the same results as those obtained by the author in a different way. The work of Meier and of Hager and Rubens on absorption conductivity is reviewed and discussed. 6 references. Ha (1)

Materials and Load. (Werkstoff und Anstrengung.) Franz Laszlo. *Stahl und Eisen,* Vol. 52, Feb. 25, 1932, pages 189-192.

Theoretical discussion of notch sensitivity with respect to form of materials. The method for calculating measurement theory against change in form is described and research work necessary to obtain these results is given. DTR (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

The Role of Platinum Metals in Dental Alloys. E. M. Wise, Walter S. Crowell & J. T. Eash (International Nickel Co. and S. S. White Dental Mfg. Co.). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 44 pages.

38 references. The binary alloys Ag-Cu, Au-Ag, Au-Cu, Pd-Au, Pd-Ag, Pd-Cu, Pt-Au, Pt-Ag, Pt-Cu, and the ternary systems Au-Ag-Cu and Pd-Ag-Cu are discussed. The diagrams are given, and the properties of the alloys, including their mechanical properties, color, tarnish resistance and ease of melting and working are described. Particular attention is called to the age-hardening properties of some of these alloys. In the second part of the paper the properties of some Pt- and Pd- containing alloys suitable for dental applications are discussed. Results of tests on some of these alloys are also included. Some of these alloys possess a broad age-hardening range. Considerable saving can result by using Pt or Pd in some Au-base dental alloys. JLG (2)

Progress Report on Research on Dental Material (1931). N. O. Taylor & G. C. Paffenbarger. *Journal American Dental Association,* Vol. 19, Mar. 1932, pages 404-409.

A progress report of the coöperative research inaugurated in 1928 by the National Bureau of Standards and the Research Commission of the American Dental Association. The work during 1930-1931 has included studies of amalgams for dental use, inlay golds, and wrought golds. A list of 33 publications giving data on dental research conducted at the National Bureau of Standards is quoted from Bureau of Standards Letter Circular 239. Specifications for the following dental materials have been prepared: (1) Amalgam alloys; (2) inlay casting investments; (3) impression compounds; (4) inlay wax; (5) three types of inlay casting golds; and (6) dental mercury which is included in this report. A plan has been inaugurated, whereby manufacturers of dental material may have their products certified. A list of 28 amalgam alloys from 19 manufacturers, 5 inlay casting investments, 4 impression compounds, and 2 inlay waxes which have been certified is given. The future research program includes wrought golds, clasp and one-piece casting golds, and dental cements. OEH (2)

Alloys of Pd with Pt and with Rh (Ueber die Legierungen des Palladiums mit Platin und mit Rhodium). G. Tammann & H. J. Rocha. *Siebert Festschrift,* 1931, pages 309-320.

Sketchy data on hardness of the Pt-Pd alloys when quenched and after reheating, together with some comments on structure and on the absorption of cathodic hydrogen. The hardness was maximum at 50 atomic % and at that composition was not affected by the heat treatment. With less than 50 atomic % Pd the alloys quenched from 1400° and 1200° C. were harder than those reheated to 600°, and those quenched from 1400° C. were notably harder than those quenched from 1200° C. The hardness of Pt-Rh alloys after a 1200° C. anneal is given, showing a maximum at 50 atomic %. HWG (2)

Tin Base Bearing Metals. (Zinnlagermetalle.) Thews. *Die Metallbörse,* Vol. 21, Nov. 7, 1931, pages 1961-1962; Nov. 14, 1931, pages 1993-1994; Nov. 21, 1931, page 2026.

Requirements to be met with by bearing metals. 12 advantages of bearing metals on Sn base as compared with bearing metals rich in Pb. Two tables of the A.S.T.M. collecting various physical properties of Sn and Pb alloys at room and elevated temperatures respectively are included, and the effect of Cu, Ni, Fe and Zn is considered. Four sources of trouble responsible for the failure of bearing metals are stated in conclusion. EF (2)

A Study of Wrought Gold Alloys: Preliminary Report. N. O. Taylor, G. C. Paffenbarger & W. T. Sweeney. *Journal American Dental Association,* Vol. 19, Mar. 1932, pages 410-414; Discussion pages 414-415.

This report relates largely to test methods which are to be used in research. The alloys which were used in the preliminary work had the following compositions:

Alloy	A	B	C
Gold	63.2	57.6	54.6
Copper	11.3	11.7	12.3
Pt metals	10.6	26.5	24.5
Silver	14.9	4.3	7.1

The alloys were softened by heating 10 minutes at 700° C. and quenching. They were then hardened by reheating to 450° C. and cooling to 250° C. in 30 minutes. Specimens 0.04 in. in diameter and having a 2 in. gage length have been adopted. The deformation is read by a double dial extensometer reading to 0.0001 in. Hardening increased the strength of all of the alloys and was most pronounced in alloy C. The results of tensile tests are given. OEH (2)

The Alloys of Silver and Copper (Sur les alliages argent-cuivre). W. Broniewski & S. Koslacz. *Comptes Rendus,* Vol. 194, Mar. 14, 1932, pages 973-975.

The authors have investigated the relationship between the constitution of this system and 15 different physical constants and have represented the results of their work upon a series of curves which accompany their paper. They find the eutectic of the system to contain 71% Ag and to freeze at 779° C. The maximum solid solubility of Cu in Ag they find to be 7%; that of Ag in Cu, 6%. These solubilities are somewhat less than those noted by Stockdale in his 1931 work. Physical and mechanical properties were studied on alloys cast in graphite crucibles in a cryptol furnace and fabricated into wires 5 mm. in diameter. These were annealed for 12 hours at 650° C. in CO_2. The measures adopted in measuring the various properties have been described by the authors on previous occasions. The authors discuss their work in the light of the work of other investigators. The fact that some precipitation hardening can occur in solid solutions containing less than the maximum percentages of solute metal is referred to. Mention is also made of the fact that the alloys, when prepared in a reducing temperature, are malleable and very ductile, whereas those prepared in oxidizing temperatures (such as cause the formation of cuprous oxide) are markedly affected by the presence of this material. Magnesium and Its Alloys. (Il magnesio e le sue leghe). G. Guzzoni. *Alluminio*, Vol. 1, Jan.-Feb. 1932, pages 50-51.
Condensed from Rendic. 13ª Riun. Assoc. Ital. studi mat. costruzione, Rome, 1931. Summary of tensile properties of chill cast, sand cast and wrought Mg alloys with up to 12% Al, with some comments on Mg Zn and Mg Cu alloys. HWG (2)

Nickel and Its Non-Ferrous Alloys, with Special Reference to Welding. J. McNeil. *Welding Journal*, Vol. 29, Mar. 1932, pages 70-76; discussion, Apr. 1932, pages 106-108.
Paper read before the Institution of Welding Engineers, Jan. 1932. Deals with the physical and chemical properties of Ni and some of its representative non-ferrous alloys, methods of welding Ni and these alloys and some typical applications where welded construction has been employed. Includes general details of oxy-acetylene and metallic arc welding, such as proper flame adjustment and manipulation of the oxy-acetylene torch, composition and use of welding flux and use of coated electrodes. Physical properties of welded joints are given. TEJ (2)

Different Applications of Aluminum Bronze with a Particular Reference to Its Wear Resistance. (Applications diverses du bronze d'aluminium et notes particulières sur sa resistance a l'usure). G. H. Meigh. *Revue de Métallurgie*, Vol. 29, Apr. 1932, pages 208-214.
Al bronze is being substituted for bronze and brass in the French navy. Considerable difficulties due to segregation can be prevented by proper design of the molds and care in metallurgical treatment. Excellent physical properties and resistance to wear can be obtained. JDG (2)

Cast Alloy A. P. 33. (Alliage de Fonderie A. P. 33.) J. Suhr. *Revue de l'Aluminium*, Vol. 9, Mar.-Apr. 1932, pages 1669-1680.
This alloy is an Al with the addition of 4.5% Cu, 0.45% Ti and a minimum of Fe and Si. After heat treatment the mechanical properties are: elastic limit 22-25 kg./mm.^{2}, ultimate strength 30-35 kg./mm.^{2}, elongation 5-8%. The addition of Ti refines the grain but only up to 0.4%. Fe in small proportions does not influence strength and hardness greatly but it should not exceed 0.4% as it has a harmful influence on the properties named. The metallographic study is described in detail. Ha (2)

Silver Alloys. (Etude sur les alliages d'argent.) Leon Guillet, Alfred Petit & Jean Cournot. *Revue de Metallurgie*, Vol. 29, Mar. 1932, pages 113-132; Apr. 1932, pages 183-207.
Contemporary coinage Ag alloys besides requiring a high Ag content have a tendency to tarnish easily and sometimes involve mechanical difficulties in the manufacture. The purpose of the investigation was the development of an alloy which would be satisfactory from the following standpoints: rolling and stamping properties, color, density, stability in contact with substances to which coins are subjected in use, wear resistance and possibility of Ag recovery from the alloy. The survey of equilibrium diagrams and the published data indicated the possibilities for 8 groups of alloys: Ag-Zn, Ag-Cd, Ag-Sn, Ag-Zn-Cu, Ag-Cu-Ni, Ag-Cu-Zn-Cd and Ag-Cu-Ni-Zn. Alloys of Ag with Zn and Cd seem to be quite promising. The advantages of Zn over Cd are: whiter color with larger additions, somewhat better corrosion resistance, homogeneity of ingots, and ease of preparation. Cd makes the metal more malleable. Ag-Zn alloys can be rolled with 20% Zn but with higher amounts break in the rolls. Cd content can be raised to 40% without interfering with rolling. The microscopic study of Ag-Cd system strongly disagrees with the equilibrium diagram proposed by Guertler. Ag-Sn alloys can be made quite uniform, but the brittleness in rolling prevents their use. Cd and Zn are interchangable in the alloys so that with 10% each the alloys can be rolled but with 20% break between the rolls. A series of alloys containing 80, 60, 40% Ag, 10, 20, 45% Cu and 10, 20, 15% Ni showed that the alloys are not miscible and show pronounced segregation. Using 50% Ag, 30-25% Cu, 10-15% Zn and 10% Cd quite good physical results could be obtained but the alloy was not sufficiently corrosion resistant. Ag-Cu-Ni-Zn alloys can be made satisfactory both from mechanical and corrosion resistance standpoints provided that for 40-50% Ag at least 8-12% Ni is available together with at least 30% Cu which however must not exceed 40%. Sufficient Zn is added to make 100%. With higher Ag contents better properties will be obtained in Ag-Cu-Ni-Zn alloys having the following composition: 50-30-10-10, 68-18-6-8, 75-13-5-7. An alloy containing 39% Ag, 36% Cu, 12% Ni and 13% Zn though having a wide solidification range requiring proper means for prevention of segregations is equal or better in physical properties and corrosion resistance than the usual monetary alloy 835 Ag-165 Cu. A comprehensive study of the former is given. Best whitening is obtained with it using a 10% solution of H_2SO_4 to which either 2.5 or 5% $K_2Cr_2O_7$ is added. 10 minutes boiling is sufficient in the former and 5 in the latter. A comparison between 68% Ag-32% Cu alloy and a quarternary alloy 68% Ag-18% Cu-6% Ni-8% Zn basing on physical, metallographic and corrosion resistance study showed that the latter has a much better color and better resistance to corrosion together with the improved physical properties. Many pickling baths were studied for it. Oxidizing heating followed by HNO_3 pickling, another oxidizing heating after which H_2SO_4 pickle is used seem to be the best. The paper has 28 figures and 25 tables. JDG (2)

Lead-Nickel-Cadmium Alloys capable of being Hardened. (Aushärtbare Blei-Nickel-Cadmiumlegierungen.) B. Garre & A. Mueller. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 205, Apr. 8, 1932, page 42.
By adding up to 6% $NiCd_4$ to Pb the alloy can be hardened after annealing for a certain time. The results are shown in diagrams. Pure Pb will withstand strong H_2SO_4 better, but the alloyed Pb will behave better with dilute 10% H_2SO_4. Ha (2)

Production and Use of Light Metals and Their Alloys in Italy. (Production et application des metaux legers et de leurs alliages en Italie.) A. W. Bonaretti. *Revue de Metallurgie*, Vol. 28, May 1931, page 269.

The Change of Electrical Resistance and Hardness of a few Alloys of Lead and Thallium with Time. (Die zeitliche Aenderung des elektrischen Widerstands und der Härte von einigen Legierungen des Bleis und des Thalliums.) G. Tammann & H. Ruediger. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 192, Sept. 1930, pages 1-44.
A number of binary alloys of Pb with Cd, Bi, Sn, Na, K and Hg, and of Th with Pb, Hg and Sn were investigated with respect to the change by aging of the electric resistance and hardness. The results are given in numerous curves and numerical tables and show these properties as a function of composition, heat treatment and time. The behavior is explained by phenomena occurring in the saturated or unsaturated solid solutions according to heat treatment and composition. Ha (2)

The Effects of Cold-Rolling and of Heat-Treatment on Some Lead Alloys. H. Waterhouse & R. Willows. *Engineering*, Vol. 132, Sept. 18, 1932, pages 381-382, 387-388.
Includes discussion. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 2. LFM (2)

Corrosion-Resisting Aluminum Alloy. (Korrosionsbeständige Aluminiumlegierung.) E. Wolf. *Chemische Fabrik*, Vol. 4, Dec. 1931, page 453; *Autogene Metallbearbeitung*, Vol. 25, May 15, 1932, pages 157-158.
A new Al alloy "AW 15" of the Aluminum Works Singen is described which consists of 98% Al and 2% Mn; impurities of Fe and Si are of the same order as in pure Al. The tensile strength exceeds that of Al; it is very well suited to deep-drawing, spinning, stamping, etc. It can be soldered and welded without special fluxes. It has a great corrosion resistance and can be used for kitchen ware and in the chemical industry. Ha (2)

Rolled Rods of Aluminum. (Walzstäbe aus Aluminium.) *Aluminium*, Vol. 14, Jan. 31, 1932, pages 3-4.
Discussion of alleged American practice. Ha (2)

Aluminum and Its Alloys. L. W. Kempf. *Conference on Metals and Alloys, Case School of Applied Science*, Cleveland, Ohio, Nov. 1931, paper No. 10, 7 pages. Mimeographed.
General discussion, with special attention to heat-treatment of cast and wrought alloys. The use of Mg as alloying element in a binary Al-Mg alloy has so far met with little success but the difficulties of difficult workability in wrought alloys and of reaction with green sand in cast alloys are being overcome, so that wider use is expected. HWG (2)

Hardenable Gold Alloys. (Härtbare Goldlegierungen). *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Apr. 24, 1932, page 228.
The application of hardenable Au alloys to spinning dies for the fabrication of artificial silk products is briefly mentioned. Whereas there were previously used for this purpose dies of pure Pt and alloys of Pt and Ir, there were later applied cheaper alloys of either 90% Au/10% Pt and 90% Au/10% Ir. These and similar alloys can furthermore be improved by age-hardening and then are much more resistive against mechanical strain. They are superior to other material. GN (2)

Super-Conductivity of Gold-Bismuth. (Die Supraleitfähigkeit des Gold-Wismuts.) W. J. de Haas & F. Jurriaanse. *Die Naturwissenschaften*, Vol. 19, Aug. 14, 1931, page 706.
Au-Bi alloys became supra-conductant, although the single metals do not display this property. The binary diagram of Vogel was corrected. Solution tests on the eutectic yielded crystals of Au_2Bi, which is responsible for the supra-conductivity phenomenon. The space lattice of this intermetallic compound is supposed to be tetragonal, at least different from that of Au and Bi respectively. EF (2)

The Thermal Conductivity of Some Non-Ferrous Alloys. D. Hanson & C. E. Rodgers. *Institute of Metals, Advance Copy* No. 593, Apr. 1932, 6 pages.
Thermal conductivity measurements were made by the "guard-tube" method. Results are given for a series of Cu-Al alloys, both Cu-rich and Al-rich. The effects of small amounts of Fe, Ni, As and P on the thermal conductivity of Cu are also shown. JLG (2)

Non-Ferrous Metals. I. Light Metals. (Nichteisenmetalle. I. Leichtmetalle.) H. Christen. *Schweizerische Technische Zeitschrift*, Vol. 29, Mar. 17, 1932, pages 153-159.
The article gives a detailed survey of composition and properties of light metal alloys with special reference to those of the Al-Mg type. These metals are considered in 2 groups, cast alloys and malleable alloys. Among the first group there are dealt with (1) Alufont, produced by the Aluminium Industrie A.G., Neuhausen, Switzerland, (2), the American alloy No. 12, (3) Silumin, (4) K.S. Seawater, (5) Anticorodal, an alloy made by the Aluminium Industrie A.G., with a particularly high resistance to corrosion. Among the malleable alloys discussed are: (1) Duralumin, (2) Avional, made by the A.I.A.G., the composition of which corresponds about to that of Duralumin, (3) Anticorodal, (4) Aldrey which is successfully used for transmission of electric current, (5) Electron with about 90% Mg contains Zn, Mn, Al, Si, Cu and Cd. The paper is supplemented by a review of the literature and contains 7 references. GN (2)

The Compressive Strength of Duralumin Columns of Equal Angle Section. E. E. Lundquist. *Technical Notes, National Advisory Committee for Aeronautics*, No. 413, Mar. 1932, 12 pages. Mimeographed.
Duralumin angles of equal leg widths, in different widths (1¼" to ½") and thicknesses (0.4" to 0.125") and in different lengths were tested in compression, noting whether failure was by twisting, bending, wrinkling, etc. The data are collected into column charts showing stress for failure vs. different 1/r ratios, for coefficients of end fixity equalling 1 and 2. PROPERTIES OF FERROUS ALLOYS (3)

Effect of Machining on Transverse Test Results of Cast Iron. (Einfluss der Bearbeitung auf die Ergebnisse des Biegeversuchs bei Gusseisen.) GUSTAV MEYERSBERG. *Archiv für das Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 511-512.

Deflection, modulus of rupture, and strain number were determined on 592 test rods of various brands of cast Fe. For the transverse tests, bars 650 mm. long, width between supports 600 mm., were divided into 3 groups: Group I—ordinary rough rods, 30 mm. diam.; Group II—half machined rods, cast 34 mm. diam. and machined to 30 mm. diam. over 200 mm. length equidistant from ends of rods. Group III—completely machined rods; cast 34 mm. diam. and turned to 30 mm. diam. over entire length of rod. Comparison of average values shows that a slight increase of deflection (f) and modulus of rupture (σ_B) for Group II rods as against Group I. The strain number (Z_f) remains practically constant. Group III rods show further increases only for (f) and Z_f scarcely any increase for σ_B. The deviations in test results, computed graphically, showed somewhat less values for completely turned rods than for rough cast samples, an indication that the release of casting stresses is the characteristic difference which chiefly distinguishes machined rods from unworked material.

Cast Iron Brand	f-Deflection mm.			Modulus of Rupture σ_B Kg./mm.^{2}			Strain Number, Z_f $\frac{mm.^3}{Kg.} \times 100$

Physical Properties of Steel After Plastic and Yield-Point Extension. J. MUIR. *Journal Royal Technical College* (Glasgow), Vol. 2, Jan. 1932, pages 571-586.

The great difference between the elastic properties of steel stretched by successive yield-points or by single loading to the same amount is dealt with. By "yield-points" the author apparently refers to a definite elongation (2%). Experiments on wires and rods are described, and a brief review of the single crystal experiments of Joffé and of the elastic hysteresis theory of Prandtl is given. Yield-point extension is likened to a shift such as twinning in a single crystal, and plastic extension to gliding. The outstanding differences in elastic properties suggested a search for other manifestations of change of state, and experimental work undertaken at different times on slip-bands, density, electric resistance, magnetic and thermoelectric properties are brought together and briefly described. It is shown that whereas steel stretched (1) by yield-points (2) to the same extent by a single loading, possesses very different elastic properties, it does not appear to differ appreciably in any other property. Austenitic Cast Iron. J. E. HURST. *Machinery, London,* Vol. 39, Feb. 4, 1932, pages 586-587.

See *Metals & Alloys,* Vol. 3, July 1932, page MA 197. (3)

Aging Notch Toughness and Force Influence Figure Etching. (Alterungskerbzähigkeit und Kraftwirkungsfiguren-Aetzung). F. NEHL. *Archiv für Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 535-536.

Includes discussion. After review of literature on aging of boiler tubes, the author found that notch strength after aging for Izett steel tubes and ordinary open hearth steel tubes were alike. A special notch impact test-piece was designed for examining boiler tubes, in addition to the usual test size of 15 × 30 × 160 mm., with impact cross-section 15 × 15 mm. In normalized condition the test pieces showed an average notch strength of 18.3 mkg./cm.^{2}, while in artificially aged state 2.5 mkg./cm.^{2}, a pronounced difference. Total of 1,000 hydrogen-welded high safety factor boiler drums produced from 1924 to 1931 showed no defects due to aging or fatigue causes either in drums or in boiler tube systems. In discussion H. Jungbluth started with sheets 20 mm. thick and drawn to 5 or 7 mm.

Material	Thickness	Composition % C	% Si	% Mn	% P	% S
A	5	0.09	0.01	0.47	0.016	0.019
J	7	0.12	0.05	0.46	0.016	0.024

Notch strength—temperature curves in annealed and aged materials are given. Difference between aging resistant and non-resistant material lies in amount of cold roll reduction. DTR(3)

Izett Steel. G. G. NEUENDORFF. *Metals & Alloys,* Vol. 3, Mar. 1932, pages 61 68.

14 references. The author describes the superior toughness of "Izett" steel to common boiler plate. It is not markedly affected by aging after cold work with resultant embrittlement. A large amount of data is given on notched bar tests of both steels. This new German steel seems to owe its properties to special methods of melting and working and to the skill of the metallurgical supervision of these operations. Information is given and applications discussed where Izett is welded and riveted into various types of boiler or pressure containers. WLC (3)

The Wear and Surface Condition of Cast Iron. *Metallurgist,* Sept. 1931, pages 132-134.

Brinell Hardness and Tensile Strength of Cast Iron. J. G. PEARCE. *Bulletin British Cast Iron Research Association,* Vol. 3, Apr. 1932, page 85.

A series of tests was made to find a possible way to express tensile strength in terms of Brinell hardness. The formula: $\text{Tensile Strength} = \frac{\text{Brinell Hardness}}{8} - a$ where a is a constant found in the tests as varying between 11.5 and 17.5, gave however too unreliable results to be of any practical value for the adoption for specifications. No relation was found between hardness and machinability or hardness and abrasive wear. Ha (3)

The Effect of Superheating and Casting Temperature on Common Commercial and Machinery Cast Iron. (Der Einfluss der Ueberhitzung und der Vergiesstemperatur auf gewöhnlichen Handels- und Maschinenguss.) H. PINSL. *Zeitschrift für gesamte Giessereipraxis,* Vol. 53, Apr. 17, 1932, pages 153-156.

The paper first refers to the German investigations on the effect of superheating on the properties of cast iron and then deals with the experiences of a German cast iron foundry in superheating. The results of superheating on the mechanical properties of cast iron to be used for tubes and made in a reverberatory furnace as well as the effect of the casting temperature on hardness and impact hardness of cast iron to be used for brakes are shown in diagrams. GN (3)

The Curie Point in Ferro-Cerium (Point de Curie du ferro-cérium). G. RASSAT. *Comptes Rendus,* Vol. 194, Apr. 4, 1932, page 1153.

The author has observed that samples of ferro-cerium containing approximately 27.5% Fe lose their magnetism in the neighborhood of 40° C. In the case of ferro-cerium containing 32% Fe, the phenomenon is less distinct. At 40° C. there is a definite diminution in attraction, but magnetism does not disappear completely, persisting up to the temperature of combustion of ferro-cerium. The author suggests that the loss of magnetism of these alloys might be put to use in connection with apparatus for the control of temperature, etc. OWE (33)

The Relation between the Effective Flowing Stress and Hardness. (Ueber die Beziehung zwischen effektiver Fliessspannung und Härte.) F. SAUERWALD & F. RAKOSKI. *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, pages 95-96.

Tensile bars of mild steel were stressed to values between the yield point and the tensile strength, and then removed and their hardness measured ("fall-hardness"). It was found that a simple proportionality existed between degree of stressing and the hardness. RFM (3)

Magnetic and Mechanical Hardness of Dispersion Hardened Iron Alloys. K. S. SELJESATER & B. A. ROGERS. *Transactions American Society for Steel Treating,* Vol. 19, Apr. 1932, pages 553-576.

Includes discussion and 12 references. The authors describe the magnetic and mechanical properties of certain carbonless Fe alloys with W, Mo, Be and Ti. Ternary alloys where the base of the alloy was Fe 65%, Co 35% instead of pure Fe were also studied. Graphs show the change of mechanical hardness with aging temperature as well as the magnetic properties. In discussion the authors suggest a relation between the effective percentage of the precipitating element and the molecular weight of the compound precipitated. Binary alloys of Fe-W are shown to have the properties of good permanent magnets. Fe-Mo alloy exhibits the highest coercive force, Be alloys attain the highest mechanical hardness and Ti alloys exhibit maximum mechanical and magnetic hardness at quite different aging temperatures. In the ternary Fe-Co-W the same feature of minimum coercive force at maximum mechanical hardness as was found in Fe-Ti alloys is displayed and the maximum coercive force is obtained at somewhat higher aging temperature. Where high hardness is obtainable by aging the possibility of these alloys for tools is suggested. WLC (3)

Electric Cast Iron. (Elektro-Gusseisen.) W. HEIMANN. *Maschinenkonstrukteur-Betriebstechnik,* Vol. 64, Aug. 10, 1931, pages 175-176.

The quality of cast Fe should be improved, and the loading capacity increased. Quality can be obtained by electric furnace melting. A typical induction furnace is described. Good melting means good properties, high tensile strength, and good machinability. The composition and temperature of the Fe in the bath should be carefully regulated. A cast Fe with (the usual) 3% C alloyed with Si, Mn, P, and S will have varied properties. It is affected as steel is by Cr, Cu and Ni. The C content can be regulated in the electric furnace to an accuracy of 0.1%. Si (1.5-2.5%) improves the machinability of gray castings by formation of graphite. Si and Mn content may be regulated to an accuracy of 0.1-0.2% in the electrical furnace. The structure of the casting with respect to the graphite is of prime importance. A pearlitic matrix in a 3% C Fe should have 0.9% combined C (carbide) with the remaining C as graphite. If the graphite is below 2%, the Fe becomes hard and brittle. MAB (3)

Industrial Steels and Alloys. J. W. DONALDSON. *Heat Treating & Forging,* Vol. 18, Feb. 1932, pages 107-109; Apr. 1932, pages 242-244.

The Poisoning of Reactions in Heterogenous Systems. (Die Vergiftung der Reaktionen in heterogenen Systemen.) K. Jablczynski & J. Maczkowska. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 197, Apr. 30, 1931, pages 292-300.

Additions of very dilute solutions of H_2S, KCN, and As_2O_3 act as poison to the dissolution of Mg in 0.1 *N* HCl. The dissolving velocity of technical Zn in 0.1 *N* HCl is greatly reduced by KCN; As_2O_3, H_2S and iodine have an activating effect. The latter additions increase the dissolving velocity 77, 30 and 17% respectively. Ha (4)

The Significance of the Hydrogen Absorption of Iron During the Corrosion Process. (Die Bedeutung der Wasserstoffaufnahme des Eisens für den Korrosionsvorgang.) E. Liebreich. *Korrosion und Metallschutz*, Vol. 8, Jan. 1932, pages 1-4.

The hydrogen originated at the surface of iron is (a) partly transferred into water due to the oxygen in solution, (b) partly diffused into the solution if oxygen is absent, and (c) partly occluded at the iron surface and later migrating along the grain boundaries into the interior regions. The last phenomenon, largely dealt with in the paper, is proved according to Förster by the electrochemical potential which, in contrast to Al or Mg, is shifted to negative values. The writer furnished a new proof by studying the cathodic over-voltage of steel wires which were employed in a fresh state and after a 24 hours exposure to the corrosive attack of a KCl solution. The cathodic over-voltage phenomenon, which has not always been duly recognized, is complicated by the uneven absorption and occlusion of hydrogen resulting in the formation of local elements. The accelerated corrosion rate at spots in contact with foreign matter has not been fully explained yet. The interpretation of Evans based on differential aeration is rejected by the writer on account of his fundamental "drop (suspended) test" and "plate test" (partly submerged). In addition to the effect of occluded hydrogen which renders the potential less noble, an acceleration of the corrosion attack is caused by the bi-valent corrosion products. The writer assumes that the "physical depolarization," i. e. the diffusion of hydrogen into the solution is retarded or even completely suppressed by the viscous hydroxide layer formed at the iron surface. Consequently the hydrogen liberated exerts a higher pressure resulting in an increased migration into the interior parts of the metal. This merely mechanical procedure can be proved if the gas is not allowed to escape, accomplished by partly covering the surface of the iron with dustlike glass powder and then exposing the metal to the attack of an electrolyte in a hydrogen atmosphere. Those spots covered by foreign matter are pitted more effectively. The prevention of the mechanical depolarization is responsible for many corrosion attacks in daily life and industry. However, the corrosion due to the differential aeration of a metal surface may principally occur. 14 references. EF (4)

Corrosion as a Physico-Chemical Problem. (Die Korrosion als physikalisch-chemisches Problem.) H. Mark. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde and the Verein deutscher Chemiker*, Oct. 20, 1931, Berlin.

The investigations on catalysis on the one hand and on the corrosion of metals on the other hand indicate that they both have many similar aspects. In both cases, it is a study of occurrences on surfaces which are effected by the area of the surface and its activity. In order to determine these 2 factors independently one of the other, it is necessary to study the dependence of the occurrences upon the temperature. This has repeatedly been done for the catalysis. The present status of catalysis is reviewed and its relations to the problems of corrosion are discussed. GN (4)

From Empirical to Fundamental Facts of Corrosion. (Vom Empirischen zum Grundsätzlichen im Einzelfalle der Korrosion.) G. Masing. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde and the Verein deutscher Chemiker*, Oct. 20, 1931, Berlin.

In the cases of Fe, Cu, Al and Ni, the author shows that it is possible to arrive at definite conclusions as to their corrosion behavior in considering the elementary electro-chemical principles of corrosion. Cu is distinguished by a rather noble potential (+0.34) and, therefore, does not develop H in acids. Cu_2O does not adhere to the metal and does not offer protection. Cu therefore easily oxidizes and is rather insensible towards acids. In comparison with Cu, Al is not noble but owes its technical application to the adherence of its oxide to the metal. The difference in the potential of Fe'' and Fe''' offers various possibilities of increasing the corrosion resistance of Fe. This can be done either by favoring the oxidation and accelerating the formation of Fe''' and thus making Fe passive or by decreasing the solubility of FeO, for instance in alkalic solutions, or by alloying it with metals which form insoluble oxides, as for instance Cr. The potential of Ni (—0.25 Volt) is between that of Cu and Fe. It results that Ni is not stable against the attack of strong acids but practically stable against weak acids. In neutral electrolytes Ni stands up much better than Fe probably because the NiO formed is much less soluble than FeO. GN (4)

Combating Corrosion in the Textile Industry. R. Cottrell. *Textile World*, Vol. 79, May 2, 1931, pages 70-73.

Corrosion difficulties encountered in the textile industry and the damages done by them are discussed. Data pertaining to the action of various chemicals on the materials used for textile equipment are tabulated and suggestions made for the proper selection of appropriate materials for equipment. Advantages in the use of Monel metal and other Ni-bearing alloys are pointed out. Ha (4)

Corrosion of Aluminum Alloys in Superheated Steam. (La Corrosion des Alliages d'Aluminium dans la Vapeur d'eau surchauffee.) Leon Guillett & M. Ballay. *Aciers Speciaux, Metaux et Alliages*, Vol. 6, July 1931, page 361.

Metals That Resist Alkali Corrosion. John L. Everhart. *Chemical & Metallurgical Engineering*, Vol. 39, Feb. 1932, page 88.

General corrosion data are given for 10 metals tested in mixed alkali liquors. Ni and Ni rich alloys resist caustic soda liquors, though cast iron is usable because of low cost. Cast iron and cast steel resist sodium carbonate liquors. Ni-Cr-Mo (35-25-5) alloy is resistant to ammonium chloride liquors. Cast iron and 18-8 resist sodium chloride-ammonium hydroxide mixtures. Monel metal shows excellent resistance to calcium chloride liquor. PRK (4)

Safe-Guarding Cracking Operations from Accident. E. M. Matson. *Refiner & Natural Gasoline Manufacturer*, Vol. 10, May 1931, pages 99-101; June 1931, pages 110, 112.

The paper deals with corrosion of cracking equipment. WHB (4)

The Use of Neutralizers for Inhibiting Corrosion of Refinery Equipment. L. G. Metcalf. (Union Oil Co. of Calif.) *Proceedings American Petroleum Institute*, Dec. 1931, Section IV, pages 110-121.

This is the report of the Sub-Committee on Neutralizers appointed in Nov. 1930 and consists of information derived from a questionnaire to 27 refiners, 17 of whom replied. Corrosion of refinery equipment is broadly classified as (1) low-temperature corrosion in the presence of water and (2) high-temperature corrosion. Low-temperature corrosion in the presence of water is encountered in most distillation equipment in the cooling and condensing systems where the temperature and pressure conditions are such that water can be condensed. The factors influencing such corrosion are the acidity or alkalinity of the corroding water solution, the presence of dissimilar metals, and turbulence. The corrosive agents are (1) HCl formed by the hydrolysis of Mg and calcium chlorides accompanying a wet crude oil, (2) H_2S, (3) CO_2, a negligible factor when compared with HCl and H_2S, (4) dissolved O which is also a negligible factor on the oil side of condensing equipment and (5) organic acids which are important in California crudes where the acid number may be as high as 2 or 3 but not with Eastern or Mid-Continent crudes. The neutralizers in use for low-temperature corrosion are (1) ammonia, which is used either in liquid or vapor form, (2) caustic soda, which is used especially for neutralizing H_2S for which purpose ammonia cannot be used, and (3) soda ash which has no advantage over the other neutralizers save that of lessened cost. The most important factors influencing high-temperature corrosion are temperature and turbulence. The corrosive agents in this type of corrosion are free sulphur and sulphur compounds, naphthenic acids and inorganic acids such as HCl and sulphurous acid when accompanied by water or an aqueous film. The neutralizers used for high-temperature corrosion are lime, caustic soda and ammonia. The detailed experience of the various refiners in the use of neutralizers is given. The question of cost is also considered with the conclusion that for inhibiting low-temperature corrosion, neutralizers may show a real saving but for inhibiting high-temperature corrosion careful attention is necessary to insure against excessive costs and inadequate returns. VVK (4)

Opening Remarks to the Group Session on Corrosion of Oil Field Equipment. C. R. Weidner. (Prairie Pipe Line Co.) *Proceedings American Petroleum Institute*, Dec. 1931, Section IV, page 26.

Introduction to the Group Session on Corrosion of Oil Field Equipment by the Chairman of the Committee on Corrosion of Oil Field Equipment. Progress in combating corrosion in the oil industry has consisted in (1) the preparation and distribution of a code of good practice in the application of protective coatings, (2) the recognition of corrosion mitigation as an economic problem, (3) the identification of inadequate and uneconomic coatings on existing pipe lines, (4) the determination of some of the causes of coating failures such as soil stress and mechanical distortion, (5) progress in determining the corrosivity of soils, (6) the stimulation of interest in the corrosion problem by the publicity given to it by the committee. It is estimated that over a million dollars has been saved in the oil industry in the past few years by the work of the Committee and the Bureau of Standards. VVK (4)

Treat Refinery Gases to Reduce Corrosion of Gasoline Recovery Plant Equipment. W. T. Ziegenhain. *Oil & Gas Journal*, Vol. 30, Feb. 4, 1932, pages 10-11.

To minimize corrosion in the vapor recovery system at the Gulf Refining Co.'s plant at Port Arthur, Texas, two Koppers treating plants for the removal of H_2S from the gas have been installed. 9,000,000 ft.^{3} of gas per day from crude stills, coking stills and various pressure cracking units handling high S oils is treated, the H_2S removal ranging from 88 to 98%. This process is the Seaboard liquid purification process and was described in detail by D. J. Jacobson in the *Oil & Gas Journal*, Apr. 4, 1929, page 116. VVK (4)

Operating a High-Pressure Boiler Plant. (Aus dem Betrieb eines Hockdruckdampf-Kesselhauses.) *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Dec. 1931, pages 357-358.

Discusses the difficulties encountered by flaking (rust) and scaling in the operation of a boiler plant. The different detrimental effects of coal dust and ashes are considered as well as that of H_2SO_4 which is present in the waste gases. Ways of removing the acid are given. MAB (4)

Corrosion From Flue Gases. *World Power*, Vol. 27, Feb. 1932, page 122.

Every industrial fuel contains some S and H, with the result that S and moisture inevitably occur in flue gases. When gases are reduced to the dew point of the vapor, combination of the S (whether existing as SO_2 or SO_3) will occur, forming an acid solution which acts corrosively. Such corrosion frequently occurs at economiser headers, in air heaters and the surfaces of steel flues, even when the exit gas temperatures are well above the dew point. To avoid such corrosion, therefore, it is necessary to heat the feed-water to at least 100° F., preferably 120° F., with cast Fe economisers, and with steel 130°-140° F. The increased temperature of the feedwater, naturally, involves some decrease in the efficiency of the heat exchange. This, however, is less serious than occurrence of corrosion. (4)

The Action of Alkalies and Salts upon Mild Steel under High Pressure Conditions and the Protective Action of Sodium Sulphate Against Attack. (Ueber die Einwirkung von Laugen und Salzen auf Flusseisen unter Hockdruckbedingungen und über die Schutzwirkung von Natriumsulfat gegen den Angriff von Aetznatron und von Chlormagnesium.) E. Berl & F. van Taack. No. 330 of the series "Forschungsarbeiten auf dem Gebiete des Ingenieurwesens" published by VDI-Verlag G.m.b.H. 1930, 32 pages, 34 figures & 33 tables, price 5 RM.

This contribution continues the earlier research work carried out by the Feed Water Committee of the Verein Deutscher Ingenieure upon the corrosion of steam boilers. The intercrystalline attack of caustic soda on boiler metal at riveted seams had been recognized. In this research, corrosion tests have been extended to include a very great number of salts. Mild steel was enclosed in a bomb capable of withstanding a pressure of more than 250 atmospheres and exposed to the same conditions as in the actual operation of high-pressure steam boilers. It was found that sodium sulphate not only prevents embrittlement but also prevents purely chemical corrosion up to a concentration of 50 g./l. of caustic soda. Nitrates and phosphates exert a similar action while chromates have the effect of increasing the attack when in alkaline solution. Sodium sulphate also represses the action of magnesium chloride or HCl at high temperature. The explanation of the protective action is to be found in the fact that sodium sulphate promotes the formation of a protective layer of oxide on the Fe. The nature of the oxide is investigated by X-ray analysis. Coatings of Ni and Cr were investigated, both proving effective against caustic soda. However the Ni layer was dissolved by magnesium chloride which, on the other hand did not affect the Cr layer provided it was sufficiently thick. A wealth of data is given on the effect of various salt solutions on iron. VVK (4)

Occurrences of Corrosion in High-Pressure Steam Boilers. (Korrosionserscheinungen in Hochleistungsdampfkesseln.) F. Lupberger. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde and the Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

The paper gives a survey on the occurrences of corrosion in high-pressure steam boilers: corrosion through chemically pure water or through salts dissolved in it, corrosion through the chemical reaction between iron and either water or steam, and corrosion through waste gases. The remedies are discussed. GN (4)

Caustic Embrittlement of Steel. (Über die "Laugenbrüchigkeit" des Stahles.) F. Hundeshagen. *Chemiker-Zeitung,* Vol. 56, Jan. 2, 1932, pages 4-5; Jan. 6, 1932, pages 17-18; Jan. 13, 1932, pages 39-40.

The literature on caustic embrittlement is reviewed and 33 references are given. Embrittlement of steel in boilers occurs at points of highest stress, around bolt and rivet holes, along seams and on rivets. It occurs oftener in high pressure boilers. At these points the tensile, transverse and especially the impact strength is reduced. Microscopic examination shows intercrystalline cracks without plastic flow. According to the *American* theory embrittlement is caused mainly by NaOH which is formed in the boiler from Na_2CO_3 present in the water or added as softening treatment. At the water line, at seams and in crevices NaOH reaches higher concentrations due to evaporation of water and attacks the intercrystalline cement and the impurities in the steel which segregate at the grain boundaries. Conditions considered necessary for caustic embrittlement to take place are high mechanical stress in the steel, above the yield point, the NaOH concentration of at least 300 g./l. NaOH is considered the only chemical which causes embrittlement. Sulphates in sufficient quantity act as a preventive and sulphates are purposely added to boiler water as a protection. In contrast to this the *German* theory claims that embrittlement is not due to caustic alkali, that it takes place at times in the complete absence of NaOH, and that fractures sometimes occur above the water line. Instead it is due to over-straining and overheating of the steel and to improper design and operation of the boilers. Sulphates do not prevent embrittlement. Nitrates and Ca $(OH)_2$ aid, $CaCl_2$ and Na_2CO_3 retard embrittlement. To prevent embrittlement a good quality of steel should be used and the boilers should be properly constructed and operated under correct working conditions. Chromates added to the water break down at higher temperatures but phosphates are beneficial. CEM (4)

Caustic Embrittlement in Boilers. H. E. Wallsom. *Fuel Economist,* Vol. 7, Feb. 1932, pages 163-166.

A number of good points are brought out. (1) Steel in contact with caustic soda in solution suffers corrosion by embrittlement. (2) For such embrittlement to occur, it is essential that the steel should previously have been stressed —a condition which is very usual in boiler construction. (3) Caustic embrittlement may be prevented or inhibited by a maintenance in the water in contact with the steel, of a definite concentration of Na_2SO_4 in relation to concentration of NaOH. This ratio varies with pressure and temperature at which the action takes place. It is preferable that other compounds, such as Na_3PO_4, should be used together with Na_2SO_4, to act, in addition to inhibitors, as precipitating reagents for harmful compounds likely to be formed by introduction of Na_2SO_4. The Anodic Treatment of Aluminium. Edwin Joyce. *Brass World,* Vol. 28, Feb. 1932, pages 29-32.

A protective oxide coating is formed by electrolysis. The Al or Al-alloy is connected to the positive terminal of the generator and electrolysis is conducted in a 3-10% Cr_2O_3 solution. Oxygen liberated at the cathode produces the oxide coating. The process is detailed and the nature of the coating and the cost of operation discussed. Discussion brought out that the presence of a small amount of CrO_3 in the coating is advantageous, while with the H_2SO_4 process retained acid counteracts the corrosion resisting properties of the oxide-coated Al. Protection of Light Alloys Against Corrosion. (La Protection des Alliages Légers Contre la Corrosion.) M. Pubellier. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Nov. 1931, pages 575-585.

The most important part of this article, which is only a review of the subject as is found in literature, is the aging tests made by a Swiss company on soft metals. These tests revealed the fact that in natural aging the difference of electrical potential remained always positive whereas in artificial aging at 150° C. this potential dropped to the negative side after 6 hours and continued to decrease with the duration of aging at 150° C. Protection of Aluminum by Anodic Treatment. Joseph Rossman. *Metal Industry,* N. Y., Vol. 30, Feb. 1932, pages 51-52; Mar. 1932, pages 108-110.

Methods, as disclosed in the patent literature, are described for anodically treating Al. PRK (4)

Corrosion of Duralumin Rivets. J. E. Sullivan. *Aviation,* Vol. 30, June 1931, pages 347-349.

The frequently experienced severe corrosion of duralumin rivets in sea water can be traced to wrong heat treatment of the rivets. It is recommended that the rivets should be heated for at least 20 min. to 510° C., quenched in plenty of cold water and used within 30 minutes. Storing the rivets at 0° C. prevents hardening so that they keep in good condition for use for 24 hours. Ha (4)

The Behavior of Aluminum and Aluminum Alloys in Hydrogen Peroxide Solutions. (Das Verhalten von Aluminium und Aluminiumlegierungen in Wasserstoffsuperoxydlösungen.) W. Wiederholt. *Korrosion und Metallschutz,* Vol. 8, Jan. 1932, pages 4-15.

14 references. Presents the results of tests on a large scale on 3 grades of pure Al containing 98/99%, 99% and 99.5% Al and on 8 different Al alloys containing various amounts of Zn, Cu, Mn, Si, Mg, Sb and alkalies. The samples were tested in H_2O_2 solutions of the following concentrations: 60, 50, 45, 40, 30, 15, 9, 5, 0.9, 0.5 and 0.05% by weight. Some sets of experiments were carried out in the absence of day light. The results may be summarized as follows: Low additions of H_2O_2 (up to about 1%) intensify the formation of a protective film on pure Al recognized by a more pronounced discoloration. H_2O_2 is decomposed by Al. Oxygen bubbles occur which stick tightly to the surface of the metal. Underneath these spots no protective layer is formed but corrosion takes place accompanied by the precipitation of Al hydroxide. The extent of the corrosion attack depends directly on the number of the occurring gas bubbles which however appear quite irregular. Higher H_2O_2 concentrations increase the acidity of the solution, the corrosion products being precipitated in a soluble form. A general attack of the entire surface can be noticed. The corrosion rate, however, is very low. The largest corrosion speed observed amounted to 200 years for a 1 mm. sheet. Besides its concentration, the amount of liquid per 1 cm^2 metallic surface proved to be of importance. Using 1 cc. solution (5 and 9% H_2O_2) on 1 cm^2 surface, the solution product of $Al(OH)_3$ is exceeded, a flocculent precipitate occurs and the enrichment of the corrosion products led to local disturbances of the corrosion attack. The acidulous character of the solutions shows up to 30% H_2O_2. Between 40 and 60%, the oxidizing effect of the reagent predominates and the corrosion products are immediately oxidized and deposited in a tightly adherent form somewhat similar to the anodic oxidation phenomenon. The different behavior of Al submitted to the attack of H_2O_2 solutions of various concentrations is due to the different kinds of deposition and formation. The effect of H_2O_2 solutions exerted on the various Al alloys is analogous to pure Al in regard to the kind and magnitude of the corrosion attack. Sodium silicate additions cut down the attack in solutions of low concentrations. The protective layers formed by H_2O_2 solutions withstood favorably the attack of a 10% HCl and *N* NaOH solution. Resistance of Iron-aluminum Alloys to Oxidation at High Temperatures. N. A. Ziegler (Westinghouse Electric & Mfg. Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 450, Feb. 1932, 6 pages.

Vacuum melted alloys containing as much as 7.95 Al and from practically nil to 0.4% C were used. Small discs of the forged materials were heated for 2 hr. intervals from 600 to 1100° C. (at 100° intervals) in an oxidizing atmosphere. The samples were weighed before heat treatment, the scale ground off after treatment, and the oxidation estimated from the change in weight. Even 2% Al greatly increased the resistance to oxidation. The highest Al alloys were the most resistant, but the 6% Al alloys were almost as good. The 6% Al alloys were only slightly inferior to an 80-20 Ni-Cr alloy. The C content had little effect on the oxidation. JLG (4)

Reduction Potential of Quadrivalent to Trivalent Iridium in Hydrochloric Acid Solutions. Sho-Chow Woo. *Journal American Chemical Society,* Vol. 53, Feb. 1931, pages 469-472.

Results of electromotive force measurements and the free energy decrease and heat content decrease of the reduction of quadrivalent to trivalent iridium ion are given. MEH(4)

Copper in the Manufacture of Condenser Tubes of Steam Turbines. (Le Cuivre dans la Fabrication des Tubes de Condenseurs de Turbines á Vapeur.) *Cuivre et Laiton*, Vol. 5, Feb. 15, 1932, pages 53-60.

The article gives a general review of the characteristics of condenser tubes, their maintenance and manufacture. The most generally used materials are: Muntz metal, 60% Cu, 40% Zn; Brass, 70% Cu, 30% Zn; Admiralty Brass, 70% Cu, 29% Zn, 1% Sn; Cupro-nickels, now mostly 70% Cu and 30% Ni, which have a better resistance to sea water than the before mentioned materials; Ambrac, 75% Cu, 20% Ni, 5% Zn, or 65% Cu, 30% Ni and 5% Zn; Alumbro, 76% Cu, 22% Zn, 2% Al. The corrosion resisting property of the latter material is particularly great because of the thin oxide film which forms and protects against progressing corrosion. The cleaning of condenser tubes and apparatus for this purpose is also treated. The causes of corrosion can be due to the tubes themselves if the composition is not suitable for the particular case, or external influences, such as chemical action by seawater, or vibrations or stray currents by the formation of galvanic elements. Means for eliminating the latter are described. A list of bibliographical references on general matters and on corrosion is added. Ha (4)

Determination of the Solution Speed of the Different Crystal Faces of Copper Single Crystals. (Bestimmung der Lösungsgeschwindigkeit der verschiedenen Flächen von Kupfereinkristallen.) R. Glauner & R. Glocker (Technische Hochschule Stuttgart) *Zeitschrift für Kristallographie*, Vol. 80, Nov. 1931, pages 377-390.

A method is developed for measuring the solution speeds of any number of crystal faces of different orientation by determining the losses in weight. The solution velocities of 7 crystal faces of Cu single crystals are determined in organic and inorganic media. For a special case, i.e., acetic acid + hydrogen peroxide, the anisotropic behavior of the solution speed is presented by a space model. In many testing solutions the (100) plane showed the lowest solubility, however, a reversion of succession can take place. It is noted that organic acids of the same homological series acted differently in regard to the occurrence of the maximum and minimum of solubility. The influence of contaminations on the solution speed is discussed and proved to depend essentially on the solution media, which are correspondingly subdivided into 2 groups. EF (4)

Corrosion of Copper. (La Corrosion du Cuivre.) L. W. Haase. *Cuivre et Laiton*, Vol. 5, Feb. 15, 1932, pages 61-69.

Corrosion can be due to three causes: 1. free and dissolved gases, 2. organic, acid and basic salts, 3. organic compounds. The three causes and their origin are thoroughly discussed. The formation of protective films, the influence of soldering which can under certain conditions, greatly corrode the copper, application of copper in the canning and preserving industry and requirements from the point of health regulations are treated at great length. Ha (4)

Accelerated Weathering Tests of Soldered and Tinned Sheet Copper. Peter R. Kosting. *Bureau of Standards Journal of Research*, Research Paper 422, Vol. 8, Mar. 1932, pages 365-379.

The pitting and furrowing of tinned and soldered sheet Cu, which sometimes happen when weathered, were duplicated in the laboratory by exposing the Cu to a humid atmosphere, rich in SO_2 and CO_2 at 50° C. or over. The progress of corrosion was followed by means of weight losses, tensile and bend tests. Extensive pitting and furrowing occurred after the tinned and soldered specimens had been heated to high enough temperatures to cause the formation of complex Cu-Sn alloys. Furrowing reduced the strength of soldered joints and impaired markedly the fatigue properties of the Cu as measured by the number of bends needed for failure. Spilt flux may cause pitting of Cu, but the pits thus formed occur under deposits of Cu salts. A red deposit of cuprous oxide was found under these salt deposits if the Cu originally was oxidized. The Behavior of Gold and Its Alloys with Silver and Copper Against Nitric Acid and Sulphuric Acid. (Das Verhalten von Gold und seinen Legierungen mit Silber und Kupfer gegen Salpetersäure und Schwefelsäure.) G. Tammann & E. Brauns. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 200, Sept. 29, 1931, pages 209-231.

The loss of weight of Au or Au-alloyed plates was greatly different according to temperature of the acids, time of action, and percent of Au in the alloy. The various testing methods and the results are described. Ha (4)

Investigations on Soldered Seams of Gold Alloys. (Untersuchungen an Lotnähten von Goldlegierungen.) H. Ziebe. *Deutsche Monatschrift für Zahnheilkunde*, No. 1, Jan. 1931, pages 1-11.

It is important, in order to obtain corrosion-proof dentures to solder only parts having the same gold content as otherwise local elements are formed which lead to corrosion. The use of 16-carat solder should be avoided as it has proved to be non-resistant. Photomicrograph of seams show the difference between good and bad soldering. Ha (4)

The Corrosion of Preserved-Fruit Tins. *Engineering*, Vol. 131, Apr. 24, 1931, page 540.

Abstract of *Special Report* No. 40 of the *Food Investigation Board of the Department of Scientific and Industrial Research* by T. N. Morris entitled: "The Corrosion of the Tin-Plate Container by Food Products." Most of the work was done on mild steel with comparative tests on Armco iron and steel sheets in various stages of manufacture. LFM (4)

Many Factors Affect Action of Milk on Metals. H. T. Gebhardt & H. H. Sommer. *Food Industries*, Vol. 3, Sept. 1931, page 397.

An interim report issued in connection with an investigation on the resistance of metals to corrosion by milk which is in progress at the Wisconsin College of Agriculture. The materials studied were Al, Ni, Cu, Zn, tinned Cu, solder-coated Cu, tinned Fe, galvanized Fe, Allegheny metal, stainless steel, Monel metal, brass and Ni-Cu-Zn alloys. From the results already obtained conclusions are drawn relative to the influence of acidity of the milk, presence of dissolved oxygen, increase of temperature and steam sterilization of the metals. WHB (4)

Cable Research in Germany. *Electrical Review*, Vol. 110, Jan. 15, 1932, page 82.

Abstract of a recently published report on the engineering and electro-chemical work of the German Post-office, which includes an account of the relation between stray currents and electrolytic corrosion. Most of all cable used today in Germany is Pb covered and paper insulated. An example of the rapidity with which an unprotected cable may be destroyed is that of a 2-strand cable of 0.85 cm. outside diameter with a Pb sheath 1 mm. thick, laid in marl soil containing 45% CaO. The cable was useless in 9 months. Type of corrosion can not be satisfactorily decided by electric measurement alone. Formation of Pb Cl_2 is probably the most characteristic chemical change in electrolytic corrosion. Existence or absence of stray currents in, or on, the cable casing does not definitely prove that there has been or has not been electrolytic corrosion. Tests showed that the detection of surface currents in the Pb sheath, even when several milliamps./dm.^{2}, is in itself no proof of the existence of electrolytic corrosion. They show also that the danger zone of stray currents has a radius of 100 m. Intercrystalline fracture, due to vibration mainly, may be overcome by the addition of 1% Sb or 3% Sn. Grain size is an important factor, but even fine-grained Pb is liable to brittleness. Addition of Sn, Sb, and Cd appears to reduce the resistance of Pb to attack by H_2SO_4, but to increase its resistance to the action of weak organic or inorganic acids, such as are likely to be found in soil. MS (4)

Contributions to the Corrosion Problem. (Beiträge zum Korrosionsproblem.) H. Erlenmeyer. *Korrosion und Metallschutz*, Vol. 8, Feb. 1932, pages 29-35.

The first half of the paper deals with the "morphology of the rust process." Many phenomena superimposing on each other in a complicated manner are involved in this process. The auto-colloid catalysis theory of Friend and the differential aeration theory of Evans are touched upon. The writer sets forth to prove why iron is liable to rust to an extent unrivaled by any other metal. The absence of a protective oxide layer is blamed first. The characteristic feature of the surface layer formed on iron during the corrosion attack is, that it contains capillaries through which the corrosion medium is admitted to the virgin metal while the corrosion products are emigrating in the opposite direction. The writer supports his opinion by focusing attention to the climbing of salts noticed at the glass walls containing certain salt solutions. KCl for instance climbs along a glass rod to a height of 60 cm. above the liquid level. Tests are reported studying the behavior of different solutions in this regard. Next the Brechhold phenomenon is discussed, i. e. the total migration of salts to the outside of ceramic bodies soaked with a salt solution, during the drying process. The latter actually does not start at the outside of the body, but in the interior regions. The writer proved the occurrence of the Brechhold phenomenon on rusting Fe by soaking it with $K_4Fe(CN)_6$ in vacuo. The capillary migration does not take place on other metals, since the capillaries are clogged by deposits at an early stage. The second half of the paper treats with the corrodibility of the system cast iron—bronze submitted to accelerated corrosion tests. The commercial importance of this problem is based on the use of bronze for welding cast iron pipes. The testing media were solutions of $Ca(HCO_3)_2$, H_2O saturated with O_2, $CaSO_4$, NaCl + $MgCl_2$, NH_4Cl, and a peat suspension. The e.m.f.'s were determined. The tests proved the appearance of corrosion in the vicinity of the welded areas. The Fe dissolved was determined and compared with the losses of the combination, steel-Monel metal. The ratio was 0.1712 g.Fe (cast iron-bronze) to 0.1383 g.Fe (steel-Monel metal) dissolved during 72 hours from 15 cm.^{2} Fe. Alternating submersion and immersion tests were performed with a testing equipment working on a 3 hours cycle and successively employing 6 different reagents. In addition to this a temperature change from 20 to 60° C. was attained by using air baths. The testing times were 4 and 10 days, the corrosion rate being determined after every 10 days by weighing the samples and analyzing the Fe dissolved. The materials employed were 2 transversely and 2 longitudinally welded samples of cast iron-bronze, pure cast iron and a combination of steel and Monel metal. The latter corroded most severely, but cast iron-bronze is also liable to pronounced corrosion attack. Cast iron with the skin unremoved was scarcely attacked during the first 20 hours, whereupon a marked corrosion started. EF (4)

Thin Films in Relation to Corrosion Problems. U. R. Evans. *Engineering*, Vol. 132, Sept. 18, 1931, page 381; *Steel*, Vol. 90, Jan. 18, 1932, page 29.

The Passivity of Chromium. II. (Zur Passivität des Chroms II.) Erich Müller & Kurt Schwabe. *Zeitschrift für Elektrochemie*, Vol. 37, Apr. 1931, pages 185-197.

The study of passivity in electrolytic Cr was extended to Cr prepared by the thermite process. The latter is more noble than the former. In the passive state a Cr surface is covered with a layer of attached oxide which prevents the action of those acids not capable of penetrating the layer because of the size of their anions. Cathodic polarization forces H-ions through the layer, dissolves the oxide and renders the Cr active. Each acid has a characteristic activation potential. The oxide layer is distended at corners and points and acids may diffuse through and dissolve the oxide. At these points the Cr is active and tends to polarize the whole surface by short-circuiting. The limit of this self-polarization is set by the rate of diffusion of the H away from the point of discharge. Only when this limiting value is greater than the characteristic activation potential of an acid, e. g., HCl, will the acid dissolve the metal. The limiting self-polarization may be increased by rubbing the surface or by raising the temperature. Thus, rubbing electrolytic Cr produces activation at room temperature in *M* HF, HBr, H_2SO_4 and $HClO_4$ but not in *M* H_3PO_4. Ha (4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Contributions to a Systematic Affinity Theory. 56. The Affinity of Rhenium to Sulphur. (Beiträge zur systematischen Verwandschaftslehre. 56. Ueber die Verwandtschaft von Rhenium zu Schwefel. Rheniumheptasulfid.) W. BILTZ & FRIED. WEIBKE. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 203, Dec. 30, 1931, pages 3-8.

The equilibrium diagram Re-S is discussed and Rheniumheptasulphide determined as a stable chemical compound of a density of 4.866 ± 0.006. The similarity to the neighbor elements Os is pointed out. Ha (5a)

On the Mechanism of Eutectoid Change in Copper-Tin Alloys. H. IMAI & M. HAGIYA. *Kinzoku no Kenkyu, Japan*, Vol. 9, Feb. 1932, pages 85-96.

Eutectoid change of Cu-Sn system was observed by means of thermal analysis and the measurement of electric resistance. In tempering the specimens quenched at 700° C., a remarkable heat evolution at 200°, and a marked decrease and also increase of electric resistance at 300° and at 400° respectively were observed. These changes were most remarkable at the eutectoid composition, 27% Sn. The writer ascribed the change to the stepped transformation of β, e. i., $\beta \rightarrow \beta' \rightarrow \beta'' \rightarrow \alpha + \delta$. The change of microstructures was closely observed. The well known martensitic structure, which appears in a hypo-eutectoid bronze quenched at high temperatures, decomposes, by tempering at about 500° C., into finer crystals; the writer considers that the acicular structure is a certain intermediate phase, probably β'. In tempering the quenched specimen at 300 to 350° C., a very clear banded or laminated structure was observed in β matrix; the writer considers it β''. A structure which appears in a quenched specimen between α and β, and changes its color from dark gray to pale brown according to cooling velocity, and discussed on several occasions by Hoyt, Stockdale and Hansen, was clearly explained by the above stepped transformation. Thermodynamics Applied to the Iron Carbon System. F. H. JEFFERY. *Transactions Faraday Society*, Vol. 28, Feb. 1932, pages 98-100.

The differences in deductions based on thermodynamic reasoning between Jeffery and Yap, Chu-Phay are mentioned. The author maintains that the liquid phase in equilibrium with austenite is a solution of C in Fe is the only tenable possibility. Also there is no indication of a "point saillant" at 1020° C. Since thermodynamic equations apply to dilute solutions, further experimental work may modify the curvature of solidus and liquidus between 1130° and 1487° C. (5a)

Science of Metals. VSEVOLOD N. KRIVOBOK. (Carnegie Institute of Technology). *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1143-1146.

Introduction to section on "Metallography," which begins in this issue. Outlines scope of science of metals, which may be divided into 4 fields. These are inspection, "plant research," development of new materials and alloys, and metallography. The last branch strives to answer the "why" questions with regard to the properties, behavior, and applications of metals and alloys. MS (5a)

The Curie Points. L. F. BATES. *Proceeding Physical Society*, London, Vol. 43, Jan. 1, 1931, pages 87-95.

Attention is directed to the fact that at least 3 temperatures may have to be specified in a description of the magnetic behavior of a ferro-magnetic substance. These are termed, respectively: the ferro-magnetic critical point, the ferro-magnetic Curie point and the paramagnetic Curie point. The significance of the relative positions of the last two points is discussed and it is shown that a slight extension of the view that ferro-magnetism is due to magnetic particles consisting of a group of associated atoms may account for the paramagnetic behavior of Fe, Ni and Co and for that of more complicated substances. Ha (5a)

The Diffusion of Tin into Iron with Special Reference to the Formation of Columnar Crystals. C. O. BANNISTER & W. D. JONES. *Engineering*, Vol. 132, Oct. 2, 1931, page 443.

The System Iron—Cobalt—Tungsten (Das System Eisen—Kobalt—Wolfram.) WERNER KÖSTER & WILLI TONN (Dortmund). *Archiv für das Eisenhüttenwesen*, Vol. 5, Feb. 1932, pages 431-440.

Includes 39 diagrams. Review is made of systems Fe-Co, Fe-W and Co-W. The melts of the 3-phase system Fe-Co-W were studied up to the W content of the section Fe_3W-CoW. These 2 compounds form in the ternary system a continuous series of solid solutions. Under this hypothesis the course of the equilibrium was derived and confirmed by means of thermal, dilatometric, and structure experiments, as well as by separation hardening. The 3-phase equilibrium Liquid + W = Fe_3W_2 of the 2 phase system Fe-W decreases with Co addition to somewhat lower temperature and steadily changes over into the equilibrium Liquid + W = CoW. The equilibrium Liquid + α-Solid Solution + Fe_3W_2 of the system Fe-W takes place at still lower temperatures, until at 1465° C. the 4-phase reactions, Liquid + α-Solid Solution $\rightleftarrows$ γ-Solid Solution + δ-Solid Solution, coincides with 3-phase equilibrium of Liquid & α-Solid Solution = γ-Solid Solution of system Fe-Co, whose temperature also decreases with W-addition. Equilibrium of liquid state resulting from reaction Liquid = γ-Solid Solution + δ-Solid Solution is eutectic and is transformed in passing through a minimum temperature value, into the equilibrium, Liquid = γ-Solid Solution + CoW of the Co-W system, while 3-phase equilibrium condition of solid crystal $\alpha + \gamma + \delta$ remains constant up to room temperature. Composition of α- and γ-Solid Solution taking part in this equilibrium remains almost constant with decreasing temperature to approximately 950° C. and is then displaced strongly towards Co side, corresponding to course of the α- γ- transformation in the Fe-Co system. (5a)

The α and β Solid Solutions of the Copper-Zinc Alloys and the Corresponding Liquid Solutions in Equilibrium with them, examined thermodynamically. F. H. JEFFERY. *Transactions Faraday Society*, Vol. 28, May 1932, pages 452-455.

Both liquid and solid phases of the α field, and the liquid phase in equilibrium with mixed α and β phases and with the β phase are solutions of $CuZn_4$ in monatomic copper molecules. The β solid solution consists of $CuZn_2$ dissolved in monatomic molecules of copper. The similarity between the Cu-Sn and Cu-Zn phases as shown by X-ray methods is not substantiated by the thermodynamic method. PRK (5a)

Thermodynamic Considerations of Several Equilibrium Curves of the System Iron-Carbon. (Thermodynamisches Betrachtungen Zu einigen Gleichgewichtskurven des Zustandsschaubildes Eisen-Kohlenstoff.) FRIEDRICH KÖRBER & WILLY OELSEN. *Archiv für das Eisenhüttenwesen*, Vol. 5, May 1932, pages 569-578.

Report 179 of Committee on Materials of Verein deutscher Eisenhüttenleute. Includes 44 references and composite Fe-C phase diagram giving all values from the literature based on temperature and C content. Thermodynamic equations for deriving equilibrium lines in general 2-phase systems are calculated for the Fe-C system. The fusion and transformation lines in 2-phase systems are computed from the heat of fusion and transformation. Heat of transformation of pearlite as calculated was 20.5 cal/g., and the heat of formation of cementite amounts to between -5 and -7 K cal/mol. The major part of the C is dissolved in the melt in the form of iron-carbide molecules. The molecular state of C in γ-solid solutions cannot be definitely ascertained. A bibliography of the literature for the Fe-C system is given for each definite phase of the work. DTR (5a)

Aging Notch Toughness and Strain Figure Etching. (Alterungskerbzähigkeit und Kraftwirkungsfigurenätzung.) H. JUNGBLUTH. *Archiv für Eisenhüttenwesen*, Vol. 4, May 1931, pages 533-536.

Occurrence and causes of strain figures as revealed by Fry's etching method are reviewed. In reporting the results of his own investigations the previous results of Köster (*Archiv für Eisenhüttenwesen*, Vol. 3, April 1930, pages 649-658; see *Metals & Alloys*, Vol. 1, 1930, page 745) are referred to in particular. The author states that from Köster's findings on the relation between strain figure etching and nitrogen segregation the conclusion could be drawn that the aging properties of a material cannot be judged from the etching of strain figures. In checking Köster's tests to suppress the occurrence of strain figures by a suitable heat treatment results were obtained that are only in part in accord with those of Köster. Jungbluth shows that the strain figures can still be revealed in aging-sensible materials by deep etching after the following procedure: Annealing at 100° C. for from 30 to 100 days, cold working and a subsequent 6 hr. anneal at 100° C. The author furthermore shows that even if Köster's observations are correct, the original condition of the material can be re-obtained by annealing the material as delivered at temperatures above A_c ''' . By this normalizing the nitrogen is going again into solution. The aging is then performed in the normal way. 22 references. GN (5a)

Structure & X-Ray Analysis (5b)

Precision Measurements for the Lattice Constant of Columbium. (Präzisionsmessung der gitterkonstante von Niob.) M. C. NEUBURGER. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 197, No. 2, 1931, pages 219-223.

An especially pure sample of Cb was accurately tested by an X-ray method. The results agree with those previously reported. The edge of a cubic body-centered crystal is calculated to be 3.303 ± 0.002 A. U. from which the sp. gr. 8.56 is obtained as compared to 8.55 by direct measurement. Ha (5b)

On the Lattice Constants of Rhenium. (Zu den Gitterkonstanten des Rheniums.) K. MOELLER. *Naturwissenschaften,* Vol. 19, June 26, 1931, page 575.

The lattice constants of rhenium have been determined by a special precision method: a = 2.755 A. U., c = 4.450 A. U. WHB (5b)

An Attempt to Activate Adsorbed Mercury Atoms by Ultra-Violet Light. L. H. REYERSON. *Physics,* Vol. 2, Feb. 1932, pages 70-72.

Mercury atoms adsorbed on catalytically active extralattice Cu atoms are not activated by the light from a mercury lamp sufficiently to cause a reaction to occur between hydrogen and ethylene. Mercury in the vapor state under similar conditions does cause such an action to take place. (5b)

The Determination of the Solubility of Manganese in Magnesium by X-Rays. (Röntgenographische Bestimmung der Löslichkeit von Mangan in Magnesium). E. SCHMID & G. SIEBEL. *Metallwirtschaft,* Vol. 10, Dec. 4, 1931, pages 923-925.

Contains 5 references. The lattice constants of Mg containing from 0 to 2.5% Mn were determined by a precision method. The samples were heated to 600° C. and quenched. To determine the solubility of Mn in Mg, samples containing up to 3.7% Mn were quenched at 600 to 645° C. and reheated to 350 to 635° C. and examined by means of X-rays. The solubility curve drops from the eutectic of 3.4% Mn at 645° C. sharply to practically O at 200° C. Photomicrographs of the 3.7% Mn alloy quenched from 600° C, and reheated to 500° C. are shown. CEM (5b)

A New Graphic Method for Assigning Indices of Powder Photographs. (Ueber eine neue graphische Methode zur Indizierung von Pulveraufnahmen.) E. SCHNEIDER. *Zeitschrift für Kristallographie,* Vol. 78, July 1931, pages 503-510.

A graphic method including a mathematical proof is described confining itself, like the Hull-Davey method, to the special case, that the quadratic form has only two coefficients. In contrast with Hull-Davey, the writer exclusively employs straight lines, resulting in a quick and easy performance of the drawings. EF (5b)

The Transformation of Cobalt. (Über die Umwandlung des Kobalts.) G. WASSERMANN. *Metallwirtschaft,* Vol. 11, Jan. 29, 1932, pages 61-65.

Includes 20 references. Technical Co containing 1.94% Ni, 1.84% Fe and .64% Mn was hot rolled, then cold rolled to .2 mm. thickness. X-ray examination disclosed that it had a hexagonal structure, similar to Mg. When heated to above 450° C. the structure became cubic. The transformation is independent of the time of heating and rate of cooling. The only ways to recover the hexagonal structure are to cold roll again or to anneal at high temperatures, recrystallizing the metal. The transformation temperature was also checked by determining the change in thermal expansion in the Co sheet and in single crystals of technical and c.p. Co. The transformation takes place without any change in the crystal boundaries and can be considered a simple shifting, 2 atoms being included in 1 molecule. Co is suitable for the study of various transformation problems due to the absence of foreign atoms. A transformation point at 1015° C. which has been reported by other investigators does not exist. CEM (5b)

The Influence of the Crystal-Orientation of the Cathode on that of an Electrodeposited Layer. W. A. WOOD. *Proceedings Physical Society, London,* Vol. 43, Pt. 2, Mar. 1, 1931, pages 138-141.

The influence of the crystal-orientation of a cathode on that of an electrodeposited layer is studied by X-ray methods for the cases of Cu and Ni, respectively, deposited on rolled Cu. The conditions of cathode surface and current density which accompany an oriented deposit are determined. The orientation of the Cu deposit for small currents is the same as that of the cathode. The Ni, at low current densities, assumes a distinct orientation. As the current is increased there is a region of no orientation, followed, at still higher currents, by an orientation the same as that of the cathode surface below. Ha (5b)

The Excitation Potentials of Light Metals. H. W. B. SKINNER. *Proceedings Royal Society,* Vol. 135A, Feb. 1932, pages 84-108.

The critical potentials of metallic Li have been determined. They consist of some low-voltage potentials and the critical potentials corresponding to the excitation of Li K-radiation. The radiation emitted by metallic Li has been studied by the photoelectric method. The general characteristics of the spectrum of photoelectrons ejected by the radiation from Li are in accord with those found by Rudberg, by a different method, for other light elements. The photoelectrons which have energy corresponding to only a few volts largely predominate. A numerical comparison is satisfactorily achieved between the observed critical potentials of Li metal and the calculated energy levels of the free Li atom. The existence of a radiation potential for the metal was rather unexpected on account of the fact that the lowest valence states in the metal have to be supposedly filled with electrons; but it is shown that the ionisation of the K-shell alters the levels in the metal in such a way that there are empty levels around the ionised atom into which the K-shell can switch. Though irrelevant to the case of Li it is shown that the effects of the crystal-lattice on the motion through it of (a) the incident electron-beam which is used for the excitation of the radiation, and (b) the electrons which are thrown from a K-, L-, or M-shell in the excitation process, may have an important bearing on the interpretation of soft X-ray discontinuities. It is shown that the true probability for a given excitation process of an atom in a solid varies with the voltage of the exciting electron in a way quite analogous to the variation of the excitation function for the corresponding process in the case of a free atom. (5b)

On a Novel X-Ray Method for Investigating Crystal Lattice Distortions. (Über eine röntgenographische Methode zur Untersuchung von Gitterstörungen an Kristallen.) W. BERG. *Die Naturwissenschaften,* Vol. 19, May 8, 1931, pages 391-396.

Pictures of crystal surfaces are secured by using an X-ray pencil perpendicular to the surface and photographic plate. Those pictures are composed of a system of stripes, which are light and dark. It is shown that stripes resulting from space lattice distortions are encountered parallel to the cubic sides and at 45° to them. The stripes can be obtained artificially by pressure if the internal stresses of the crystals were released by proper heat treatment. In natural crystals stripes due to slip were detected. EF (5b)

X-Ray Analysis of Light Aluminum Alloy Stamping. E. F. BACHMETEW. *Transaction of the Central Aero-Dynamical Institute,* No. 110, 1931, 27 pages. (In Russian.)

Several die forgings of light Al alloys were investigated by X-rays in order to determine the applicability of the method for inspection of light metal forgings. Diffraction method seems to be more promising in the determination of cold work. It gives fuller information than metallographic means but drawing proper conclusions is strongly handicapped by the complexity of the phenomena entering the working o. metals. (5b)

X-Ray Inspection Required for Welded Boilers. RICHARD K. ATKIN. *Machinery,* Vol. 38, Jan. 1932, pages 353-354.

Discusses the regulation of the A.S.M.E. Boiler Construction Code, in regard to X-rays of welds. For all plate thicknesses of 3" or less all welded joints must be X-rayed with apparatus capable of determining quantitatively the size of a defect with a thickness greater than 2% of the thickness of the baseplate. The Robert W. Hunt Co. has equipped a laboratory for this work. RHP (5b)

The Atomic Scattering Power of Iron for Various X-Ray Wave-Lengths. A. J. BRADLEY & R. A. H. HOPE, *Proceedings Royal Society,* Vol. 136A, May 1932, pages 272-288.

An experimental investigation has been made of the atomic scattering factor of Fe using X-rays of different wave-lengths. Powder photographs of the alloy FeAl were made with Mo, Cu, Fe and Cr radiations, and the intensities of the lines were measured photometrically. The reflections are of 2 types, Fe + Al and Fe — Al. It was therefore possible to deduce relative f curves for Fe and Al. By reducing the Al f curve to the same scale as Hartree's f curve, and introducing a temperature factor, the observations were made absolute. By this means absolute values of the atomic scattering factors of Fe and Al were obtained for different values of sin θ/λ. It was found that the f curves for Al overlay almost exactly at all angles; this provides a check on the accuracy of the method. The Fe f values for each radiation were compared with the f values calculated by James and Brindley, using the Thomas method. For Mo and Cr radiation the observed results agree closely with theory between sin $\theta/\lambda = 0.2$ and 0.3. For larger angles the observed values for Mo fall very slightly below the calculated values (about 0.3 units). The f values for Cu, Co and Fe radiations are considerably less than the Thomas values. The difference in f for 2 radiations is almost independent of the angle of reflection. The f values fall in the following sequence: Mo, and Cr, Cu, Fe, Co. The value for Cu is about 0.5 units, for Fe about 1.5, and for Co about 3 units below that of Mo and Cr. The results indicate that away from the absorption edge the Thomas formula is applicable to Fe, but in the neighborhood of the absorption edge the scattering power falls off. The effect is very important at large angles where the f value for Fe is, in proportion, much more seriously diminished than at small angles. WAT (5b)

Cold Rolled Duralumin. E. F. BACHMETEW. *Transactions Central Aero-hydrodynamical Institute,* No. 109, 1932, 40 pages. (In Russian.)

The influence of cold deformation up to 96.3% on duralumin was investigated by mechanical, metallographic and X-ray methods. Sheets were used as samples. Brinell method furnished hardness figures. To about 30% elongation no definite orientation of crystalline units takes place. In the range 30-70% a definite orientation occurs along the axis which can be defined as 38°, 55° and 77° from the edges of the cube [100] [010] [001]. The strength of the metal increases here with the amount of cold deformation. Above 70% the axis of orientation changes towards [111] reaching with 93.6% deformation a position expressed by 46°, 53° and 67°. Structural changes could not be followed by metallographic means but were clearly distinguishable in X-ray testing. (5b)

The Crystal Structure of β-Zirconium. (Die Kristallstruktur des β-Zirkons.) W. G. BURGERS. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 205, Apr. 8, 1932, pages 81-86.

The crystal structure of the β modification of Zr which is stable above 862° C. was determined by X-rays. It was found to be cubic-space-centered with 2 atoms in one elementary cell with $a = 3.61$ A.U. at a temperature slightly above the transformation point. The special camera used in the tests is described. 11 references. Ha (5b)

The Problem of Retarded Phase Changes in Iron-Nickel Alloys. (The High Permeability of Air-cooled Permalloy.) [Zur Frage unterkühlbarer Zustandsänderungen in Eisen-Nickellegierungen. (Die hohe Permeabilität von luftgekühltem Permalloy.)] O. DAHL. *Zeitschrift für Metallkunde,* Vol. 24, May 1932, pages 107-111.

It is found that the changes in magnetic behavior upon heat-treatment of Fe-Ni alloys from 50-90% Ni are accompanied by changes in electrical resistance and strength. Tables and curves are given showing these correlated changes in properties. It is believed that these phenomena are caused by a change in atom arrangement, taking place below 600° C., from a random distribution of atoms to a regular one, similar to that obtaining in the alloy of the composition $AuCu_3$. Compounds $FeNi_3$ and $FeNi_2$ are probably effective. The assumption of Honda that on slow cooling the normal solid solution state obtains, characterized by a low initial permeability, is not confirmed. The magnitude of the changes in properties is influenced strongly by additional alloying elements; the effects of Mn and Si have been studied. The alloy Perminvar is shown to be affected by the type of change described. RFM (5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Investigations on Supra-Conductivity. (Untersuchungen der Supraleitfähigkeit.) W. J. de Haas *et al.* (University of Leyden) *Die Naturwissenschaften*, Vol. 20, Jan. 8, 1932, pages 37-38.

Measurements on single crystals of Sn disclosed an abrupt transition from the normal to the supra-conducting state. A discontinuity otherwise observed is ascribed to defects in the material and to magnetic disturbances. The magnetic boundary value of the supra-conductivity was studied in Pb and Bi. In, Tl and Gr also exhibited the phenomenon of supra-conductivity as well as Th, Ti and Zr. EF (6)

Friction Tests on Bearing Plate Materials. Th. E. Stanton. *Engineering News Record*, Vol. 106, June 25, 1931, pages 1058-1060.

Different Sn bronzes, non-rusting steel and concrete were investigated as material for plates on which the free end of a bridge rested to be able to follow the expansion by heat. The friction coefficient increased very greatly up to 200 strokes per minute, after this only little. Lubricants reduce the friction about 20%, the best lubricant proved to be asbestos packing, especially for the concrete plates. On the basis of these tests the laboratory of highways in California adopted a soft Pb-bronze of 78.5 to 87.5% Cu, 9 to 11% Sn, 9 to 11% Pb, 0.05 to 0.25% P and 0.75% Zn for such plates with asbestos packing. Ha (6)

Hardness of Chromium as Determined by the Vickers-Brinell, Bierbaum and Mohs Methods. R. Schneidewind. *Transactions American Society for Steel Treating*, Vol. 19, No. 2, 1931, pages 115-140.

Notch Effect on Deflection Rods. (Kerbwirkung an Biegestäben.) E. Siebel. *Stahl und Eisen*, Vol. 52, May 19, 1932, pages 494-495.

In the vicinity of a notch or indentation in a bar, rather high local stresses are set up and it is only in a few cases that it is possible to determine all existing stresses with certainty. G. Fischer used elongation measurements over the entire length of a bar as an indirect measure of distribution of stresses. From graphs showing % elongation against increasing notch radius with constant notch or indentation depth, also % elongation against varying notch depth with constant radius, for both round and semi-cylindrical notches, it may easily be seen that the maximum elongation occurs at the center of the notch, with steep slopes up to and away from the maximum. The maximum values for elongation drop with decreasing depth of nick and increasing radius of notch, the curves flattening out similarly. Notch number α_k is given for varying notch depths from 0 to 25 mm. and radii from 0 to 25 mm. DTR (6)

New Machining Methods. (Neues Zerspannungsverfahren.) O. P. van Steewen. *Maschinenkonstrukteur-Betriebstechnik*, Vol. 65, Jan. 10, 1932, pages 3-4.

A new kind of rigid automatic machine made by the Loewe Gesfürel A.-G. according to the Mulka patent operates in a way opposite to the rotating method usually used where the piece turns longitudinally. Here the piece travels along, being punched from 4 directions, 90° apart, at once, by a part which extends the whole length of the test piece. Time is saved, and also, more satisfactory operation is accomplished since the 4 punching meters wholly support the test piece, preventing the occurrence of vibrations. MAB (6)

Two Kinds of Elongation Discriminated in Plastic Deformation of Metals. Ryuzaburo Taguti. *Scientific Papers Institute of Physical & Chemical Research*, Vol. 18, Apr. 1932, abstract page 60.

By the photoelastic method of studying deformations within the elastic limit the cracks occurring in the material in the district of the strain figures and elsewhere seem to point to different kinds of elongation. Tests were made on brass, Al, Zn, Ni and other metals. An explanation on the basis of the crack analysis is attempted. Ha (6)

Modern Practice in Cast-Iron Testing. H. W. Swift. *Foundry Trade Journal*, Vol. 46, Mar. 17, 1932, pages 173-175; Mar. 24, 1932, pages 187-190.

Discusses the British, American, German and French standards for the testing of cast Fe in some detail, following this discussion by consideration of the choice of testing methods suitable for particular cases. The importance of the mass effect upon the mechanical properties of the test pieces and the necessity for careful methods of sampling are referred to. A very full discussion of tensile, transverse, shear, hardness, and impact tests concludes the paper. OWE (6)

The Wear of Cast Iron. A. A. Timmins. *Foundry Trade Journal*, Vol. 46, Apr. 7, 1932, pages 216, 223.

After discussing various methods of testing wear, the author deals with the various explanations which have been put forward for the resistance of cast Fe to wear. The importance of the phosphide eutectic in this connection is dealt with at some length, and the influence of glazed surface on cast Fe is referred to. The article is accompanied by 2 photomicrographs. OWE (6)

Tests of Alloy and Heat Treated Carbon Rail Steels. J. B. Young. Appendix K to report of Rail Committee. *Bulletin American Railway Engineering Association*, Vol. 33, Feb. 1932, pages 573-576.

A considerable number of transverse fissures, and split and crushed heads, are reported in intermediate Mn rails now in experimental use. The fissure failures appear to be due to a martensitic structure in the head of the rail. Over 700,000 tons of such rails are in American track. Compositions varying slightly from those previously used are being tried out. Only 5,000 tons of heat-treated rails were purchased in 1931, most of these going to the Pennsylvania, the balance to the C. & O. and the Reading. Several heat-treated rails laid in 1931 developed head failures due to quenching cracks, so that all the rails were returned for a proof test, in which the rail is passed between staggered rollers so that the rail is bent nearly to its elastic limit. Under this test, cracks or quenching strains will cause the rail to break, so that those passing the test are expected not to show premature failure in service. HWG (6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A.S.T.M. Research Committee on Fatigue of Metals.

The Behavior of a Single Crystal of Aluminum under Alternating Torsional Stresses While Immersed in a Slow Stream of Tap Water. H. J. GOUGH & D. G. SOPWITH. *Proceedings Royal Society*, Vol. 135A, Mar. 1932, pages 392-411.

The tests involve the study of a single crystal only. The effect of the intercrystalline boundary and crystal size on corrosion-fatigue form the subject of further investigations not yet completed. No effort is made to correlate the results of the present work with those previously obtained in tests on crystalline aggregates by other workers. One very important aspect, however, may be remarked. Arising from tests made on crystalline aggregates, the opinion has been expressed that failure by corrosion-fatigue is due primarily to the stress-concentration effects caused by corrosion pits or notches due to general or local attack. But the present results show that, as far as a single crystal is concerned at any rate, this is not the case, but that the cause of failure is directly related to the crystalline structure. This is the more satisfactory explanation, as failure under ordinary fatigue and corrosion-fatigue conditions are now shown to be directly related. Many fatigue experiments on single crystals of Al, Fe, Ag, etc., have shown that fatigue cracks always originate in regions which have been plastically deformed thus leading to the conclusion that fatigue failure, in such cases, is a consequence of the break-up of the crystal structure resulting from slip. If, as in corrosion-fatigue, a corrosive action is superimposed on the stress effects applied in ordinary fatigue tests, it would appear most probable that these actions would be mutually accelerative, and that failure would; in this case also, be most marked in the plastically deformed areas. The present experiment has shown that this actually occurs, and this result is of great importance as affording some fundamental information regarding corrosion-fatigue phenomena which could only be obtained from single crystal tests. A corrosion-fatigue test on a single crystal where the applied cycle of stress is such as would not normally produce plastic deformation would afford an interesting comparison with the present experiment. A crystal of Fe would be suitable for this purpose, and it is proposed to carry out an experiment on such a crystal. WAT (6f)

Accelerated Cracking of Mild Steel (Boiler Plate) Under Repeated Bending. W. ROSENHAIN & A. J. MURPHY. *Engineering*, Vol. 131, May 22, 1931, page 680.

Abstract of paper read before the Iron & Steel Institute, London, May 1931. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 247. LFM (6f)

The Failure of Steel Components by Fatigue. H. W. KEEBLE. *Iron & Steel Industry & British Foundryman*, Vol. 5, Jan. 1932, pages 165-170.

11 references. A consideration of the causes of fatigue failure in which the discussion of the most prolific cause of failure, namely, stress localization, is divided into treatments of the effect of surface condition, of design and of the material. A fine surface finish, the use of generous fillets, and the use of clean steel will bring about a decrease in the number of fatigue failures. CHL (6f)

Steady Torsion Combined with Alternating Bending. J. B. KOMMERS. *Engineering*, Vol. 132, Aug. 28, 1931, page 249.

Equations are given for developing the criterion for determining what value of constant shear stress may be combined with a given value of alternating tensile and compressive stress, so that the fluctuations of stress on any inclined plane shall not exceed the value *a* defined in the following equations.

$$a = S_{-1}\left(1 - \frac{S}{u}\right) \text{ when S is tensile stress}$$

$$a = S_{-1}\left(1 - \frac{2S}{u}\right) \text{ when S is compressive stress}$$

a = the alternating unit stress, or semi-range of stress;
S_{-1} = the endurance limit for completely reversed tensions and compression;
S = steady stress, or mean stress, which equals the maximum stress plus the minimum stress divided by 2.
u = ultimate tensile strength. LFM (6f)

Influence of Direct Current Magnetizing on Damped Materials during Rotary Oscillations. (Einfluss der Gleichstrom-Magnetisierung auf die Werkstoffdampfung bei Drehschwingungen.) A. ESAU & H. KORTUM. *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 2, Dec. 1931, pages 429-434.

Describes the test set-up and gives the results of tests with a) rolled Fe, b) electrolytic Fe, c) steel, d) alloy steel, e) Ni, f) Fe-Ni alloy. The conclusion arrived at is that the influence of magnetizing is very marked on the materials tested. In Fe and steel a decrease in damping, which approaches a limit (saturation) more or less rapidly, takes place up to a certain deformation. In Ni and in an Fe-Ni alloy an increase and then a decrease in damping occurs. The difference between Fe and Ni, however, appears to be only quantitative, since in Fe the change proceeds in a similar way only with greater deformation. The damping curves of pure metals indicate extreme values or a turning point without magnetization. These extreme values vary with increased magnetization. Annealed and unannealed electrolytic Fe shows similar qualitative damping changes. Variations in frequency appear to follow the same laws as those for variation in damping. MAB (6f)

American Views on Life and Accuracy of Springs for Measuring Instruments. (Amerikanische Anschauungen über Lebensdauer und Genauheit von Federn von Messgeräten.) F. MOELLER. *Die Messtechnik*, Vol. 8, Feb. 1932, pages 32-34.

Recent American investigations of fatigue phenomena and the corresponding endurance strength are reviewed and for a series of ferrous and non-ferrous materials numerical values of the endurance strength are given. The concepts of dynamic formability, hysteresis and creep are defined. The experiments of Sayre and the dependence of the elasticity modulus on the stress resulting from them are discussed. 20 references. Ha (6f)

Fatigue Fractures and Fatigue Strength. (Dauerbrüche und Dauerfestigkeit.) R. MAILÄNDER. *Krupp'sche Monatshefte*, Vol. 13, Mar. 1932, pages 56-81.

The characteristic signs of fatigue fracture, the nature of fatigue strength and the methods for their determination are discussed from the point of view of the operating and designing engineer. From numerous investigations a diagram is developed which shows the average bending-vibrating strength as a function of the tensile strength. Another diagram gives the fatigue strength for other types of stresses. The fatigue strength of ordinary structures can be easily determined by means of these curves; the actual determination of the fatigue strength by tests is very expensive and pays generally only for high grade materials which must be utilized to the extreme limit. If that is done, the value thus obtained must still be modified by taking into account the influence of machining methods. How this can be done is briefly explained. A number of failures is shown in photographs and the reasons for them pointed out. Ha (6f)

Endurance of Light-Metal Sand-Cast Alloys. (Die Dauerfestigkeit der Leichtmetall-Sandguss-Legierungen.) W. SARAN. *Mitteilungen der deutschen Materialprüfungsanstalten*, 1932, No. 12, page 184.

Abstract. For abstract of original article see *Metals & Alloys*, Vol. 2, Oct. 1931, page 215. HWG (6f)

The Spring Problem in Vehicles. (Das Problem der Fahrzeugfederung) *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Apr. 10, 1932, pages 196-197.

The article deals in particular with the testing of springs, describes and illustrates new machines for dynamic spring testing and calls attention to the problem of fatigue in general. GN (6f)

Finishing (Feinbearbeitung). *Schweizerische Technische Zeitschrift*, Vol. 29, Mar. 10, 1932, pages 144-146.

The article deals with 3 various possibilities of finishing machined parts: (1) finishing with diamond or hard metal tools, (2) grinding or polishing, (3) pressing of the surface, as it has been suggested by Föppl in order to increase the mechanical properties. The last method is particularly suitable to increase the fatigue properties. GN (6f)

Measurement and Indication of Internal Energy Absorption of Materials. (Messung und Kennzeichnung der inneren Arbeitsaufnahmes von Werkstoffen.) WILHELM SPÄTH. *Archiv für das Eisenhüttenwesen*, Vol. 5, May 1932, pages 587-590.

When a material is periodically worked between 2 limiting values in definite time periods, a certain part of the applied energy is consumed in each cycle of the load, the amount of this energy or work used up varying largely with limiting values of the load applied and with a number of other conditions. The consumption of energy is tied up with fatigue or endurance properties of materials. One of the oldest methods for determining the consumption depended on measurement of the temperature rise, which resulted under repeated loadings. A calorimetric evaluation in heat units or watt-seconds was the determination, which was converted into a volume or weight unit of the material. In this paper an electrical study was made of insulating materials, in which hysteresis and phase curves were plotted. The equation $N = 1/2\ P.V.\delta$ was derived in which δ denoted the phase angle between total force P and amplitude A, also $V = A \times W$, where W denotes frequency. Maximum instead of average values are used for stress P and velocity V. The angle δ has been designed as "Angle loss" and specifies the phase displacement which takes place in a test piece between the Sine curve—fluctuating load and the resultant change in form produced thereby. The angle loss is independent of the dimensions of test sample and offers a comparatively simple method of calculation for permanently or continuously loaded materials. Its value varies theoretically between 0° and 90° or between 0 and $\frac{\pi}{2}$. This method is an advantageous one, since it gives energy loss during an entire fatigue or endurance test. A simple measuring device for torsion vibration testing is described. DTR (6f)

Plastic Strain in Relation to Fatigue in Mild Steel. B. P. HAIGH & T. S. ROBERTSON. *Engineering*, Vol. 132, Sept. 18, 1931, pages 389-390.

Reports fatigue tests on specimens of steel of chemical content 0.16 C, 0.18 Si, 0.75 Mn, 0.053 S and 0.033 P. The endurance limit under completely reversed axial load was found to be 31,000 lb./in.². In a second series of these the endurance limit was found for a range of stress from 25,000 lb./in.² compression to 40,000 lb./in.² tension. Tests were made on specimens 0.5" diameter in each of which had been bored a radial hole .031" diameter. Endurance limits were found for completely reversed stress at 17,000 lb./in.² and for a range of stress from 1000 lb./in.² compression to 28,000 lb./in.² tension—about half the strength for unpierced specimens. For the particular steel tested the tests indicate that a superposed steady stress up to 8000 lb./in.² has little effect on the critical *range* of cyclic stress for the metal. 2 special experiments gave some indication that the disturbance caused by the early stages of plastic strain reduce the resistance of the metal to repeated stress, at least when fatigue tests follow immediately after plastic strain. After a period of rest this reduction of fatigue strength by plastic strain was found to be less. HFM + LFM (6f)

Suggestion for the Fixation of the Permissible Stresses in Mechanical Engineering. (Vorschlag zur Festlegung der zulässigen Beanspruchungen im Maschinenbau.) FR. P. FISCHER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, May 7, 1932, pages 449-455.

The most recent results of investigations of alternating stresses have shown the necessity for making new specifications for admissible stresses. It is suggested to express the permissible stress as a function of the alternating bending strength of a polished sample and of the tensile strength, and to take into account practical conditions of the individual case by reductions from this value. Examples show how this method works out in comparison with the older, mostly static methods of determining the permissible stress. Ha (6f)

The Structure of Electrodeposited Metals III. Leslie B. Hunt. *Metal Industry,* London, Vol. 40, Jan. 8, 1932, pages 40-42.
A discussion of various theories regarding the mechanism of metal deposition and the effect of current densities on the structure. PRK (7a)

Modern Nickel Plating. (Neuzeitliche Vernicklung.) Herbert Kurrein. *Chemiker-Zeitung,* Vol. 56, Feb. 3, 1932, pages 93-94; Feb. 10, pages 114-115.
The presence of H has a large influence on the quality of Ni plating. H alloys with Ni, hardens and embrittles it. H also diffuses from the Ni into the Fe. The formation of H in the bath and absorption in the Ni deposit depends on the current density, acidity and conductivity of the salts and the pH of the solution. An ammeter and pH determinations are essential to satisfactory plating. Electrolytic Ni gauze anodes give best results. For still baths used at ordinary temperatures the pH should be 5.8 to 6.2, for hot, concentrated baths 4.8 to 5.3. The addition of HNO_3 up to .085 g. per L. or $KMnO_4$ up to .175 g. per L. helps to keep down H formation. The Fe content should not be over .60%. The Ni must cover the Fe or brass completely and be free from pin holes because it is electro-positive to both Fe and Zn. The minimum thickness of the deposit should be .025 mm. For still, cold baths 0.5 amp./dm.^{2} for 4 hours should be used. These have been largely replaced by solutions of 250 g./L. Ni_2SO_4 at 1 to 2 amps./dm.^{2} and 30° C. or 450 g./L. Ni_2SO_4 at 4 to 10 amps./dm.^{2} and 45 to 55° C., the latter with circulation and filtration of the solution. The anodes should be of high purity and solubility. Good control of all variables and frequent and rapid tests are necessary. Automatic temperature control is desirable. The hardness of electroplated Ni has been determined and varies from 155 to 420 Brinell. Brittleness and tensile strength tests have been devised but are not often used. The usual tests consist of salt spray and thickness determinations. As a preliminary coating for Cr, Ni plating must be of good quality. Al and its alloys must be roughened by etching before Ni plating. When plating Zn high current density must be used at the start. Ni-Cu and Ni-Co alloy coatings can now be plated. CEM (7a)

Effect of Concentration of Electrolyte on the Formation of the Anodic Film on Aluminium. Shoji Setoh & Akira Miyata. *Rikagaku-Kenkyusho* (Bulletin of the Institute of Physical & Chemical Research), Vol. 11, No. 2, 1932, pages 317-382.
Gives results of theoretical investigations into the phenomena in the electrolytic preparation of the oxide coating on Al in oxalic acid solutions. Conclusions are as follows. Greater part of the terminal voltage is taken up by the "Active Layer" of the anode, which consists mainly of Al_2O_3 and of pores filled with oxygen. The oxide coating obtained is the residue of it. The thickness of the layer is proportional to the voltage drop in it, irrespective of other conditions. When the concentration, the temperature and the current density are kept constant, the thickness increases with time until a certain point is reached, after which the rate of increase becomes much retarded. The voltage corresponding to this point is called the critical voltage and the quantity of electricity that has passed through unit area of the anode by that time is constant, being independent of the concentration and the current, but it increases with rise of temperature. The higher the concentration and the temperature are, the thicker is the active layer and the more resistant is the coating thereby produced against chemical actions. Judging from the thickness of the active layer, the diameter of the particles which constitute the oxide coating is presumed to be of the order of 10^{-5} - 10^{-6} cm., which is nearly in the same order as colloid particles. The volume of oxygen evolved is proportional to the product of the critical voltage and the square of the current density. This implies that there exist cylindrical pores in the active layer of which the cross sectional area is proportional to the current density and that the oxygen fills it up successively with the growth of the layer. In the case of a.c. the thickness of the layer is smaller than that corresponds to its maximum voltage. The active layer is more fragile when subjected to an electric field and at higher temperatures, it is so even when the field is absent. The apparent specific gravity of the oxide coating is nearly 3.0. The current efficiency of the formation of the coating is best at 15 ma./cm.^{2} or, if current is kept constant, at 50 to 60 volts, amounts to 80%. Prolonged electrolysis lowers the acidity until $Al(OH)_3$ precipitates out, the coating obtained resembling a white enamel and necessitating a high voltage to be applied. Too concentrated solution is unfavorable as the oxalic acid deteriorates and the coating obtained assumes a yellowish color. YO (7a)

Preparation of Steel Prior to Electroplating. G. B. Hogaboom. *Monthly Review, American Electroplaters Society,* Vol. 19, Jan. 1932, pages 26-39; *Metal Industry,* N. Y., Vol. 30, Feb. 1932, pages 59-61.
Includes discussion. Paper before Philadelphia Branch Annual Meeting, Nov. 21, 1931. For cold rolled or polished steel, a 37% H_2SO_4 is used with steel parts as cathode, 1-3 min. is required. For removing scale from hot rolled or forged steel, a special process called Hanson-Munning Bright Dip is used, which removes scale, dirt and tarnish in 3-5 min. Composition of the special bright dip is not mentioned. PRK + LCP (7a)

On the Throwing Power of Electroplating Solutions. Seiji Kaneko. *Journal Society of Chemical Industry,* Japan, Vol. 35, Apr. 1932, page 146B.
The author defines the throwing power of solutions with formulae obtained from calculations in which he uses the quantity of metal deposited in unit time, the distance between the electrodes, the current density at the cathode, the current efficiency, and the voltage drop at the cathode as his factors. Electrometallurgy (7b)

The Development of Electrolytic Metal Extraction Processes at the Norddeutsche Affinerie at Hamburg. (Le developpment des procedes electrolytiques d'extraction des metaux a la "Norddeutsche Affinerie," a Hambourg.) Walter Schopper. *Journal du Four Electrique,* Vol. 41, May 1932, pages 171-179; *Metallgesellschaft,* Apr. 1932, pages 29-39.
Electrolytic separation of Cu began at this plant in 1871 and gradually expanded until now the Cu refining department comprizes 1252 cells and had an annual production in 1930 of about 70,000 tons. The use of superimposed alternating current for electrolysis of Au proposed by H. Wohlwill eliminated troubles of anode coating so that at present on refining 98% Au the plant obtains 2-3% of the precipitates and 3-4% of anode mud. The usual production was about 3000 kg. of fine Au per month but at the present it has dropped to 500 kg. per month. Ag is refined by a special method developed at the plant and the installation was capable of daily production of 1200 kg. of refined Ag though at the present only 140,000-150,000 kg. are refined a year. Electrolytic refining of bismuth from HCl solution began in 1898 and at the present the plant makes more than 2500 kg. Bi per month. It was found that instead of segregation of small amounts of Bi produced during different refining operations it is more advantageous to alloy them as soon as produced with Pb until the Bi content is 0.8-1.0% and then to electrolyse the Bi. Slimes containing all Bi are cast into anodes for Bi electrolysis. Pb refining plant has a capacity of 150-200 tons a month. Sb is refined in concentrated H_2SO_4 bath to which is added antimony fluoride and HF producing Sb 99.8 pure. A secret process for Cd refining produced 39.3 tons of Cd in 1930-31. Ha + JDG (7b)

Metal Reclamation. C. Campbell. *Electrical Review,* Vol. 109, Dec. 25, 1931, page 961.
Describes electrolytic recovery of precious metals from rich Cu bullion. Electrolysis is conducted in Pb-lined earthenware troughs, several being employed. Surplus electrolyte flows into an adjacent Pb-lined wooden box. It is necessary to maintain a constantly flowing and heated electrolyte, containing 10% H_2SO_4 and 4% Cu. Anodes, consisting of the Cu bullion, are arranged in line throughout the troughs, about 1.5" apart from the cathodes, consisting of Cu sheets. The troughs are rectangular where the anodes and cathodes are inserted, but below this level, taper to a point in the center at the bottom where a large glass bottle is connected. Temperature of bath is 50° C., and a c. d. of 10 amp./ft.^{2} is used. If much Ag is present, a little HCl is added to the bath. In about a week the electrolysis is stopped and the cathodes are removed. When all suspended matter has separated out, the anode slimes are run into the bottle below. The sediment, plus what Cu liquor is present, is emptied into an earthenware vessel and boiled with a little NaCl, settled, filtered and dried. Its composition varies, but the following is typical: Insoluble, 5%; Pb, 10%; Cu, 6%; Zn, 15%; Fe, 0.4%; Sn, 15%; Ag, 5-20%; Au, 6-15%, and Pt, 0.01-0.6%. The slimes are thrown on to molten Pb in a furnace, the remainder of the process being purely metallurgical. Cost of process quite small. MS (7b)

Studies in Electrolytic Zinc. I. Purification from Nickel (Studi sugli elettroliti per zinco. I. La depurazione dal nichel). L. Cambi & V. Toja with F. Cremascoli. *Giornale di chimica industriale ed applicata,* Vol. 14, Mar. 1932, pages 125-129.
Ni and Co, harmful elements in the deposition of Zn, are found in Monteponi calamines. The ore from Campo-Pisano, for example, carries 20% Zn and 0.005% Ni, in an oxidized form, probably as a silico aluminate, which is soluble in dilute H_2SO_4. The Ni is best removed by precipitation with Zn dust. The precipitation is activated by As, and the activation is more effective in presence of Pb or Hg, i.e., metals of high hydrogen overvoltage. Some hydrogen compound of As is thought to react with the Ni, precipitating a mixture of As and Ni. In treating an impure electrolyte containing in g./L., about 63 Zn, 40 Cd, 0.2 Cl, 0.3 Mn, and in mg./L., about 15 Ni, 21 Co, it was found that adding 3.2 kg. Zn dust and 80g. Na_2AsO_4 per m. of electrolyte, at 50°-80° C. precipitated about 14.5 mg./L. of Ni in 2 hours. Without the arsenate only about 8 mg./L. precipitated in 6 hrs. Ni is more harmful than Co, as Ni in the deposit greatly increases the attack by the electrolyte upon the Zn deposit. Co may be separated by $KMnO_4 + Zn\ (OH)_2$, or by nitroso-beta-napthol. HWG (7b)

The Electrolytic Production of Metallic Antimony from Ores. (Elektrolytische Gewinnung von Metallischem Antimon aus Erzen.) N. A. Isgarischew & S. A. Pletenew. *Zeitschrift für Elektrochemie,* Vol. 37, July 1931, pages 363-365.
An improved process for the cathodic production of electrolytic Sb was developed. By the electrolysis of solutions made of pure chemicals knowledge was obtained which made practical the production of Sb from the leached-out products of Sb ore, forming a thick deposit of the metal on the cathode. The process is continuous; the electrolyte alternately passing through the cell and over the ore is thus constantly regenerated. Arsenic in small amounts in the raw material is not separated with the Sb. Ha (7b)

Recent Developments in Electrolytic Spelter. Arthur Zentner. *Mining Journal,* London, Vol. 177, May 21, 1932, page 342.
The increase in electrolytic Zn annually from 1920 to 1930 is shown. The individual electrolytic plants in the U. S., Canada, Europe, Australia and Africa and their capacities are very briefly considered. The present technical condition of the industry is described. AHE (7b)

Contributions to the Study of Chemical Reactions in Concentrated Electrolytes. The Vanadic Acid Reduction by Means of Hydrogen Bromide and Its Course in Concentrated Electrolyte (Beiträge zum Studium chemischer Reaktionen in konzentriertem Elektrolytmilien. Die Vanadinsäurereduktion mittels Bromwasserstoff und der Verlauf in konzentriertem Elektrolytmilien). M. Bobtelsky & S. Czosner. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 205, May 3, 1932, pages 401-413.
The reduction of vanadic acid by the hydrogen halides was investigated and found that it is a time reaction which becomes measurable only under definite conditions. The applied methods are described and the influences of concentration of the reducing agents on the speed of reaction determined. Ha (7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

The Parker Process for Rust Proofing. O. W. Roskill. *Industrial Chemist,* Vol. 8, Feb. 1932, pages 59-61.

Prevention of corrosion of iron and steel may be divided into two classes: (a) those which depend on covering the surface of the article with a layer of corrosion-resisting material, or (b) formation of a similar layer by chemical interaction of the iron with the reagent employed. Parker process depends on formation of insoluble phosphates on iron surface by using a bath of dihydrogen phosphate of the formula $M(H_2PO_4)_2$, some free phosphoric acid and some ferrous mono-hydrogen phosphate. The metals (M) of the $M(H_2PO_4)_2$ found suitable were Fe, Zn, Mn and Cd; the number of possible metals being limited owing to the facts, first that they must be more electro-positive than iron, and secondly that they must form phosphates similar in nature to ferrous orthophosphate. Methods of preparation of these phosphates are described. A mixture of manganese and ferrous phosphates was found more satisfactory than the use of ferrous salt alone. Optimum ratio of Fe to Mn for maximum rust protection found to be 1:1. Condition of surface to be treated is important factor, pickling and sand blasting being resorted to on smooth surfaces. The chemical action can be accelerated by presence of a small quantity of copper phosphate. The resultant coating forms excellent base for paints, enamels and even for electroplating. The term "Bonderizing" is used when the preliminary accelerated phosphate treatment is applied to act as a base for paints or lacquers. Costs of Parkerizing probably lower than those of any other method of protection of similar efficiency. (8)

The Attack on Mild Steel in Hot Galvanizing. Edward J. Daniels. *Engineering,* Vol. 132, Oct. 9, 1931, pages 479-480.

Condensed from paper read before the Institute of Metals, Zurich, Sept. 1931. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 12. LFM (8)

Surface Coatings for Aluminum Alloys. W. H. Mutchler (U. S. Bureau of Standards). *Metals & Alloys,* Vol. 2, Dec. 1931, pages 324-330.

25 references are cited. The wide use of wrought Al alloys for aircraft construction has led to work on protection against corrosion by sea water. The author reports on 3 types of coatings: oxide, metallic and organic. A film of oxide forming naturally on Al will protect it against ordinary atmospheric corrosion but salt water and spray produce an embrittling corrosion of these light alloys in spite of the naturally formed coating. An oxide protection may be produced of sufficient thickness to protect, by electrolytic methods where the alloy is made an anode in a plating bath until sufficient oxide coating is obtained. Purely chemical means, simple immersion to produce an oxide coating, is not satisfactory. Several methods and baths for carrying out this process are described. Metallic coatings most satisfactorily applied and offering the best protection are Al, Zn and Cd which may be electroplated, applied by metal spraying or alloyed in the metal. The advantages of paints, varnishes, etc., of low cost and ease of application are discussed and compared with their disadvantages of permeability by moisture, mechanical injury and susceptibility to deterioration by sun and weather. Asphalt type paints are most durable and impervious. The variety of types of coating applicable to this problem make for increased possibilities of combinations for decorative or economic reasons. Some such combinations are discussed. WLC (8)

Magnesium Alloy Protection by Selenium and Other Coating Processes. G. D. Bengough & L. Whitby. *Institute of Metals, Advance Copy* No. 587, Apr. 1932, 12 pages.

Coatings suitable for protecting Mg Alloys from salt water corrosion were studied. Mg is readily coated. A coating of Se was found to be effective. It could be applied by immersion of the alloys in a solution of selenious acid, sodium selenite and NaCl. The coatings were tested in a salt-spray apparatus. The Se coating was found to be self-healing. It does not produce an appreciable dimensional change when applied. Additional corrosion resistance can be secured by painting the Se coated alloys; further work is being done towards developing satisfactory paints. The properties of Se are discussed in an appendix. It is concluded that the toxicity of Se compounds has been overestimated. 12 references. JLG (8)

The Determination of the Porosity of Tin Coatings on Steel. D. J. MacNaughtan, S. G. Clarke & J. C. Prytherch. *Iron & Steel Institute, Advance Copy* No. 11, May 1932, 16 pages.

The holes in Sn coatings could be observed by subjecting samples to a hot-water treatment which caused adherent rust to form at each hole. It was necessary to thoroughly clean the samples prior to the hot-water treatment. This was accomplished by swabbing with chloroform or carbon tetrachloride and finally treatment with acetone vapor. Samples were immersed in water just below its boiling point for 6 hrs. The pH of the water should be between 7 and 4.5. The water did not discolor the Sn and apparently caused rust to form at each hole. The compound $FeSn_2$ was not attacked by the water. The ferricyanide tests and various modifications of this test were studied. The addition of small amounts of NaCl causes the blue compound to appear at the pores in the immersion test. When used by applying paper saturated with ferricyanide to the specimen, NaCl also promotes the formation of blue spots. The ferricyanide test was not suitable for testing tinplate that had been cold worked, but the hot-water test was. Illustrations showing the results of the tests on several grades of plate are included. 6 references. JLG (8)

Simple Deposition of Reactive Metals on Noble Metals. A. S. Russell. *Nature,* Vol. 127, Feb. 21, 1931, pages 273-274.

U, Ti, W and Mo are deposited on a Hg surface, as expected according to the Nernst theory of electrode potential, when acidified solutions of their salts are shaken with Hg amalgam. The presence of the very slight concentration of metal is detected by their catalytic effect on the evolution of H_2 from H_2SO_4 solutions by pure Zn. The deposited metals are quite insoluble in Hg. Ha (8)

INDUSTRIAL USES & APPLICATIONS (9)

Some Recent Developments in Welding for the Chemical Industry. F. Leverick. *Welder,* Vol. 3, Jan. 1932, pages 14-18.

With the arrival of stainless and corrosion-proof steels the use of welded steel containers has greatly increased in the chemical industry. 3 types of corrosion occur which affect the welded vessel and therefore the welder: (1) the direct attack on the vessel by the contained liquid, (2) the effect of dissimilar metals in intimate contact, (3) the effect of small holes or pits. Corrosion of the first type cannot be avoided by the welder; the weld should be well built up and undercuts avoided. In the second case, corrosion is caused by one of the metals dissolving in the liquids, the 2 different metals are the stainless steel of the tank and the mild steel of the weld. so that electrolysis can take place. Holes or pits set up corrosion because the liquid in them will soon have a different oxygen content from the rest of the liquid and thus form a small electric cell. The 3 reasons are discussed in detail and their avoidance emphasized. Ha (9)

Aluminum and Its Alloys in Structural Buildings. (Aluminium und seine Legierungen im Bauwesen.) H. Landgrebe. *Bauwelt,* Vol. 22, 1931, pages 957-958.

How Wire-Rope Construction Affects Selection. A. S. Rairden. *Engineering News-Record,* Vol. 108, Feb. 25, 1932, pages 287-291.

The manufacture of wire rope is subdivided into 3 main operations: (1) spooling, (2) stranding, and (3) closing. Each of these operations is outlined and discussed. Wire rope types and terms relative to them are defined. A tabulation of the common wire rope types listing them in order of their resistance to wear and giving the common field applications of each type is included. CBJ (9)

Platinum in Electrochemistry (Platin in der Elektrochemie). K. Arndt. *Siebert Festschrift,* 1931, pages 1-11.

Of technical, chemically pure and "physically pure" Pt used as anode in 50% H_2SO_4, the first was the least attacked. This is ascribed to a finer structure due to presence of small amounts of other elements. No information is given as to the actual composition of the material used. HWG (9)

The Heat Treatment and Use of Aluminum Alloys for Aircraft Structures. Robert J. Anderson. *Fuels & Furnaces,* Vol. 9, Nov. 1931, pages 1243-1250.

Al alloys have almost entirely superseded wood and fabric in construction of aircraft, both of the lighter- and heavier-than-air types. Only by suitable heat treatment and aging is it possible for metal alloys to meet the requirements of high strength combined with light weight. Chemical composition and physical properties of the most-used Al alloys are given and discussed. Maximum present attainment for duralumin is represented by tests in Germany on a quenched and air-aged specimen which was further cold-rolled and then aged at about 125° C. The tensile strength was around 64,000 lbs./in.², the yield point 46,000 lbs./in.² with an elongation of over 20%. The Al alloys best adapted to casting or forging are also described together with a discussion of the application of the fabricated alloys to aircraft construction. CMB (9)

Safety of Buildings Constructed with Metallic Frame Work. (La sicurezza delle costruzioni edili con ossatura metallica.) P. Ameri. *La Metallurgia Italiana,* Vol. 24, Feb. 1932, pages 104-110.

General discussion of advantages of steel frame work buildings compared with reinforced concrete. The former are easier to calculate and to test, and even where fire and earthquakes are to be considered, they are preferable. The article is of a qualitative rather than a quantitative nature. Paper before the Wissenschaftliche Gesellschaft für Luftfahrt, May 1931; reviews the progress of Al and Be alloys and CrNi steels employed in aircraft construction with special reference to sea-planes. EF (9)

Use of Aluminum in Architecture and Decorating of Homes. (L'Aluminium dans L'Habitation). Henri d'Auriguy. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Aug. 1931, pages 404-414.

A general survey of chemical, physical and mechanical properties of Al alloys. Principal uses of Al alloys in decorating homes. GTM (9)

Metal Best for Walls of Buildings. M. B. Bowman (Bowman Bros., Inc.). *Iron Age,* Vol. 128, Dec. 24, 1931, page 1619.

The advantages of metal walls lie in the great strength obtainable in the small thickness and the weathering qualities of such materials as Al, rustless steel and Cu. 6 all-metal buildings are slated for construction during 1932. VSP (9)

Aluminum and Its Alloys in Navy Construction. (L'Aluminium et ses Alliages dans les Construction Navales.) A. de Biran. *Revue de L'Aluminium,* Vol. 8, Mar.-Apr. 1931, pages 1371-1396.

Historical development and present status of the use of light metals and their different applications and possible savings reviewed; particularly in marine construction. (9)

Alloy Steels in Cracking Equipment. G. Egloff & J. C. Morrell. *Refiner & Natural Gasoline Manufacturer,* Vol. 10, Apr. 1931, pages 77-80.

Cr and Ni steels are chiefly used; others are important, notably those with Cu and Si; the most important parts in cracking equipment are: furnace tubes, headers and plugs, piping and pipe connections. Examples of corrosion are illustrated. WHB (9)

Valves and Valve Steels and Their Heat Treatment. Part II. E. F. Davis. *Fuels & Furnaces,* Vol. 9, Nov. 1931, pages 1259-1264.

Automobile valves are made by forging or extrusion at 1800°-2100° F., or by welding stem to head. The alloy steels used contain Cr from 1.8 to 18%, Si 0.4-4.5%, Ni not over 2.5%, Cu 4-9.5% or Al 1.75-6%. W, V or Mo steels are rarely used in America. Selection of alloy depends largely on whether the valves are to operate below 1000° or at 1400°, 1500° or 1600° F. After forming the valves are annealed at 1400°-1650° F. to improve machinability but further heat treatment is confined to hardening of the stem tips only to give a hardness of C22 to C28 Rockwell. Qualities demanded in the valves are resistance to corrosion, strength, forgeability or weldability, and toughness. CMB (9)

Stainless Steel Car Weighs Less than Seven Tons. *Railway Mechanical Engineer,* Vol. 106, Apr. 1932, pages 137-141.

Detailed construction data of a Diesel electric car of the French Michelin Co. is given; the entire frame of the car is built up of cold pressed and spot welded sections of 18% Cr, 8% Ni stainless steel. The wheels have inflated pneumatic tires at 85 lbs. pressure within the steel tires. The total weight of the car is 13,548 lbs. Ha (9)

Use of Stellite in the Mining Industry. R. A. Elliot. *Canadian Mining Journal,* Vol. 53, Feb. 1932, pages 70-71.

A brief reference to the successful applications and to the possibilities of saving in costs effected by the use of stellite in the industry. The application of stellite by means of the oxy-acetylene torch or the electric arc as hard facing metal is called stelliting and is quite similar to the application of Fe by welding. Successful applications include: clamping dies, shovels, pulverizing hammers, screw conveyors, roaster rabble blades and shafts. Means of application are briefly reviewed. WHB (9)

Cast-Iron Pipe for Columns and Column Cores. *Engineering News-Record,* Vol. 108, June 9, 1932, page 827.

Pipes tested were 4.2" inside diameter and 0.3" thick, with a sectional area of 4.3 in.² The lengths ranged from 42" to 105". The columns tested were: 1. Cast-iron pipe alone. 2. Pipe filled with concrete. 3. Hooped concrete with pipe core. 4. Hooped solid concrete, for comparison. Gravel concrete of of 1:1½; 2¼ mix was used with 6 gal. of water per bag of cement. The columns were 23 days old when tested. Plain cast-iron pipe columns gave ultimate loads ranging from 201,000 to 217,000 lb., concrete-filled pipe 266,500 lb., solid concrete columns 285,000 lbs., and for the cored columns the ultimate loads ranged from 338,000 to 400,000 lbs. CBJ (9)

Mass Production Economies Sought for Small-House Construction. *Engineering News-Record,* Vol. 108, June 2, 1932, page 800; *Brick & Clay Record,* Vol. 80, June 1932, pages 295-296.

American Institute of Steel Construction held small-house forum with discussions by engineers and architects. Steel is a good residence material not only for its strength characteristic but for its ease of fabrication and erection and its ability to serve as a skeleton on which to hang materials. A potential market of 3,600,000 tons annually is available (assuming 300,000 new 6-room houses per year) made up of 2,250,000 tons of shapes in the frame and 1,350,000 tons of sheet and strip in walls, floors, etc., according to the findings of a committee studying this problem. Majority of speakers favor shop fabrication and field assembly. CBJ (9)

Federal Conservatory Uses Aluminum-Alloy Framing. *Engineering News-Record,* Vol. 108, Apr. 14, 1932, pages 539-542.

Al trusses, purlins and glazing bars are used quite extensively in the new conservatory being built for the U. S. Botanic Garden at Washington, D. C. These were adopted mainly to reduce the cost of their maintenance, cleaning, and painting especially in the lofty portions that are difficult of access and are subject to hot moist atmospheric conditions favorable to corrosion. Purlins and ridge chambers were fabricated of 4 S rolled ⅛ H or ¼ H; other shapes, plates, rivets, and bolts, 17 ST; glazing members, 3 S ¼ H; and cast Al 43. CBJ (9)

Bearings for Heavy-Duty Service. *Iron Age,* Vol. 128, Dec. 24, 1931, pages 1633-1635.

Includes discussion. A symposium held in New York at the annual meeting of the American Society of Mechanical Engineers and sponsored by a special research committee on heavy-duty, anti-friction bearings. A brief abstract of 5 papers that were presented is given. VSP (9)

Long-Span Steel Framing in Pittsburgh Building. *Engineering News-Record,* Vol. 108, Apr. 7, 1932, pages 510-512.

New 37 story Gulf Oil building contains no columns in rentable space in the 30 story tower portion. Columns are grouped about elevator and service areas that form the core of the building. Double girders span between these columns and the wall columns. A special three-web built-up column was developed to carry the large column loads. CBJ (9)

Steel-Plate Floor of New Type Installed in Several Buildings. *Engineering News-Record,* Vol. 108, June 23, 1932, pages 889-890.

Floor unit is made of two preformed sheets. The cross section shows 4 keystone-shaped cells formed by a V-shaped bottom element and a U-shaped top element, welded together above the neutral axis. Most units used were 2' wide and 7' 7" long, although heavier units are made 12" wide. Span lengths also vary from 6 to 30'. The floor units to date have been made of pressed-steel sheets but a special rolling-mill is being built for future manufacture. The top and bottom elements are welded by resistance process. After welding each section is dipped in a hot asphalt material to protect against corrosion and serve as a binder and cushioning layer between the steel flooring and the concrete slab, or it receives a baked enamel finish as required by the underwriters, when the cells are utilized as electric conduits. Construction details are discussed. CBJ (9)

Large Uses of Steel in Small Ways. 208th Article. Wheelbarrows. *Steel,* Vol. 90, Jan. 11, 1932, page 30.

The wheelbarrow industry normally consumes 9000 to 10,000 tons of steel annually. In 1930 there were 341,000 wheelbarrows manufactured (all-steel, part-steel, and wood) with an attendant consumption of 8655 tons of steel. JN (9)

Welding on the U. S. Airship Akron. Irving B. Hexter. *Paper read before the 32nd Annual Convention, International Acetylene Association,* Chicago, Nov. 1931, 5 pages.

Data of the U. S. Akron are given and a brief description of where and how welding was applied in the construction. Ha (9)

New Welded Constructions in Steel Structures. (Neue geschweisste Konstruktionen im Stahlbau.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Jan. 31, 1932, pages 61-62.

The article gives a few examples of new types of welded steel constructions. GN (9)

Heat Radiators. (Les Echangeurs Thermiques.) *Revue de l'Aluminium,* Vol. 9, Jan.-Feb. 1932, pages 1643-1649.

Several types of radiators of Al and light metals are described. AH+Ha (9)

Light Metal in Ship Building. (Leichtmetall im Schiffbau.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Mar. 1932, page 155.

A general survey is given on the application of light metal in ship building. GN (9)

Manufacture of Tubes Provided with Ribs and Their Behavior under Thermal Stress. (Herstellung und Verhalten wärmebeanspruchter Flügelrohre.) *Die Röhrenindustrie,* Vol. 24, June 18, 1931, pages 145-147.

The manufacture of tubes with welded-on ribs and their utilization are reviewed. The theoretical factors dominating the temperature course and testing results from measurements up to the present time are communicated. The effects of thermal expansions are pointed out and equipments for measuring the temperature conditions are given. The advantages of employing tubes provided with ribs are summarized with special reference to the efficiency of combustion chambers. EF (9)

Hopper Cars are Built of Aluminum. *Railway Mechanical Engineer,* Vol. 106, Apr. 1932, pages 131, 134.

The detailed construction of 10 hopper cars of 70 ton capacity with bodies of Al alloys is described; the weight of each car is 38,900 lbs.; a saving of 21,200 lbs. was obtained. Ha (9)

Aluminum in the Dairy Industry. (Aluminium in der Milchindustrie). *Schweizerische Technische Zeitschrift,* Vol. 29, Apr. 21, 1932, pages 251-252.

The application in Switzerland of the Al-alloy Anticorodal to milk cans is described. Such cans are seamless pressed out of one piece and then improved by a special aging process. The advantages of Anticorodal for such purposes as contrasted with other materials are outlined. GN (9)

Hard-Facing High-Pressure Valves. *Power,* Vol. 75, Apr. 12, 1932, page 549.

Valves on the duplex boiler feed pumps of a southern company failed regularly after 500 hr. of operation. A thin stellite layer applied by oxyacetylene welding raised the life to 5000 hr. Failure was due to mushrooming of the base metal of the hard-faced disk seat. A harder and tougher base metal and a thicker deposit of the facing material increased their ratio over steel by more than 10 to 1. AHE (9)

Materials in Ships. W. E. Blewett, Jr. *Product Engineering,* Vol. 3, June 1932, pages 229-233.

Speed, capacity, freight-handling facilities and space requirements demand building materials of highest quality in ship building. The average physical properties and chemical composition of some high-elastic steels are tabulated, specifications for castings discussed and the importance of non-ferrous metals illustrated. Ha (9)

Arc-Welded Pipe Line for Gold Mining. R. F. Allen. *Industry & Welding,* Vol. 3, Mar. 1932, pages 2-4, 11.

The total length of the line is 5228' with 40" intake diameter tapering down to 9" at the monitors; the line is welded throughout its length and serves for alluvial gold mining in Columbia. Ha (9)

The Strength of Automobile Tube Frames. (Die Festigkeit von Automobilrahmen.) K. Adloff. *Die Röhrenindustrie,* Vol. 24, Apr. 9, 1931, pages 85-86; Apr. 23, 1931, pages 101-102; May 7, 1931, pages 113-114.

The advantages of a tube frame in comparison with the traditional profile iron frame is explained with the aid of the theory of strength of materials. The vibrations to which the tube frames and the chassis are exposed are outlined and the oscillation strength of the latter are discussed. EF (9)

Metals in the Pantograver. William E. Bailey. *Brass World,* Vol. 28, Apr. 1932, pages 70-71.

An illustrated description of the device used by the Navy Dept. for making engraved Cu plates for printing maps. The pantograver is essentially an improved collapsible parallelogram operating on the pantograph principle. WHB (9)

Architectural Art-Craft and Fusion Welding. (Architekturwerkkunst und die Autogenschweissung.) Jos. Bluemmel. *Die Schmelzschweissung,* Vol. 11, Apr. 1932, pages 75-77.

The possibilities of welding in architectural ornamenting are illustrated by some designs of doors, lattice work, etc. Ha (9)

Tubes in Automobile Construction. (Das Rohr im Automobil.) K. Adloff. *Die Röhrenindustrie,* Vol. 24, Mar. 26, 1931, pages 76-77.

With reference to the recent Automobile Exhibition, Berlin, a new trend in automobile design was noticed insofar as an increasing number of companies incorporated tubes in their models. The salient features involved in the calculation of the frame are reviewed. In favor of the tube frame, the favorable resistance moment of the circumferential cross-section is pointed out and the different frames on the Exhibition are briefly characterized. The writer's remarks on the steels and welding performances are of general nature. The replacement of the front axis by tubes have been carried out by some manufacturers. The further use of tubular parts in automobile bodies is summarized. EF (9)

HEAT TREATMENT (10)

Working and Heat-Treating Steel. (Lavorazione e tempera degli acciai.) A. Massenz. Ulrico Hoepli, Milan, 1931, 5th edition. Cloth, 4¼ x 6 inches, 252 pages. Price 12 lire.

This is a pocket-size shop manual of an elementary nature, chiefly dealing with practical shop methods. Emphasis is laid on methods of quenching small tools to prevent cracking. Very little is said as to working, the volume dealing chiefly with heat-treatment, and including brief comment on carburizing, spark testing, hardness testing, pyrometry, etc.

It is stated that steel is not heat-treatable with less than 0.45% C, so the metallurgy contained has to be taken with a grain of salt. There is no alphabetical index.

H. W. Gillett (10)-B-

Recent Progress in Rail Material. (Les derniers Progres en Matiere de Rails.) Edmond Marcotte. *Revue Générale des Sciences*, Vol. 43, Feb. 15, 1932, pages 81-86.

In reviewing the various means applied for an improvement of rails the heat treatment with a view to obtain a sorbitic structure has proved to be very valuable as it results in a greater economy in the replacing of rails. The sorbite treatment is effected by passing the rail through the furnace in a certain temperature zone. Shoes and bonds should be treated in the same way. Ha (10)

Recent Progress in Heat Treatment of Ball-Bearing Races. Haakon Styri. *Metals & Alloys*, Vol. 3, Feb. 1932, pages 38-39.

The author describes equipment developed for the treatment of ball-bearing races which has resulted in greater elimination of the human element and a more uniform product with improved conditions of working. WLC (10)

Safety of Personnel an Important Factor in Heat Treating. Norman Kyser & R. H. Ferguson. *Steel*, Vol. 90, Jan. 25, 1932, pages 23-25.

A detailed abstract and résumé of a pamphlet on "Safe Practices in Heat Treating," issued by the National Safety Council. The pamphlet discusses the hazards presented to workmen engaged in the various phases of heat treating operations in metal working plants and recommends the safety precautions to be observed in each case. JN (10)

Hardening (10a)

Speculation on Hardening by Electromagnet. Correspondence from W. Rosenhain. *Metal Progress*, Vol. 21, Mar. 1932, pages 71-72.

Calls attention to discrepancies in the research of E. G. Herbert on the electromagnetic hardening of steel.

WLC (10a)

Choice and Hardening of High Speed Tool Steel. (Auswahl und Härtung von Schnellstahl.) W. Schoening. *Maschinenbau*, Vol. 11, Jan. 7, 1932, Pages 12-14.

Compares American and German practice of hardening high speed tool steel. The former takes place at lower temperatures, thus avoiding any decarburization of the surface. Some experiments are reported revealing the strong influence of the quenching and subsequent drawing temperatures and the time of heating on hardness, toughness and surface. Toughness decreases rapidly with higher temperature whereas sufficient hardness with greater toughness will be obtained by longer soaking and lower quenching temperature. Tools soaked for one minute at 1230° C. gave better results than those quenched from 1290° C. without any soaking. For the regular high Cr and W tools the former practice proved best by securing 64 Rockwell C with little decarburization and satisfactory tenacity. It should be preferred to the Rockwell 66 C of the latter method. For proper drawing a temperature of 565°-580° C. is recommended with a 30 minutes' soaking and cooling in furnace or in the open air. Some practical hints are given as to prevention of cracking and distortion. RFV (10a)

Annealing (10b)

Annealing of High Grade Sheet Metal. (Die Glühung von Qualitätsfeinblechen). E. Marke. *Stahl und Eisen*, Vol. 52, Mar. 17, 1932, pages 262-266.

Annealing in open fire, pot, continuous and normalizing furnaces all given in detail as to temperature, furnace size and construction, fuel used, cooling, etc. Distinction is made between ordinary and "normal" annealing; in latter method temperature is brought appreciably above Ac_3 point, followed by period of rapid cooling, and finally slow cooling. Disadvantages of continuous furnace annealing compared with annealing in single or double pot furnace are: 1. Hot gases on both sides do not uniformly surround pots. Carriage and lower section of pot absorb great part of heat, and annealing in various parts of pot is not uniform. 2. Furnace cannot always be charged uniformly with same high grade material. 3. Slow cooling often produces large crystal grains, restricting physical properties, which is not desirable. Each pot, in a single pot furnace, undergoes its special heat treatment, with rather rapid cooling, permitting pot to be withdrawn from furnace while at red heat. Flame uniformly surrounds pot in pot furnace. Advantages of continuous furnace over pot furnace are: 1. Fewer pots used up. 2. Less fuel used. Advantages of "normal" annealing over all other methods are: 1. Finished sheet is exceptionally uniform in physical properties and structure, permitting highest deep drawing work. 2. Normalizing may be carried out conveniently and safely, even with larger sheets. 3. No pots needed. 4. No danger of sheets sticking, which is great in pot and continues furnace annealing. 5. More tonnage can be annealed in a few hours in normalizing furnace than can be annealed in several days in pots. Following classes of sheets should be normalized: 1. All sheets annealed only once, that must possess highest deep drawing qualities. 2. For specially clean surface sheets, in addition to having good deep drawing qualities, they should be normalized, pickled, cold rolled and pot annealed. 3. In many sheet mills for greatest security in obtaining sheets of high quality, "normal" annealing is used for final anneal. Structure of a normalized sheet is shown, containing 0.1% C, Erichsen 11.7 mm., Rockwell 54, T.S. 32.4 kg./mm², elongation 40.5% on 50 mm. length. DTR (10b)

Annealing of Copper Wire (Ricottura dei fili capillari di rame). O. Gamalfro. *La Metallurgia Italiana*, Vol. 24, Apr. 1932, pages 292-294.

The author claims that bright annealing of Cu wire can be accomplished by using a closed cast iron container, packed full of coils of wire so as to leave but a small air space. The oxygen of the air is alleged to be absorbed by the cast iron at 300° C. or above, 400° C. being the operating temperature. Laboratory tests on passing a measured volume of air over gray iron at 400° C. (composition of the iron and whether it was in turnings or in solid pieces not stated) are said to show the bulk of the oxygen to be used in oxidizing the iron, without formation of CO. The cast iron is oxidized as a whole. The presence of graphitic C is not harmful. Iron containers other than cast iron work all right on the first heat, but lose their ability to take up oxygen thereafter. Al acts in similar fashion. The porosity of cast iron avoids such a phenomenon in its use. No data are given on the life of the cast iron container. The statements made appear to be based primarily on laboratory tests, and do not carry conviction to the abstractor. In a closed container the residual oil on the wire is usually sufficient to produce a bright anneal if air is excluded during cooling so that the container may work all right without requiring the explanation as to preferential oxidation of cast iron. HWG (10b)

Case Hardening & Nitrogen Hardening (10c)

Recent Investigations of the Case Hardening of Locomotive Slide Bars (Neue Untersuchungen auf dem Gebiete der Einsatzhärtung von Lokomotiv-Gleitbahnen). Hellmut Cramer. Doctor's Thesis, Technische Hochschule, Hannover.

See *Metals & Alloys*, Vol. 2, Dec. 1931, page 309. (10c)

Development of Continuous Gas Carburizing. R. J. Cowan. *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1113-1117.

Paper read before the Iron & Steel Division of the American Institute of Mining & Metallurgical Engineers, Sept. 25, 1931. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 309. MS (10c)

The Present Position of the Nitriding of Metallurgical Products. (L'Etat actuel de la Nitruration.) L. Guillet. *Genie Civil*, Vol. 98, May 16, 1931, pages 489-495.

The developments of the subject are treated under the headings of (1) steels for nitriding, (2) the operation and control of the nitriding process and (3) the properties of nitrided steels and their applications. The very comprehensive test results are reproduced in diagrams and microphotographs, and the results of practical operations for various industries are tabulated. Ha (10c)

Quenching (10d)

Effect of Moisture in Salt Baths for Steel Treating. Bernard Thomas. *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1111-1112.

Irregular results obtained in quenching in newly made salt baths or those which had stood for a time without work indicated that moisture was the cause of the breakages. Although equal hardness could be obtained in two pieces of plate, one of which had been quenched in H_2O and the other in a salt bath, the former had needles of martensite which were much larger than those obtained in the latter. These large needles would tend to increase brittleness. Tests were then made by adding H_2O to salt baths known to be giving good results. Addition of only 1 part H_2O to a bath containing several cwt. of salt produced brittleness. The effects increased with addition of definite amounts of H_2O until a stage was reached where the results obtained were little better than those from an ordinary H_2O quench. The effects were felt up to a temperature of about 700° F. at which temperature the salt appeared to boil for about an hour. After this boiling, results obtained on quenching would again be satisfactory at any working temperature possible with the particular salt employed. This indicates that in order to be sure that a bath is free from moisture it should be heated to 700° F. and held there. MS (10d)

Sorbitization of Rails at Petrowsky Works. W. I. Malyi. *Domez.* (Achievements of Metallurgy in USSR and Abroad), No. 9, 1931, pages 34-60. (In Russian.)

Bessemer rails were quenched directly from the hot bed in water and were drawn by the heat still remaining in the metal. An automatic quenching jig received 12 m. rails, held them so as to prevent any distortion and immersed their heads in a water tank for about 30 sec. Full description of the quenching arrangement is given. Brinell, impact and tensile testing demonstrated that sorbitization of the head of the rail was quite uniform, though physical properties were somewhat spotty. On an average, impact values increased considerably while hardness and stiffness increased also. Altogether 82 rails were treated. (10d)

Drawing (10e)

On the Drawing Effects in Quenched Aluminum-Copper Alloys. (Ueber die Anlasswirkung von abgeschreckten Aluminium-Kupferlegierungen.) W. Stenzel. *Die Metallbörse*, Vol. 21, July 18, 1931, page 1350.

The paper before the Kaiser Wilhelm Gesellschaft für Metallforschung, 1931, mainly refers to investigations of von Goeler & Sachs, Hengstenberg & Wassermann, Dix & Richardson in addition to the speaker's own research work. The precipitation consists of four phenomena. The conversion of the homogeneous solid solution into a heterogeneous mixture takes place in 3 stages. EF (10e)

Aging (10f)

Properties of Locomotive Tires Change with Age. Correspondence from A. A. Stevenson (Ardmore, Pa.) *Metal Progress*, Vol. 20, Dec. 1931, pages 81-82.

The writer reports variations noted at the Standard Steel Works in 1898 in tensile tests on locomotive tires that can be explained as due to an aging effect. Data is given showing differences due to waiting a few days or a few weeks after the tire was made before testing. WLC (10f)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

Arc-Welded Factory Building in Canada. *Engineer,* Vol. 152, Dec. 11, 1931, pages 617-618.

Illustrated article describing the erection of the new switchboard building of the Canadian General Electric Company at Peterborough, Ontario, the first all-welded building of any size in Canada. The lowest breaking stress obtained by welder working on this building was 12,250 lb. per linear inch for ⅜" by ⅜" fillets. In periodical field tests made on tension test pieces only, an average tensile strength of between 53,000 and 54,000 lb./in.^{2} was obtained. In several cases the break occurred in the parent metal rather than in the weld. LFM (11c)

Outstanding Welding Developments in 1931. Compiled by the Meetings and Papers Committee of the Welding Society. *Sheet Metal Industries,* Vol. 5, Feb. 1932, pages 723-724, 727-728.

Generalities on the growth of the welding field are set forth and new types of welding and cutting apparatus are discussed AWM (11c)

Outstanding Welding Developments in 1931. Compiled by the Meetings and Papers Committee of the American Welding Society *Journal American Welding Society,* Vol. 11, Jan. 1932, pages 5-9.

The outstanding feature in the development of welding in 1931 was the presentation of the Structural Steel Welding Committee Report epitomizing a 5 years' program of study and tests of various types of welded joints. Developments in the following fields are also cited: Structural Steel Welding and Cutting, Pressure Vessels and Boilers, Pipe Lines, Machinery Construction, Tanks, Automotive Industries, Hard Facing, Plumbing, Heating and Steam Fitting, Railroad Welding, Marine Welding, Gas Cutting, Welding and Cutting Apparatus and Welding Wire. TEJ (11c)

Largest Welded Steel Bridge. Technical Publicity Dept. of the Skoda Works, Pilzen. *Journal American Welding Society,* Vol. 11, Jan. 1932, pages 27-28.

The largest fully welded trestle bridge in the world has a span of 161 ft. 5 in., width 27 ft. 5 in., surface in plan 4413 ft.^{2}, weight 143 tons. The bridge was designed and constructed by the Skoda Works and it connects the north and south parts of the Skoda Works in Pizen, Czechoslovakia. The article includes a list of other all-welded structures. TEJ (11c)

Fundamental Research Problems on Welding. Compiled by the American Bureau of Welding. *Journal American Welding Society,* Vol. 11, Feb. 1932, pages 5-7.

A list of 50 fundamental research problems in welding which need investigation. The problems are divided into the following groups: (A) Investigations involving physical tests, (B) Involving considerable metallurgical experience, (C) Problems in physics, (D) Problems involving welding procedure, (E) Structural studies, (F) Problems involving chemistry, (G) Psychological. TEJ (11c)

Report of the Oxy-Acetylene Committee. *Paper presented at the Annual Convention, International Acetylene Association,* Chicago, Nov. 1931.

The progress made in the year 1931 in methods, equipment, and products, research, educational and promotional activities and some other uses of oxygen and acetylene are exhaustively reviewed. Ha (11c)

Welded Connections Pass Rigid Tests. *Gas Age-Record,* Vol. 68, Dec. 19, 1931, page 881.

Expansion joints and the welds of the electric welded 22" Panhandle-Eastern pipe line were given spring tests and 800 lb. pressure tests with satisfactory results. VVK (11c)

Carbon Arc Welding. A. Y. Stirrat. *Welding Journal,* Vol. 28, Dec. 1931, pages 378-380; Vol. 29, Jan. 1932, pages 14-15.

Paper read before the members of the North-Western Branch of the Institution of Welding Engineers, Nov. 1931. Part I. In this portion of his paper, the author gives detailed procedure for carbon arc welding. It is very important that welders are well trained. Graphitic carbons, ½" to ¾" in diameter are used, with currents ranging from 400 to over 1000 amperes. Arc lengths from 1½" to 3" are employed. Welds are made in the horizontal position and are well hammered. Strength of carbon arc welds is satisfactory but ductility is low. Difficulty is encountered in controlling the arc blow. The author believes that the use of carbon arc welding will gradually decrease. Part II. Following a quite complete historical outline of the development of the carbon arc welding process, the author discusses proper technique for good carbon arc welding. A long arc, kept in constant motion, is essential. TEJ (11c)

Non-Destructive Testing of Welds. *Canadian Engineer,* Vol. 62, Feb. 2, 1932, pages 17-18, 52.

Non-destructive tests for welds consist of hydrostatic, air pressure, reheating with a blowpipe, the stethoscope and the X-ray. These are briefly described. VVK (11c)

A New Type of Steel Floor. Joseph G. Shryock. *Journal American Welding Society,* Vol. 11, Feb. 1932, pages 11-12.

A report of loading tests on 3 full-size floor panels. Panels made of light weight stair channels interlocked. Different methods of attaching the members to each other were used in each case, namely—bolts, rivets and tack welds. With safe working loads, all three types of construction were entirely satisfactory, but under overloading, both uniform and concentrated, the welded panel was much stiffer than either the riveted or the bolted panels. TEJ (11c)

Some Details of Welding in Boilerworks' Practice. E. W. Thompson & A. Jeavons. *Welding Journal,* Vol. 28, Dec. 1931, pages 366-370, 383; Vol. 29, Jan. 1932, pages 6-10.

Paper read before members of the Institute of Welding Engineers at Birmingham, Nov. 1931. Includes discussion. The authors review the development of welding processes as used in the manufacture of pressure vessels. Details of the hydraulic roller water-gas welding process are given. The authors believe that one of the most important points in producing a satisfactory welded vessel is correct heat treatment. Much progress will have to be made in electric welding before it can be used safely for high pressure vessels. Experiments show that ⅜" to ⅝" electrode with currents from 450 to 1000 amperes will be used, depositing metal at probably 50 lbs./hr. Tests show that the single Vee joint is better than the double Vee. TEJ (11c)

Arc Welding Brings Strength and Economy to Residence Building. J. F. Lincoln. *Welding*, Vol. 3, Feb. 1932, pages 92-95.

A description of arc welded steel frame house of practical design, the type of construction of which it is predicted will eventually become universal. This construction has many advantages over the conventional wood framing, the cost being approximately the same. 12 illustrations show the design and method of construction. TEJ (11c)

Equation for the Calculation of the Operating Costs of an Arc-Welding Shop. (Une formule pour le calcul des frais d'exploitation d'un atelier de soudure a l'arc.) Paul Neumayer. (Société Siemens-France.) *Revue Générale de l'Electricité*, Vol. 31, Jan. 23, 1932, pages 127-131.

Develops an equation for calculation of operating costs. By means of this equation, author compares two systems; (1) direct-current converter set and bare electrodes, and (2) transformer and coated electrodes. Discusses the influence of the various factors in the equation on operating costs. Favors the use of the first system. MS (11c)

The Advance of Electric Arc Welding. Edward Dacre Lacy. *Metallurgia*, Vol. 5, Apr. 1932, pages 209-210.

Reports some recent English applications. JLG (11c)

Industrial Concerns in England Advocate Welding. E. Dacre Lacy. *Welding*, Vol. 3, Feb. 1932, pages 99-102.

The author, having recently visited a number of manufacturing concerns in various parts of England, tells how equipment for chemical, gas, cement and ship building industries are fabricated by welding. Illustrated. TEJ (11c)

Electric Welding (La soudure électrique). Part I, II. Mathieu. *L'Industrie Électrique*, Vol. 40, Nov. 25, 1931, pages 523-527; Dec. 10, 1931, pages 548-551.

Reprinted from *Bulletin de la Société Française des électriciens*, Series 5, Vol. 1, Aug. 1931, pages 810-845. These parts deal with power supply of single-phase, d.c., and 2-phase welding apparatus, various processes of electric welding and resistance welding machines. MS (11c)

On the Effectiveness of Electro-Welded Reinforcements of Railroad Bridges. (Über die Wirksamkeit ausgeführter Verstärkungen von Eisenbahnbrücken durch Elektroschweissung.) R. Bernhard. *Die Elektroschweissung*, Vol. 3, Jan. 1932, pages 1-10.

The paper reports the results of investigations on the electro-welded reinforcements of 3 railroad bridges of the German Federal Railroad System. The extensions measured in the welded seams confirm that the seams participate in any movement of the parts adjacent to the seam. Permanent stresses could not be observed in the seams. X-ray examinations show the seams to be perfectly sound. GN (11c)

Specifications for Welding Piping for High Temperature and High Pressure Steam Service. F. W. Martin. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 7 pages; *Journal American Welding Society*, Vol. 11, Feb. 1932, pages 24-27.

Steam pressures of 1200 lbs. to 1400 lbs. are in use in many power stations with temperatures of 750° F. to 850° F. The very highest type of welded work is necessary for steam pipe operating under these conditions. A specification for welding must first require that the welder is competent to make first class welds and that he is of a mental and moral character to be entrusted with work of great responsibility. Second, it must inform the workman as to what kind of work is required in such terms that there will be a minimum of misunderstanding and errors in interpretation; and third, it must provide for supervision and inspection to insure that the finished work is as called for in the specification and will fulfill the requirements desired. These requirements are discussed by the author. See also "Metallurgical Requirements for High Temperature Piping," *Metals & Alloys*, Vol. 2, Oct. 1931, page 232. Ha+TEJ (11c)

The Influence of Current in Arc-Welding Soft Steel. F. Lefring. *Journal American Welding Society*, Vol. 11, Feb. 1932, pages 7-8.

Description of extensive welding tests carried out with A.C. as well as D.C. with either polarity at various current intensities on different thicknesses of metal. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 41. TEJ (11c)

Welding Reinforcing for Concrete Pipe. Jos. C. Coyle. *Welder*, Vol. 3, Jan. 1932, pages 19-23.

Two water lines using 60" pipe are described; pipes are welded in the field from sheets cut to size; each 12 ft. section weighs 7 tons. Ha (11c)

Arc Welding in Mercantile Shipbuilding. Provisions of the German Lloyd regarding the Use of Electric Welding in Ships. (Lichtbogenschweissung im Handelsschiffbau; Bestimmungen des Germanischen Lloyd über die Anwendung der elektrischen Schweissung auf Schiffen.) G. Buchsbaum. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Sept. 26, 1931, pages 1229-1230.

A historical sketch of the development of arc-welding in shipbuilding and a discussion of the instructions issued for electric arc welding of vessels. Ha (11c)

Arc Welding Large Cast Iron Pots. Ernest Bauer. *Welding*, Vol. 3, Feb. 1932, pages 95-96.

The author tells how cracked cast iron pots, 10 ft. in height, 10 ft. inside diameter, having a wall thickness of 2" to 3", are being successfully repaired by metallic arc welding. See also *Metals & Alloys*, Vol. 3, Apr. 1932, page MA 99. TEJ (11c)

The Stress Distributions in Fusion Joints. E. G. Coker & R. Lavi. *Proceedings Institution of Mechanical Engineers*, Vol. 120, May 1931, pages 569-602.

Includes discussion. Rather theoretical discussion of stresses in the more elementary forms of welded joints. All joints so far as workmanship is concerned were assumed to be perfect. RHP (11c)

All-Welded Hospital Building Erected at Boston. Anthony S. Coombs. *Welding*, Vol. 3, Mar. 1932, pages 147-149.

The author describes the erection of the first shop and field welded municipal structure in Boston. Includes design details, inspection and qualification of welders. The building required 492 tons of steel. TEJ (11c)

Phases of Gas Welding. Glenn O. Carter. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 4 pages.

A diagram, or chart of nomenclature is laid out for the various methods of welding; gas welding, with oxy-acetylene being subdivided according to the nature of the flame, i.e. according to whether there is an excess of oxygen, a neutral flame, or an excess of acetylene. The different points are discussed. Ha (11c)

Welding Allegheny Metal. G. van Dyke. *Machinery*, Vol. 75, July 1931, pages 875-876.

See *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 72. Ha (11c)

Automatic Arc-Welding Applications. A. M. Candy. (Westinghouse Electric & Mfg. Co.) *Machinery*, Vol. 38, Dec. 1931, pages 270-272.

Presents methods of applying automatic welding to several operations, including, car wheels, well casing tanks, etc. Machines used are made by Westinghouse. RHP (11c)

When a Bridge Becomes Old. L. R. Canfield. *Journal American Welding Society*. Vol. 11, Feb. 1932, pages 29-30.

An interesting description of the reinforcement of floor and superstructure of a 31 year old bridge by use of arc welding. TEJ (11c)

Discussion of Paper on "Maximum Stress; its Influence on Cost and Service Life of a Structure" by Everett Chapman. *Journal American Welding Society*, Vol. 10, Dec. 1931, pages 19-22.

Discussion of Paper presented at Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 19-22. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 306. TEJ (11c)

Resistance Welding, What it is and What it does. M. L. Eckmann. *Industry & Welding*, Vol. 3, Feb. 1932, pages 15-20.

The author classifies resistance welding as (1) flash welding and butt welding, (2) spot welding and projection welding, (3) seam welding and line welding. The 3 classes are discussed and the method of their operation described. Ha (11c)

Procedure for Welding High Manganese Steel Frogs and Crossings. A. F. Davis (Lincoln Electric Co.) *Journal American Welding Society*, Vol. 10, Dec. 1931, pages 51-52.

Instructions for reclaiming worn frogs and crossings of 12% Mn steel. TEJ (11c)

Gas Welding in the Automotive Industries. R. E. Esch. *Industry & Welding*, Vol. 3, Feb. 1932, pages 22-27.

The application of oxy-acetylene welding for the different stages in automobile manufacture is described. Ha (11c)

Variations in Battledeck Floor Construction. A. F. Davis. *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 31-32.

The author describes procedure used in the construction of a welded battledeck flooring for a 100 ft. by 50 ft. three story building. A wood floor may be laid over the steel plate by the use of 2" by 4" wood sleepers which are fastened to the steel plate by means of a special threaded nail. The floor is then nailed to the sleepers. TEJ (11c)

Safety Feature in Oxygen Regulator Construction. Earl M. Eveleth (Bastian Blessing Co.). *Welding*, Vol. 3, Jan. 1932, pages 20-21.

Discussion of some of the potential hazards present in the regulation of high pressure oxygen and methods used by the regulator engineer in minimizing these hazards. TEJ (11c)

Production Gas Welding of Sheet Steel Cylinders. Earl Eveleth (Bastian-Blessing Co.). *Iron Age*, Vol. 128, Sept. 3, 1931, page 634.

Discusses the fabrication of a refrigerant liquid receiver. It is a 14-gage steel cylinder, 4" in diameter and 10" long, made from 2 cup-shaped halves, joined at the center girth seam by welding. Results, over a period of mos., show that actual production of finished welds averages 45 pieces an hr. with a gas consumption of 0.53 ft.^{3}, each, of oxygen and acetylene per piece. VSP (11c)

Reduction of Manual Processes in the Manufacture of Milk Transport Cans by Acetylene Welding. (Verminderung der Arbeitsgänge bei der Fabrikation von Milchtransportkannen durch Azetylenschweissung.) W. Greiner. *Autogene Metallbearbeitung*, Vol. 25, Feb. 1, 1932, pages 38-40.

Detailed description of the cutting of sheets and welding of parts. Ha (11c)

Welding Field Storage Tanks. Edw. E. Dillman. *Industry & Welding*, Vol. 3, Feb. 1932, pages 8-11.

Describes a lap joint and a butt-strap joint for storage tanks with automatic welding machines. See *Metals & Alloys*, Vol. 3, Apr. 1932, page MA 100. Ha (11c)

Control of Welded Seams by the magnetographic Method. (Controle des soudures par la methode magnetographic.) C. Franche. *l'Électricien*, Vol. 63, Feb. 15, 1932, pages 81-83.

There has always been difficulty in controlling the condition of a welded seam. The following method is a simple and effective test method to determine the condition of the weld. An electromagnet is placed across the seam and a piece of paper over the seam between the poles of the magnet. Iron filings are spread over the paper. The magnetic lines clearly indicate whether the seam is continuous or interrupted by flaws or contains irregularities of any kind. WR (11c)

Gas Welding Opportunities under the Revised A.S.M.E. Boiler Code. Chas. E. Gorton. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 5 pages, Mimeographed.

The work done by the Boiler Code Committee since 1911 is reviewed; the newest 1931 edition does not place any objection in the way of using fusion welding methods for pressure vessels as long as they fulfill the requirements as to quality of weld. Ha (11c)

A Large Welded Steel Tank. (Ein geschweisster Stahlgrossbehälter.) E. Gentilomo. *Montanistische Rundschau, Stahlbautechnik*, Vol. 23, Aug. 16, 1931, pages 65-68.

Arc welding was employed for the erection of a tank in sugar industry. The peculiar conditions of the erecting place, tests on seams of welded samples involving differently shaped seams and water pressure tests on the completed tank are described at length. EF (11c)

Building up Worn Shafts by Arc-Welding. H. E. HERMANN. *Machinery*, Vol. 38, Nov. 1931, page 204.

The shaft of a tire welding machine was built up by welding when it was impossible to shut down long enough to replace the shaft. Metal was welded on to a depth of 3/16". RHP (11c)

Oscillator Stabilizes A. C. Welding Arc. J. B. GIBB. *Electrical World*, Vol. 99, Feb. 27, 1932, page 405.

Addition of a high-frequency oscillation circuit in parallel with the secondary of a welding transformer eliminates most of the obstacles that have prevented a.c. welding from competing favorably with d.c. welding. It avoids the necessity of a high open-circuit voltage in the secondary of the welding transformer to re-establish the arc when it is interrupted. A compact portable a.c. welder is illustrated. WHB (11c)

A Self-Stabilizing D.C. Welding Generator. K. L. HANSEN. *Electrical Engineering*, Vol. 51, Feb. 1932, pages 108-111.

A new machine is briefly described and illustrated that requires no external reactor, but employs a special field winding to compensate for resistance fluctuations in the welding circuit. The machine is completely self-contained and self-excited. Shifting of brushes permits very fine adjustments of current. Features claimed for the machine are (1) the external reactor has been eliminated, (2) current impulses in the main circuit are reflected into the generator field to quicken magnetic flux changes, (3) the exciter has been eliminated without resorting to a 2-pole armature and four-pole field structure, (4) all regulating rheostats and switches have been eliminated without limiting the range or adjustment of welding currents, and (5) desirable arc characteristics are obtained over the whole range. WHB (11c)

Welding of Nickel and its Alloys. (Zur Frage der Schweissung von Nickel und seinen Legierungen.) HANS A. HORN & W. GELDBACH. *Schmelzschweissung*, Vol. 11, Jan. 1932, pages 5-11; Feb. 1932, pages 40-43.

It is shown under which conditions and by which means sound and technologically good welds with Ni and its alloys could be made. Pure Ni, Mn-Ni alloys, Cu-Ni alloys cast and rolled (70% Cu, 30% Ni), and "Nicorro," an alloy of 67% Ni, 33% Cu, and German silver were investigated. Fluxes, welding rods and gas and electric welding methods were tested with regard to quality of the weld. The microstructure of all welds was taken and the physical properties for each individual test are tabulated. For details the paper must be referred to. Ha (11c)

Discussion of Paper on "Automatic Gas Cutting" by R. F. HELMKAMP. *Journal American Welding Society*, Vol. 10, Dec. 1931, pages 11-12.

Discussion of Paper presented at Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 36-38. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 17. TEJ (11c)

Allegheny Metal in Dairy Equipment. L. W. HOSTETTLER. *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 25-26.

Extracts from an address presented at the National Dairy Exposition, Atlantic City, Oct. 22, 1931. The author gives detailed procedure for oxy-acetylene and arc welding of 18% Cr—8% Ni steels such as Allegheny Metal. Resistance welding of this material is also mentioned. Weld decay and carbide precipitation are discussed. TEJ (11c)

Fundamental Data Pertaining to Resistance Welding. G. A. HUGHES. *Welding*, Vol. 3, Feb. 1932, pages 84-87; Mar. 1932, pages 154-156.

The author describes the principles of various resistance welding processes and the important factors affecting the spot welding process. By some one of the resistance welding methods, nearly all metals and alloys can now be welded. Steel plates over ¾" thick have been spot welded. Current used was 100,000 amperes and pressure 40 tons. The pressure required varies with the thickness of the work, chemical properties of the material and current used. Power factor on single spot welding machines ranges from .35 to .50. Tests show that where several spot welders are connected to operate from a single transformer, its kwa. capacity should be about 66% of the total rated kwa. of the welders. Copper electrodes give the best results. Chemical analysis of weldmetal shows it to be practically the same as the unwelded low carbon steel. For ideal spot welding conditions, the plate should be very close to the following analysis: C 0.25% or less, Mn 0.40-0.80%, P .025% max., S .025% max., Si low as possible. Part II. The four variables to be considered in resistance welding are: (1) the voltage across the electrodes, which is usually between 4 and 14 volts, (2) electrical resistance at the joint, (3) pressure of the electrodes, (4) current. Tests on open hearth steel of less than .40% C content show that average strength of resistance welds is 93% of strength of parent metal. The author discusses design of butt welding machines, efficiency of resistance welders, strength of welds and the testing of a resistance welded bar joist. TEJ (11c)

Welding in Structural Steel Work. (Die Schweissung im Stahlbau.) A. HILPERT (Technische Hochschule Berlin). *Montanistische Rundschau*, Vol. 23, Nov. 16, 1931, pages 89-93.

The rapid progress in the adoption of welding in structural work during the last 1½ years is reviewed. The legal enactments during this period of time are briefly considered, the advantages in comparison with riveting are summarized and the scope of welding is clearly shown in 13 representative illustrations. Paper at the Deutsche Bauaustellung, Berlin, 1931. See also *Metals & Alloys*, Vol. 2, Dec. 1931, page 307. EF (11c)

The Application of the Oxy-Acetylene Process in the Production of Motor Cars. R. E. ESCH. *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 23-25; *Paper presented to the 32nd Annual Convention of the International Acetylene Association*, Chicago, Nov. 1931, 6 pages.

The oxy-acetylene welding process has a well established field in the automobile industry. The author describes various applications of this process in the manufacture of automobile bodies and other parts. In construction and maintenance work in connection with plant equipment, the oxy-acetylene process, both for welding and cutting, is almost indispensable. Ha + TEJ (11c)

Relief of Welding Strains by Annealing. CHARLES H. JENNINGS (Westinghouse Elec. & Mfg. Co.). *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 26-29; abstracted *American Machinist*, Vol. 75, Nov. 1931, page 766; discussed *Journal American Welding Society*, Vol. 10, Dec. 1931, pages 24-26.

Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. A "soaking time-stress curve" chart is included. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 310. RHP + TEJ (11c)

A Sign of Progressive Manufacturing. I. C. JONES. *Journal American Welding Society*, Vol. 11, Feb. 1932, page 27.

Description of fabrication of a large electrically illuminated sign which was fabricated from 20 gage sheet steel by means of the oxy-acetylene welding process. Advantages of this method of fabrication are discussed. TEJ (11c)

Permanence for Roofs. OWEN C. JONES (Linde Air Products Co.) *Journal American Welding Society*, Vol. 2, Dec. 1931, pages 50-51.

Various building projects are described to illustrate the adaptability of the welding blowpipe for Al roofing installations. TEJ (11c)

Shrinkage Strains in Butt Welded Joints. C. H. JENNINGS. *Welding*, Vol. 3, Feb. 1932, pages 119-122.

Rigid 1½" butt joints of the 60° double vee type were arc welded with 5/32" bare mild steel electrode. Six types of welding procedure, varying in the method of depositing the weld metal and the application of peening in certain cases, were investigated. By taking strain gage measurements on each specimen before and after welding, data were obtained on which the author based the following conclusions: (1) There is very little difference between the shrinkage strains as obtained by the cross weave procedure and the horizontal layer procedure. (2) Smaller shrinkage strains were obtained by the vertical layer procedure than by the cross weave, horizontal layer and vertical weave procedures. (3) The vertical weave procedure developed the greatest shrinkage strains. (4) The peened horizontal layer procedure developed smaller shrinkage strains than the cross weave, the horizontal layer, the vertical layer and the vertical weave procedures. (5) The peened vertical layer method produced the smallest shrinkage strains. (6) Peening is very effective as a means of reducing shrinkage strains in butt welds. (7) Stresses in butt welds are not evenly distributed along the joint. The exact stress distribution depends upon the rigidity of the joint and the method of welding. (8) Peening is very effective in producing a uniform stress distribution in butt welded joints. TEJ (11c)

Welding—The Engineer can Make it or Break it. R. KRAUS. *Product Engineering*, Vol. 3, Jan. 1932, pages 29-31; Feb. 1932, pages 77-78.

The success of welded designs depends greatly on the preparation, amount of welding, handling and accessibility of joints; these 3 factors are discussed from the point of view of using the metal to best advantage. Sketches show how welds should be arranged to avoid shrinkage stresses. It is the task of the designing engineer to take these points into account when laying out a welded piece. The correct and wrong way in using fillet welds is illustrated by examples in order to eliminate excessive welding and handling, increasing accessibility and speeding assembly. Ha (11c)

The Welding Engineer. (Der Schweissingenieur.) E. KALISCH. *Schmelzschweissung*, Vol. 11, Feb. 1932, pages 25-27.

The necessity of expert supervision of welding processes by properly educated or trained men is pointed out and the opportunities described which are offered in Germany for this purpose. The question is discussed whether this training should be simply directed towards producing an expert in welding or if also this curriculum of 13 weeks should give broader education in engineering; this is answered in the negative as these schools shall preferably train in practical ways. Ha (11c)

The New Keel Multi-Flame Blowpipe. C. F. KEEL. *Journal American Welding Society*, Vol. 11, Feb. 1932, pages 16-19.

Article from the Swiss *Journal de la Soudure*. Reprinted from the *Welding Journal*, Vol. 28, May, 1931. Author gives a description of an interesting and important innovation in oxy-acetylene welding, namely the so-called multi-flame blowpipe by the use of which it is claimed, the speed of welding can be increased 50 to 60% and the cost reduced 25 to 30%. The blowpipe and its operation are described and its various advantages over the single-flame blowpipe are discussed. TEJ (11c)

Discussion of Paper on "The Future of Welded Ship Construction" by J. KJEKSTAD. *Journal American Welding Society*, Vol. 10, Dec. 1931, pages 12-14.

Discussion of Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 13-16. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 310. TEJ (11c)

Stress Distribution in Welded Joints. (Die Spannungsverteilung in Schweissungen.) W. HOVGAARDT. *Zeitschrift für angewandte Mathematik und Mechanik*, Vol. 11, Oct. 1931, pages 341-348.

A mathematical treatment of (a) reinforcement and stiffeners and (b) lap welded joints. The formula derived by the writer is fully substantiated by previous experiments of Hammond Smith (*Journal American Welding Society*, Vol. 8, Sept. 1929) concerning lap-welded joints. EF (11c)

Riveting (11d)

An Investigation of Duralumin Rivets. I. G. SHOULGIN. *Central Aero-Hydrodynamical Institute*, No. 81, May 1931, 80 pages, 83 figures. (In Russian)

Several thousand mechanical tests of riveted joints indicate that for general work rivets of duralumin containing 2.5-3.5% Cu aged 7 days in air after quenching in water at 500° C. are the best. They have 21.5-23 kgs./mm.^{2} strength aged in driven condition and 24.5-26.3 kgs./mm.^{2} in undeformed state. Duralumin containing 2% Cu is too soft (20.5 kg./mm.^{2} and 22.5 kg./mm.^{2}) while the alloys containing 3.6-5% Cu are difficult to drive. They have 23.5-25.5 kgs./mm.^{2} and 26.5-28.5 kgs./mm.^{2} for tensile strength. Hand riveting promotes the formation of cracks in rivets. Time after quenching and the size of the clearance between the shank and the hole act similarly. Standard specifications for duralumin rivets used in Russia are given. (11d)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Refining of Bismuth. (Das Raffinieren von Wismuth.) THEWS. *Die Metallbörse,* Vol. 21, Sept. 12, 1931, pages 1705-1706.

The starting materials for the production of refined Bi are given and the removal of the following impurities are fully described: As, Cu, Pb, Zn, Te, Au, Ag. 10 references. EF (12a)

Melting of Grey and Malleable Iron in the Indirect-Arc Furnace. J. C. BENNETT & J. H. VOGEL. *Iron & Steel Industry,* Vol. 5, Oct. 1931, pages 19-21.

Condensed from a paper before the American Foundrymen's Association. Discusses results obtained, handling methods and costs. Higher costs are balanced by great flexibility of the furnace. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 312. CHL (12a)

The Scientific Principles of Open Hearth Steel Production. (Die wissenschaftlichen Grundlagen des Herdofenschmelzens der Stahlerzeugung.) E. LUBOJATZKY. *Montanistische Rundschau,* Vol. 24, Jan. 1, 1932, page 1-8; Jan. 16, 1932, pages 1-5; Feb. 1, 1932, pages 5-8.

The paper endeavors to systematically discuss the metallurgy of the open hearth process on the basis of our present knowledge. After establishing the saturation limit of FeO in Fe in dependence on the temperature, the law governing the distribution of FeO between slag and metal bath is investigated and the process of diffusion of FeO from the slag into the metal is explained by means of the osmotic pressure, the capillary attraction, Euler's continuity equation and considerations on the separation of admixtures which have been given by the author in previous publications in "Montanistische Rundschau." The relations of equilibrium for the oxidation of C, Mn, Si and P are reviewed. The theory of desulphurization which is based on Nernst's rule on the vapor pressure of oxides and sulphides is corroborated by practical experiments. The qualitative effect of Mn and Si on the deoxidation and the separation of the silicates formed is discussed. As to the quantitative possibilities of the deoxidation effects of these elements former investigations of the author are referred to. The physical laws favoring the formation of slag components which favorably affect the refining in the open hearth are summarized. Finally, it is pointed out that all occurrences in the open hearth must be correlated in order to successfully study the process. 45 references. GN(12a)

Casting & Solidification (12b)

Permanent Mould Foundry Practice for Bronze Castings. H. MARIUS. *Metal Industry,* London, Vol. 39, July 24, 1931, pages 75-76; July 31, 1931, pages 103-104.

See *Metals & Alloys,* Vol. 2, July 1931, page 135. (12b)

Rolling (12c)

Aluminium Sheet Production. Part XI. Planning Methods. Part XII. Rolling Operations. ROBERT J. ANDERSON. *Metallurgia,* Vol. 5, Jan. 1932, pages 87-90; Feb. 1932, pages 127-129; Mar. 1932, pages 161-163; Apr. 1932, pages 201-202, 208.

Gives methods for keeping records, scheduling and calculating amounts and sizes of slabs required for various sheet orders. Discusses rolling of slabs prior to finishing to gage. JLG (12c)

Slab Mill Driven by Three Reversing Motors. A. F. KENYON (Westinghouse Elec. & Mfg. Co.). *Blast Furnace & Steel Plant,* Vol. 19, Dec. 1931, pages 1560-1561, 1571.

Describes electric drive for a 44-in. reversing universal slabbing mill in the Chicago district. Ingots up to 30"x64" in cross section and weighing as much as 40,000 lbs. can be rolled. Main horizontal rolls are driven directly without pinions by a 10,000 h. p. twin motor drive consisting of 2 double armature, 5,000 h. p., 700 volt, 40-80 r.p.m., d.c. reversing motors. Combined maximum torque is 1970 ton-ft. corresponding to a peak capacity of 28,000 h. p. at 37 r.p.m. Vertical edging rolls are driven, through reduction and miter gearing, by a 2500 h. p., 700 volt, 79-225 r.p.m., single armature, d.c. reversing motor, with maximum emergency torque capacity of 250 ton-ft. at speeds up to about 74 r.p.m. Motors are connected in parallel and supplied with variable voltage d.c. power from a 5-unit, 6 bearing flywheel motor-generator set consisting of three 3500 kw., 700 volt, compound generators, connected in parallel, a 6500 h. p., 3-phase, 25 cycle, 6600 volt, 370 r.p.m. wound rotor induction motor, and a 90-ton, 15 ft. diameter steel plate flywheel, when running at synchronous speed of 375 r.p.m., rotating parts have a total stored energy of 270,000 h.p.-sec. Installation represents greatest power and torque applied to a reversing mill. MS (12c)

Forging (12d)

Production Control in Drop Forge Plants. L. E. RUBY (Pittsburgh Forgings Co.). *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1029-1033.

Discusses organization, operation and functions of a production control department. A unified production department and careful planning of every job greatly simplify operations and reduce costs. Forms used are illustrated. MS (12d)

Modern Drop and Die Hammers in Forging Practice. (Neuzeitliche Fall- und Gesenkhämmer in Gesenkschmieden.) S. WEIL. *Stahl und Eisen,* Vol. 52, Feb. 11, 1932, pages 144-148.

Improvements that have been carried out with drop hammers and swaging hammers in recent times are brought out in discussion and illustrations. Examples of the latest improvements are shown for lifting device, regulating device for a punch, stamp and die, rebound, drive for lift, plunger, flexible connection between the piston rod and the hammer plunger, etc. DTR (12d)

Behavior of Metals During Hot Pressing. (Verhalten der Metalle beim Warmpressverfahren.) *Die Metallbörse,* Vol. 21, Apr. 18, 1931, pages 724-725; May 16, 1931, pages 916-917; May 23, 1931, pages 964-965.

Summarizes the research work of Tammann, Tucker, Genders, Doernickel & Trockels, Pearson, Met and Smythe, with emphasis on the contributions of the last 3 investigators. EF (12d)

Machining (12g)

Cutting Steel with a New Cemented Carbide. ROGER D. PROSSER (Thomas Prosser & Son). *Machinery,* Vol. 38, Dec. 1931, pages 296-298.

Gives results of tests conducted on Widia-X to determine its capacity for machining steel. Permits increased speed and does not "crater" readily. Gives some suggestions for its use. RHP (12g)

Machinability of Free-cutting Brass Rod. ALAN MORRIS (Bridgeport Brass Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 454, 10 pages.

The "machineability" of free-cutting brass and a few other alloys was determined by means of a pendulum-type cutting machine in which the single tool swept out a section of the specimen and the energy used was measured by the swing of the pendulum. In the 60:40 brass a variation in the Cu content of several % had practically no effect on the machineability. As the Pb content of the brass increased the machineability increased rapidly up to 3 or 3.5% Pb. Heat treatment changed the machineability, and the machineability was apparently decreased by the β phase. Machineability was improved by cold work. Machineability could not be predicted from the tensile strength. 2 references. JLG (12g)

Machining Electro-deposited Nickel. C. H. FARIS. *American Machinist,* London, Vol. 74, Jan. 29, 1931, pages 68E-69E.

Tables are given for the grain size and hardness and velocity of grinding wheels and cutting velocities for turning and milling of electrolytically deposited Ni. Ha (12g)

Cutting Threads on a Rolling Gear Cutting Machine. (Gewindebearbeitung auf Räder-Wälzfrasmaschinen.) KURT GLASER. *Maschinenbau,* Vol. 10, Aug. 20, 1931, pages 532-534.

Various methods are discussed and the rules for choosing the correct method as well as the correct load are given. MAB (12g)

Drawing & Stamping (12h)

Reduction of Cost of Production of Steel Tube Connections by Combining Cold Drawing and Hot Pressing (Kostenverringernde Herstellung von stählernen Rohrverbindungen durch Kombination von Kaltziehen und Warmpressen). *Das Werkzeug (supplement to Maschinenkonstrukteur-Betriebstechnik).* Vol. 7, June 10, 1931, pages 127-128.

The crude material is prepared in a skillful way for hot-pressing by cold stamping and drawing. The method permits many variations and appears promising. MAB (12h)

The Production of Motor Laminations. R. L. PAYNE. *Metal Stampings,* Vol. 4, June 1931, pages 481-486.

There are three methods in common use for reducing Si steel sheets to strips for the production of motor laminations. A gang slitter cuts the sheet lengthwise into a number of unscalloped strips; a scroll shear cuts out scalloped strips along the width of the sheet; while a double crank press, equipped with either a 3-stage scalloping die or a 2-station progressive die, cuts the sheet lengthwise into scalloped strips. A fourth method uses a double crank press with a staggered gang die for blanking out plain lamination discs or wafers. JN (12h)

Thin Strip Steel for Deep Drawing. H. T. MORTON & I. A. RUMMLER (Hoover Steel Ball Co.). *American Society for Steel Treating Preprint* No. 21, 1931, 8 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The authors discuss tests for control of the quality of hot and cold rolled strip steel for deep drawing work. WLC (12h)

Pickling (12i)

Etching Aluminum Ware. (Das Beizen von Aluminiumstücken.) STEGER. *Zeitschrift für die gesamte Giessereipraxis; Das Metall,* Vol. 52, Jan. 11, 1931, page 12.

The compositions of solutions to give bright and matte finishes to Al articles and their methods of use are given. WHB (12i)

Influence of Pickling Operations on the Properties of Steel. H. SUTTON. *Rolling Mill Journal,* Vol. 5, Apr. 1931, pages 275-280, 290.

11 references. The pickling of iron and steel usually produces an effect of brittleness. The resultant changes in physical properties are attributed to the presence of absorbed hydrogen. The acid cleaning of low and medium-carbon steels is not detrimental and the brittleness produced is but temporary. In 10% H_2SO_4 solution, or in an equivalent solution of acid sodium sulphate, HCl, or HF, the degree of brittleness increases also with the temperature of pickling up to 122° F. This embrittling effect disappears gradually at room temperatures and more rapidly at higher temperatures. Bend tests and tensile tests made on laboratory test strips before and after pickling agree with these statements. A heat-treated Ni-Cr steel strip, however, displays very little brittleness after pickling. Electrolytic pickling in H_2SO_4 solution results in severe embrittlement, which disappears on heating to 212° F. Electrolytic pickling in caustic soda solution, sodium cyanide or a mixture of sodium carbonate and sodium bicarbonate produces but a slight embrittling effect. Cracks may develop during pickling in the case of steels that have been subjected to strain and insufficiently annealed. The addition of 2% pyridine or quinoline to an acid pickling bath may reduce the embrittling effect considerably. Hydrogen brittleness may be imparted to steel by the operations of electro-plating. This is a more permanent form of brittleness and requires more vigorous attention than does the brittleness resulting from acid pickling. JN (12i)

Cold Working (12j)

Mechanics of Chipless Forming; Rolling, Pressing, Drawing, etc. (Mechanik der spanlosen Formung; Walzen, Pressen, Ziehen, usw.). G. Sachs. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Jan. 16, 1932, pages 49-54.

The author points out that at the present time the flow phenomena of solid bodies, plasticity phenomena, still lack a mathematical treatment which would permit a practical prediction of behavior. The simplest question is that of the amount of energy required for a certain deformation; from this, the actual distribution of stresses should then be derived. The calculation and methods of taking of flow curves is discussed and diagrams are developed to show the behavior of and the distribution of stresses in a piece of metal after different kinds of mechanical treatment. The process of deep-drawing is also investigated, and calculated and tested curves for the press force against the path of the press plunger are given. 18 references. Ha (12j)

Methods used in Fabricating Allegheny Metal. *Machinery,* Vol. 38, Dec. 1931, pages 244-246.

Allegheny metal is an 18-8, Cr-Ni alloy having an ultimate tensile strength of 90,000 to 100,000 lbs./in.^{2} Elongation 60 to 70%. Little cold working will increase the tensile strength to 120,000 to 125,000 lbs./in.^{2} Discusses correct procedure in turning, cutting, drilling, punching, drawing, and pickling. RHP (12j)

Coldwork Method of Gun Construction. T. C. Dickson. *Army Ordnance,* Vol. 12, Nov.-Dec. 1931, pages 188-195.

The designer, maker and user of guns are not interested in "slip," "yield," "creep," "step," "slippage" and similar phenomena exhibited by the metal when in the form of solid cylindrical specimens, but they are interested in the maximum pressure to which a given gun can be subjected repeatedly with safety. Whatever may be the various phenomena produced in steel during coldworking, the practical fact remains, that single piece guns have been made by the coldworking process (enlargement of the diameter of the bore by coldworking from 1-12%) which, for the same dimensions and weight, are stronger than built-up guns. Experimental results show the maximum beneficial results are obtained by soaking hollow cylinders after enlargement of the diameter by coldworking at about 325° C. Centrifugally cast guns are normally coldworked to about 12% enlargement of the bore diameter, and soaked at 300° C. after coldworking. The advantageous results obtained on soaking hollow cylinders at low temperatures after coldworking are strongly emphasized. The soaking temperature should not exceed 325° C. This phenomenon does not apply to solid cylinders after coldwork as much as it does to hollow cylinders. This process of overstraining metals was developed primarily for making guns. It should, however, have useful applications industrially. The process should be carried out so the removal by machining of as little metal as possible from the bore is necessary. The Charpy impact value of the finished material after soaking is not less than 24 ft. lbs. if the safest results are desired. WAT (12j)

Improvements in the Cold Working of Metals. J. R. Miller. *Heat Treating & Forging,* Vol. 17, June 1931, pages 559-561.

Diffraction patterns show the different orientation of crystals for sheet rolled by driven rolls or drawn through rolls, both for annealed and for unannealed sheets. A diagram of a 4-roll mill for rolling strip metals under improved conditions of driven rolls is given. Ha (12j)

Preferred Orientation in Silver Foil Produced by Cold Rolling. Cleveland B. Hollabaugh & Wheeler P. Davy. *Journal of Rheology,* Vol. 2, July 1931, pages 284-291.

The mechanical working of silver foil by rolling produces 2 preferred orientations of crystals. Published work, heretofore, has given but a single position. The preferred orientation and the degree of preferment of each have both been found. See also *Metals & Alloys,* Vol. 2, Jan. 1931, page 12. WHB (12j)

Influence of Cold Working and Annealing on Brittleness of Copper. Clement Blazey. *Metal Stampings,* Vol. 4, Dec. 1931, pages 975-976, 986.

The factors causing brittleness in Cu cold worked and annealed are: annealing below a critical temperature, about 650° C., quenching from above the critical temperature; presence of As, P or Bi. The conditions are discussed in detail; it can be stated that Cu free from brittleness can be obtained when it is annealed above the critical temperature and quenched. Ha (12j)

Changes of Physical Properties by Cold Working and Formation of Solid Solutions and their Interpretation with Particular Reference to Tungsten. (Ueber die Zusammenhänge zwischen Kaltbearbeitung und Mischkristallbildung und ihre Deutung. Unter besonderer Berücksichtigung des Wolframs.) C. Agte & K. Becker. *Physikalische Zeitschrift,* Vol. 32, Jan. 15, 1931, pages 65-80.

The influence exerted by the solid solution on one hand and by cold working on the other hand on the physical properties is exhaustively treated with particular reference to W. The writers consider the effect of cold working on the tensile strength values, reduction of area, and the torsion modulus. Then the effect of heat treatment on the cold worked metal and the occurrence of elastic internal stresses due to deformations is dealt with. Furthermore the influence of additions resulting in the formation of solid solutions are considered with reference to the following systems: W-Ta, W-Mo and Zn-Cd single crystals. The effect of deformations by hammering and drawing on density and hardness are reviewed and the changes of electric properties due to (a) cold working and (b) formation of solid solutions is summed up. The statements selected from an extensive literature search are summarized with the object of disclosing analogies between the influence of cold working and the solid solution on both mechanical and electrical properties and the Mathiessen law is discussed. Furthermore the changes in (a) thermal, (b) optical and magnetic and (c) chemical properties by cold working and mixed crystal formation are covered in separate chapters. EF (12j)

DEFECTS (13)

Note on a Failure of a High Strength Brass. NEWSON & WRAGG. *Engineer,* Vol. 152, Sept. 1931, page 331.

Abstract of paper read before the Institute of Metals, Zurich, Switzerland, Sept. 1931. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 45. LFM (13)

Rail Failures in India. E. A. WRAIGHT & P. HINDE. *Iron & Coal Trades Review,* Vol. 122, June 19, 1931, page 982.

The majority of failures in the Indian rail service are due to defects in manufacture; they are described and special cases discussed. Heat-treated rails are not used. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 75. Ha (13)

Influence of Metallic and Non-Metallic Inclusions Upon the Properties of Bronzes. (Einfluss der metallischen und nichtmetallischen Verunreinigungen auf die Bronzen.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Feb. 7, 1932, page 67.

The effect of Sb, Pb, As, Fe, S, O and gases on the mechanical properties of bronzes is discussed. As is not so dangerous as generally assumed. GN (13)

Boiler Failures and Their Causes. *Engineering,* Vol. 132, Aug. 21, 1931, pages 241-243.

Summary of reports presented at the annual meeting of the German Association of Boiler Owners held recently at Dresden. LFM (13)

CHEMICAL ANALYSIS (14)

The Determination of Sulphur in Alloy Steels (Die Bestimmung des Schwefels in legierten Stählen). C. HOLTHAUS. *Archiv für Eisenhüttenwesen,* Vol. 5, Aug. 1931, pages 95-100.

Report 83 of the Chemist' Committee of the Verein deutscher Eisenhüttenleute. Report of the Sub-committee on the analysis of special steels. Includes discussion. The investigation critically examined the various methods of determining S in alloy steels. The methods tested were the following: the ether method: the combustion in O and the iodometric method according to Reinhardt. These methods were used to determine the S content of the following steels: a 2% and an 18% W steel, a 2% and a 9% Cr steel, a 0.3% and a 3% Mo steel, a 0.5% and a 2.2% V steel, a 5% and a 25% Ni steel, a 3% and a 10% Co steel, a 0.3% Cu steel, a 1% Al steel, a 12% Mn steel, and a 1% Ti steel. Some of these steels are taken from the normal production some of them were especially made in a coreless induction furnace by adding FeS. The results are as follows: (1) The ether method gives results of great accuracy with all the above steels. (2) Practically the same reliable results are obtained with the combustion method.

In comparison with the ether method, the combustion method offers the advantage of an essentially quicker performance. (3) The method (still in use in many laboratories) of determining the S content in alloy steels by dissolving the steel in hydrochloric acid gives reliable results only with low Ni steels, Co steels, Cu steels, Al steels and Mn steels. This method is no more reliable for V steels and entirely unfit for steels containing W, Cr, Mo, Ti and a higher percentage of Ni. In steels of such a composition it is necessary to determine the S content of the residue remaining after the solution in HCl. Due to this procedure, the iodometric method becomes most complicated and easily leads to incorrect values because of the many sources of error involved. The investigation arrives at the conclusion that S in alloy steel is most suitably determined by either the ether method or the combustion method. GN (14)

The Use of Zinc Oxide in Determinations of Cobalt and Manganese. JAMES I. HOFFMAN. *Bureau of Standards Journal of Research,* Vol. 7, Nov. 1931, pages 883-892.

If a precipitation by zinc oxide is made in a solution of a steel obtained by dissolving the steel in HCl or H_2SO_4 and oxidizing with HNO_3, the precipitate will contain all of the Fe, W, Va, Cr, U, Zr, Ti, Al, P, As, Sn, and nearly all of the Cu, Mo and Si. Ferrous Fe, W, if not previously oxidized, and small quantities of Si, Cu, Mo, Sb, Pb may be expected in the filtrate if these were present in appreciable amounts. Small amounts of sodium carbonate in the zinc oxide used in separating Co and Mn from Fe, Cr, etc., are not objectionable if only a slight excess of reagent is added. Separations of Fe and certain other constituents of steel from Co and Mn by precipitating with zinc oxide are satisfactory if double precipitations are made. Results for Co tend to be low if only a single precipitation is made. Neither single nor double precipitations are entirely satisfactory for the separation of large amounts of Ni. The temperature at which precipitations by zinc oxide are made has very little influence on the results. WAT (14)

Iodometric Determination of Small Quantities of Tin. (Ueber die jodometrische Bestimmung kleiner Menger Zinn.) ROB. HOELTJE. *Zeitschrift anorganische und allgemeine Chemie,* Vol. 198, June 10, 1931, pages 287-296.

The purpose of this investigation was to find how exactly Sn in amounts of one mg. and less can still be determined by the usual analytical methods; a modification of such method is described. Bi-valent Sn can be determined by titration with iodine solution and re-titration with thiosulphate. Quarta-valent Sn must first be reduced, most suitably by powdered Fe. In both cases the Sn, in amounts of 1 mg. and less, can be determined with an accuracy of about 5 g. Ha (14)

Rapid Determination of Chromium in Chrome and Chrome Nickel Steel. (Chromschnellbestimmung in Chrom-Chromnickelstahl.) W. HILD. *Chemiker Zeitung,* Vol. 55, Nov. 21, 1931, page 895.

A 2 g. sample is dissolved in 10 cc. HNO_3 sp. gr. 1.20, 20 cc. 1:1 H_2SO_4 and 150 cc. hot H_2O. 20 cc. $KMnO_4$ solution (8 g./liter) is added and the solution boiled for 4 min. The excess MnO_2 is reduced with 8 to 10 cc. $MnSO_4$ solution (100 g./liter). The solution is boiled, filtered through double paper, refiltering the first portion, and washed with hot water. After cooling, the solution is titrated in the usual manner. Accurate results can be obtained in 13 to 15 min. CEM (14)

Critical Investigation of the Reliability of the Vacuum Fusion Method for Determination of Oxygen in Steel (Kritisk undersökning över vakuumextraktionsmetodens användbarhet för bestämning av syre i järn och stal). G. ERICSON & C. BENEDICKS. *Jernkontorets Annaler,* Vol. 114, Nov. 1931, pages 549-589.

The vacuum fusion method was subjected to a detailed investigation and found to give a 100% yield of oxygen provided a uniform temperature is maintained on the graphite crucible, and loss of sample by spattering or volatilization is guarded against by a filter of glowing graphite particles. Cr, Mo, Ti, V and W do not affect the determination, but low results are obtained with an Al content of more than 2%. Mn introduces an error by volatilizing and depositing on the sides of the quartz furnace where it reabsorbs some O_2. HCD (14)

Determination of Oxygen in Steel by Hot Extraction. (Beitrag zur Sauerstoffbestimmung im stahl durch Heissextraktion.) P. BARDENHEUER & J. SCHNEIDER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, report 189, 1931, pages 215-221; *Stahl und Eisen,* Vol. 51, Dec. 17, 1931, page 1575.

The experiments were carried out in the apparatus as described by G. Thanheiser & C. A. Müller, *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 11, 1929, pages 87-94, which was improved in some details in order to obtain reliable results at temperatures up to 1600° C. The method was then tested on a large group of melts. The results show that Mn contents up to 1% do not disadvantageously affect the result of the oxygen determination. In Si bearing steels the reduction of the silica present offers no difficulties at sufficient high temperatures. Also alumina is completely reduced. The results were checked by the residue-chlorination method and found to be in accordance with this method. However, reliable results are obtained only when the evaporization of larger amounts of Al is avoided. Summarizing it can be stated that the hot extraction method for the determination of oxygen gives reliable results in investigating the total oxygen content of the largest number of the technical steels. 7 references. GN(14)

Technical Methods of Chemical Analysis. (Chemische-technische Untersuchungsmethoden.) BERL-LUNGE. Vol. II, Parts 1 and 2, 8th edition. Julius Springer, Berlin, 1932. Part 1, Cloth, 6½ x 9½ inches, 878 pages; Part 2, Cloth, same size, 917 pages. Price, Part 1, 69RM; Part 2, 69 RM.

Lunge's "Technical Methods of Chemical Analysis" needs no introduction to American chemists. The eighth edition issued under the name of Berl-Lunge will include 5 volumes, the first of which appeared in 1931. The second volume is issued in 2 parts. Part I includes the table of contents, and part II the author and subject index.

The arrangement of material is much the same as in earlier editions. The various sections have been written by experts in their respective lines. The first 454 pages of part I are devoted to the analysis of solid, liquid, and gaseous fuels; boiler, drinking, and waste water; and air. The remainder is devoted to the manufacture of the following products and the analyses involved therein: Sulphur dioxide; nitric, sulphuric, hydrochloric, and hydrofluoric acids; soda; chlorine; compressed and liquid gases; potash salts, and bromine. When the subject matter concerns a given industry the usual procedure is to discuss first the raw materials, then the intermediate products and plant-control methods of analysis, and finally the methods of analysis of the finished products.

Part II contains a short chapter on sampling of ores, metals, etc., and also a short section on the balance. Eighty-four pages are devoted to electro-analytical methods. This section consists of a short introduction followed by electro-analytical methods for silver, gold, bismuth, cadmium, cobalt, copper, mercury, nickel, lead, palladium, platinum, rhodium, antimony, tin, and zinc. Methods of separation from other elements are given.

The remaining 746 pages of part II are devoted to methods of analysis for the following elements: Silver, aluminum, arsenic, gold, beryllium, bismuth, calcium, cadmium, cobalt, chromium, copper, iron, hafnium, mercury, iridium, magnesium, manganese, molybdenum, niobium, nickel, osmium, lead, palladium, platinum, rhodium, ruthenium, antimony, silicon, tin, tantalum, thorium, and the rare earths, titanium, uranium, vanadium, tungsten, zinc, and zirconium. One hundred and forty-four pages are devoted to iron. Each element is treated in much the same manner. In a short introduction, the occurrence, minerals, manufacture, use, and importance are briefly described. General methods of determination are then described, and these are followed by methods of separation from other elements. Detailed methods of analysis of ores, various metallurgical products, metals, alloys, salts, etc., are then given. Analytical methods for various impurities present in the products are included. Usually several methods of analysis are described, and gravimetric, volumetric, and colorimetric methods are included when available. In many instances short methods are also described. At the end of many chapters typical analyses of ores, metals, alloys, etc., are given. It is regrettable that the chapter on iron does not include methods for determining non-metallic inclusions.

References are profuse in both parts. The eighth is a fitting successor to earlier editions. Both parts are excellent additions to the library of a research laboratory. Since part II covers in an excellent manner the analysis of a large number of metals and their products, it is especially recommended for chemical and metallurgical laboratories that might be prevented, owing to the high cost, from buying the entire volume. John D. Sullivan (14)-B-

Steel Plant Chemistry (Beiträge zur Eisenhüttenchemie. April-June 1931). A. STADELER. *Stahl und Eisen,* Vol. 51, Nov. 19, 1931, pages 1439-1441.

Eight publications are reviewed on (1) equipment, (2) analysis of pig iron, steel, ores, slags, additions, refractories, etc., and (3) fuels, gases, oils, etc. GN (14)

ECONOMIC (16)

South Africa in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 20.
Au output in South Africa increased by 154,386 ozs. to 10,874,146 ozs. AHE (16)

Manganese. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 12.
General economic conditions in 1931 are discussed. AHE (16)

Nigeria in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 21.
Nigeria produced 15,335 tons of 70% Sn ore in 1929, 11,902 tons in 1930 and about 10,500 tons in 1931. AHE (16)

Spain in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 48.
Apart from Fe and Cu, Spanish mine production was fairly normal in 1931. Figures are given. AHE (16)

Chromium. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 12.
The British Empire yields 2/3 of the world production of Cr from southern Rhodesia, the Transvaal, and British India. Output for 1931 is greatly below the 1930 figures (600,000 tons). AHE (16)

Cornwall and Devon in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 24.
The mining industry in Cornwall and Devon was at a standstill in 1931. AHE (16)

Norway in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 23.
Exports for 1931 were about ½ those of 1930. Pyrite production was about 365,000 tons, Fe about 570,000 tons, Ag 9½ tons, Ni 75,000 tons, and Mo concentrates 182,000 kg. AHE (16)

New Zealand in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 22.
Au production in 1931 increased over 1930. AHE (16)

Australia in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 22.
Au production for the 1st 6 months of 1931 was 258,359 ozs. (218,009 ozs. for 6 months of 1930). AHE (16)

Portugal in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 21.
As, Sn, Cu, W and Pb are mined in Portugal. Sn was the only one produced in quantity in 1931. AHE (16)

Eastern Canada in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, pages 17-18.
In 1931, Ontario produced Au $42,000,000, Ni $16,000,000, Cu $10,000,000, Pb $2,500,000, Ag $2,000,000 and Co $650,000. Total output was similar to 1928. Details are discussed. Quebec produced some $6,000,000 worth of metals. AHE (16)

Statistics on Swedish Production, Import and Export of Iron Ore, Iron and Steel. (Uppgifter över Sveriges tillverkning, in- och utförsel av Järnmalm, Järn och Stal.) *Jernkontorets Annaler,* Vol. 114, Sept. 1931, pages 487-492.
Export ore dropped to 2,173,000 T. for the first 6 months of 1931 from 5,026,000 T. for the corresponding period of 1930. Iron and steel exports are down to the lowest level reached in the last decade 80,900 T., the greatest being 131,700 T. in 1927. Imports are down to 180,000 T. as against 225,800 T. for 1930 and 170,300 for 1929. No tendency towards improvement is visible. HCD (16)

Iron and Steel in Manchuria. *Foundry Trade Journal,* Vol. 46, Feb. 11, 1932, page 104.
A brief statement of the iron and steel situation in Manchuria and the manner in which it affects the pig-iron situation in Japan. OWE (16)

The Gold Supply Increases. S. D. Strauss. *Engineering & Mining Journal,* Vol. 132, Apr. 1932, pages 210-214.
Gold production continues to increase. In a world of stagnant trade it is probably the most important factor now making for economic recovery. WHB (16)

Chromite in 1930. Lewis A. Smith. *Mineral Resources of the United States,* 1930, United States Bureau of Mines, part 1, Dec. 21, 1931, pages 243-266.
World production of chromite in 1930 decreased about 18% to 492,000 long tons. The U. S. imported 327,000 long tons, an increase of nearly 3%. In the U. S. 310 long tons were mined, all in Calif. (543 tons in 1929). Increased use of high-Cr alloys held up the consumption somewhat. Production of chromic acid for Cr plating increased. (Includes 100 references). AHE (16)

Nickel in 1931. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 11.
Ontario production of Ni in 1931 declined 36% to 66,103,521 lbs. The main development of the year was the use of Ni-clad steel for tanks and for tank cars for caustic. Ferro-Ni alloys containing 20-30% Ni and 2% Cr is being adopted for fittings in caustic plants and paper mills. Melting and cyanide pots of Ni 14, Cu 6 and Cr 2% are finding use. Other new uses are described. AHE (16)

A Review of Recent Discussion Regarding Gold Money. Scott Turner (U. S. Bureau of Mines). *Mining Congress Journal,* Vol. 17, Dec. 1931, pages 662-664, 670.
Includes world's production of gold and silver, 1876-1930 inclusive, in millions of ounces. DTR (16)

The Rehabilitation of Silver. Marshall W. Tuthill. *Mining & Metallurgical Society of America, Bulletin* No. 223, Vol. 25, Jan. 1932, pages 13-19.
A plan submitted by the Sub-Committee of the International Chamber of Commerce in Washington to seek a solution of the consequences of the present Ag situation with reference to the economic condition of the world is discussed. Bimetallism would very likely become universal but whatever plan is adopted it must be based on a concerted action of all nations concerned. Ha (16)

Magnesium and Its Compounds in 1930. Paul M. Tyler. *Mineral Resources of the United States,* 1930, *United States Bureau of Mines,* Part 1, Dec. 1931, pages 181-203.
The output of new ingot Mg in 1930, 1,173,557 lbs., was more than double the output in 1928 and only 12% less than in 1929. Prices fell from $1.00 to $0.48 per lb. in 100 lb. lots. Improvements in technology are reviewed. AHE (16)

The Coming Rise in the Value of Silver. A. J. Wright (A. J. Wright & Co.). *American Metal Market,* Vol. 39, Jan. 8, 1932, pages 3-4.
Prediction that the value of silver will rise from now on. DTR (16)

Iron and Steel in 1931. J. H. Thompson. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 10.
Pig Fe production in 1931 was about 56 million tons, crude steel, 70 million, a decline of about 40% from 1929. AHE (16)

Consumption of Primary Tin in the United States During 1930. John B. Umhau. *Information Circular* 6564, *United States Bureau of Mines,* Jan. 1932, 7 pages.
In 1930, 65,448 long tons of primary Sn were consumed, a 12% decrease from 1928. This is 38% of the world's Sn production. All uses showed substantial decreases except Sn plate, terneplate, white metal and tinning which showed small increases (1,200 tons). The largest tonnage decrease was in babbitt (33%). Consumption by uses is discussed. AHE (16)

Gold in 1931. E. Baliol Scott. *Mining Journal,* Annual Review No., Feb. 13, 1932, pages 1-2.
With the exception of Southern Rhodesia every country increased Au production in 1931. Total increase was over 936,000 ozs. AHE (16)

Tin in 1931. E. Baliol Scott. *Mining Journal,* Annual Review No., Feb. 13, 1932, pages 5, 7-8.
Production, consumption and price of Sn declined in 1931. Estimated production was 144,343 tons, a decrease of 27,858 tons. Cartels and trade agreements are discussed. AHE (16)

Lead and Zinc in 1931. O. W. Roskill. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 9.
Pb and Zn suffered in the general decline of 1931. Cartels are discussed. AHE (16)

The Mineral Industry during 1930. Vol. 39. Edited by G. A. Roush. McGraw-Hill Book Company, New York, 1931. Cloth, 6½x9½ inches, 815 pages. Price $12.00.
So far as is possible, this volume covers the developments of the year in each individual field, including production and trade statistics, technical progress, extensions of plants, new sources and uses, market conditions and prices and other items of interest, both domestic and foreign, each subject being placed in the hands of a specialist. In the list of contributors one new name is included, that of George S. Herrick, who has taken over the iron and steel section. Frank L. Hess, after one year's absence, again has taken up the section on radium, uranium, and vanadium.
As one further step in the consolidation of related subjects, the former separate section on borax has been incorporated in the chapter on sodium salts. In addition to the regular sections found in past volumes, an interesting and valuable graphical record of metal prices over a long period of years has been included. (16)-B-

The Possibilities and Prospects for the Utilization of Canadian-Produced Copper in Home Manufacturing Industries. A. H. A. Robinson & W. H. Losee. *Canada Department of Mines, Mines Branch, Report No. 723,* 1931, pages 52-77.
See *Metals & Alloys,* Vol. 2, Mar. 1931, page 74. AHE (16)

Gold and Silver as Money Metal. T. A. Rickard. *Metal Industry,* London, Vol. 40, Jan. 1, 1932, pages 11-13.
Paper read before Institution of Mining & Metallurgy, Dec. 17, 1931. An economic study of the production of gold and silver with regard to bimetallism. PRK (16)

Manganese and Manganiferous Ores in 1930. Robert H. Ridgway. *Mineral Resources of the United States,* 1930, Part 1, Jan. 25, 1932, pages 297-332.
Falling prices, decreased imports and increased domestic production characterized the 1930 Mn industry in the U. S. Domestic production of Mn ore 35% or more of Mn increased 11% to 67,035 long tons but was still insufficient for requirements. Shipments of ferruginous Mn ore were 77,417 tons (78,191 in 1929), and of manganiferous Fe ore were 707,973 tons (1,110,067 in 1929). Production of ferro Mn was 274,830 tons (339,205 in 1929) and of spiegeleisen was 87,059 tons (137,143 in 1929). (15 references). AHE (16)

The Magnesium Industry in France. (L'Industrie du Magnesium en France.) F. Ravier. *Chimie et Industrie,* Vol. 26, Dec. 1931, pages 1263-1270; Vol. 27, Jan. 1932, pages 32-40.
The author discusses the general situation of the Mg industry in France, giving his examination of the various industrial processes with practical details on the construction and operation of electrolyzers. He emphasizes particularly the importance of the principles which guide the industry, as well as some points which seem to him to be important but which are not usually found in the literature. A historical summary is given, followed by the statistics of the industry in the United States as compared with those of it in France. He includes the patents on the various processes. MAB (16)

Gold Deposits of Jakutien. (Die Goldlagerstätten von Jakutien.) N. Palutoff. *Zeitschrift für praktische Geologie,* Vol. 39, Oct. 1931, pages 121-125.
Jakutien is the north-eastern part of Siberia with an area of 4,000,000 sq. km. In the Upper Olekma district of this territory the Au production rose from 132 kg. 381 g. in 1844-48 to 400 kg. in 1915-16. In upper Timpton district from 7 tons 700 kg. for the period 1903-11 to 141 kg. 700 g. in 1922. In Ssutam district in 1899-1911 7 tons 378 kg., in 1918, 188 kg. 180 g. Upper Aldan district: no actual Au production as yet. Investigations since 1926. Aldan-Tommot district: from 1923 to 1927 a total of 1716 pud (28 tons 109 kg.) Lower Timpton district is not yet fully investigated, but Au deposits are supposed to be present. Wilui district: the Au deposits contain also Pt, and to a smaller extent Ir, Rh, Pd, Os, Rb, only about 800 kg. Au were produced since 1908. Indigirka district has definite Au deposits. Kolyma district has deposits included in granit-intrusions ab. 700x200 km. According to the origin the deposits could be divided into the following classes: 1) hypothermal deposits of quartz and pegmatit; 2) mesothermal deposits in sedimentary quartz. 3)Epithermal deposits in eruptive quartz with strong admixture of pyrites. 4) Contact deposits; 5) magmatic deposits and impregnations in eruptive rocks; 6) alluvial deposits of secondary origin in Wilui district. MISCELLANEOUS (20)

The Heat of Formation of the Nitrides, I. Manganese-nitride and Chromium-nitride. (Ueber die Bildungswärme der Nitride, I. Mangannitrid und Chromnitrid.) B. Neumann, C. Kroeger & H. Haebler. *Zeitschrift anorganische und allgemeine Chemie*, Vol. 196, Feb. 14, 1931, pages 65-78.

The experiments for measuring the dissociation pressures of the systems metal-nitrogen are described, but it seems that they can not be determined with sufficient accuracy to serve as basis for numerical calculations; the influence of formation of solid solutions on the calculation of the equilibrium from thermo-chemical formulas remains, therefore, undetermined. Ha (20)

Cold Treating Metallic Alloys. H. S. Rawdon (U. S. Bureau of Standards) *Metal Progress*, Vol. 21, Feb. 1932, pages 29-33.

The author discusses the use of liquid air and solid CO_2 as cooling agents in the production of "shrink" fits in small brass and steel parts, and as refrigerants for retarding the phase changes in duralumin rivets. Results are reported on effects of such temperatures on martensitic and austenitic steels. WLC (20)

The Temperature Variation of Intrinsic Magnetization and Associated Properties of Ferromagnetics. Edmund C. Stoner. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, Oct. 1931, pages 737-763.

Ferromagnetic phenomena are divided in 2 groups, those typified by the variation in strength and direction of the magnetization at a single temperature, with strength and direction of an applied field; and those typified by the variation of specific heat with temperature. To explain the general characteristics of both types, the existence of an intrinsic or spontaneous magnetization in the ferromagnetic which varies with temperature is assumed. The relation of this intrinsic magnetization to other properties of ferromagnetics is briefly discussed. Ferromagnetism can be regarded at ordinary temperatures as due to the interchange interaction of electron spins. Values of the magnetization, of the associated specific heat and thermoelectric power of an "idealized ferromagnetic" (one in which the magnetic properties are entirely due to electron spin interaction from absolute zero to the Curie point) are calculated and comparisons with Ni are made. 20 references. Ha (20)

The Buckling Safety of the Continuous Railroad Track. (Ueber die Knicksicherheit des lückenlosen Geleises.) Jos. Nemesek. *Organ Fortschritte des Eisenbahnwesens*, Vol. 86, Aug. 15, 1931, pages 346-350.

The possibilities and difficulties of a continuous track formed by welding are analytically treated taking into account the resistance of the road bed against horizontal and vertical displacement of the rails. Ha (20)

Electron Deflection by Metallic Films. (Ueber Elektronenbeugung an Ionenkristallen). E. Rupp. *Annalen der Physik*, Vol. 3, No. 4, 1929, pages 497-506.

Electrical measuring arrangements have been devised for studying the deflection phenomena which occur when electrons pass through thin sheets of foil, and data have been recorded in the case of a number of metals having cubic lattices, including Ni, Al and Cr. (20)

Shaft Deflection and Its Influence on Bearing Design. H. F. Shepherd. *Machine Design*, Vol. 4, Jan. 1932, pages 42-45.

The practice of mounting machine shafts is discussed and viewed under two principal classes of transversely loaded shafts, depending on whether in the expression $\sqrt{M/F}$ the factor M or F is the more preponderant; M is W/g, and F is the force required to produce unit deflection. The proper alignment or deviation from alignment in bearings is explained. Ha (20)

Experimental Study of Rigid Girders by the Method of Forced Vibrations (L'étude expérimentale des poutres a assemblages rigides par une méthode de vibrations forcées). P. Le Rolland & P. Sorin. *Revue de Métallurgie*, Vol. 28, Nov. 1931, pages 617-629.

The impossibility of calculating the secondary stresses in rigid constructions, by the means of simple loading, lead to the study of the transmission by them of periodical efforts generated from one system to another. A 2 pendulum arrangement of this type is described and the results obtained as well as theoretical considerations involved are given. JDG (20)

On Bearing Metals and Repair Work on Bearings (Ueber Lagermetalle und Lagerreparaturen). W. Schüler. *Deutsche Motorzeitschrift*, Vol. 8, Apr. 1931, pages 146-148.

Critical discussion on bearing metals with particular reference to internal combustion engines. Bearing metals high in Sn are given superiority to alloys on lead basis. Substitution alloys containing Ni, alkaline metals and compounds, graphite, Ba are usually also based on Pb. The second part of the paper treats at length 3 shop methods of casting new bearings. The potentiality of each individual method is critically discussed. EF (20)

Protection against Gases in Metallurgical Plants of the Ruhr-District (Gasschutz in den Hüttenbetrieben des Ruhrgebiets). K. Schwantke (Hütten und Walzwerks Berufsgenossenschaft). *Stahl und Eisen*. Vol. 51, Dec. 10, 1931, pages 1536-1538.

The gases of metallurgical plants are most dangerous, due to the high content of CO. Even such a small percentage as 0.1% in air may have serious effects. Whereas, in former years, the plants of the Ruhr district were only equipped with instruments to revive working men poisoned by gas, protective apparatus are now used and special instruction is given. Thus, the number of fatal accidents could be decreased from 19 in 1919 to 5 in 1930. 1 reference. GN (20)

Alliance Aluminium Compagnie. *Journal du Four Electrique*, Vol. 40, Nov. 1931, pages 429-431.

On the termination of European aluminum cartel agreement, a new society with the above name was organized in Basle in order to develop and promote the uses and manufacturing methods for aluminum. This time the cartel in addition to the old members, was joined by Canada. JDG (20)

Alloy—Mixing Explosion. *Chemical Trade Journal & Chemical Engineer*, Vol. 90, Jan 1, 1932, page 16.

A violent explosion occurred at the works of the British Thermit Co. on Oct. 21, 1931, during the mixing of the ingredients used in the manufacture of an alloy of Al and Cu. The mixing was done on an iron floor and always generated a large amount of heat. It was recommended that workmen be protected in the future with asbestos coats and that the use of iron and steel shovels for mixing be prohibited. JN (20)

Safety Workers Recommend this Self-Inspection Form. *Canadian Foundryman*, Vol. 22, Aug. 1931, pages 11-12.

A group of 12 "things to look for" in a semi-annual inspection of any plant, according to a form issued by the Industrial Accident Prevention Associations of Ontario. OWE (20)

Glass from Slag. *Glass Industry*, Vol. 6, July 1931, page 153.

A news report from Auburn, Ala., states that C. A. Basore, professor of chemistry and research of the laboratories of the Alabama Polytechnic Institute, has developed a method of using Alabama sand and granulated slag from the Birmingham blast furnace districts as ingredients for the manufacture of glass. WAT (20)

Glass from Blast Furnace Slag. *Iron & Coal Trades Review*, Vol. 124, Jan. 8, 1932, page 42.

Successful experiments have been made at the Engineering Experiment Station of the Alabama Polytechnic Institute on the conversion of blast-furnace slag into glass; the slag contains lime and silica and alumina in suitable amounts. The glass obtained is transparent, light-green or colorless, and suitable for bottles, corrosion-resisting linings and X-ray bulbs, goggles, etc. The mix to obtain good results is given, melting requires 100 to 180 minutes at 2500° to 2600° F. with subsequent annealing and slow cooling. Ha (20)

The Effect of Mercury Vapor on Sliding Contacts. R. M. Baker (Westinghouse Electric & Manufacturing Co.). *Electric Journal*, Vol. 29, Feb. 1932, pages 64-65.

The drop across contacts in a non-oxidizing atmosphere is greatly reduced by a small amount of Hg vapor. The contact behaves like a constant-ohmic resistance. It is concluded that: (1) the atmosphere surrounding a contact, whether at atmospheric or pressures as low as 50 microns, has little effect on the electrical characteristics of the contact, (2) a small amount of Hg vapor in a non-oxidizing atmosphere around a sliding contact will result in a very low contact drop, and (3) the change in the contact with the introduction of Hg vapor is such as to make it behave like a constant ohmic resistance. WHB (20)

Steel Sheetpiling Carries Tunnel Through Fault Zone. *Engineering News-Record*, Vol. 108, Mar. 10, 1932, pages 361-364.

A shield of steel sheetpiling driven horizontally, first for a top-center drift and later all around the perimeter proved successful in carrying the New York Water tunnel No. 2 through a short fault zone under the Bronx River. Driving of the 21 foot tunnel was interrupted for 6 months in the effort to progress 50 feet through a heavy water bearing section of disintegrated rock lying between formations of limestone and gneiss. CBJ (20)

Changes in the Mass-Weight Ratio of Alloys Under Compression. Peter I. Wold & Earle M. Bigsbee. *Physical Review*, Vol. 37, 1931, page 460.

Abstract of a paper read before the American Physical Society. C. F. Brush carried out experiments (Pro. Amer. Phil. Soc. Vol. 61, 1922, pages 67-183; Vol. 62, 1923, pages 75-89; Phys. Rev. Vol. 31, 1924, page 364; Vol. 33, 1925, pages 338-339) which led him to conclude that the weight of a metal may change when strained, giving a change in the ratio of mass to weight. His experimental technique seemed to preclude the obvious sources of error which might be urged as explanation of his results. At Brush's request weighings were made by the authors of certain alloys prepared by him. The procedure was practically the same as that described by Brush (Proc. Amer. Phil. Soc. Vol. 63, 1925, pages 36-50). Weighings taken on various specimens showed losses in weight when the specimens were compressed and an almost complete recovery when the stress was removed. The changes were substantially in excess to balance errors. The losses were less than found by Brush, who considered this to be due to annealing during the time between the preparation of the sample and its weighing. The shorter this time the larger were the observed effects. In the last sample studied, where elapsed time was shortest, the losses amounted to 1 part in 130,000. The results may be considered as confirming those of Brush. The suggestion that the effects are due to changes in the amount of adsorbed gases does not appear to be sufficient explanation. WAT (20)

Modern Etching Methods for Lettering of Tools. (Neuzeitliche Aetzverfahren für Werkzeugbeschriftung.) Franz Wende. *Werkstattstechnik*, Vol. 25, Mar. 1, 1931, pages 125-128.

Two methods are described by which tools can be lettered by etching and printing; this method is particularly suitable for gages which must be absolutely protected against any stress occurring in lettering by mechanical means. Ha (20)

Slag Disposal and Utilization. Fredk. Woodifield. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 125-127.

A discussion of the development of the use of slag for the manufacture of slag bricks, cement, and road material, together with a consideration of the effect of the slag composition on its physical properties. CHL (20)

Mathematical Investigation on the Distribution of Currents and Losses due to the Sheet Insulation of Transformers. (Mathematische Untersuchung über die Verteilung der Ströme und Verluste in der gegenseitigen Blechisolation von Transformatoren.) G. Stein. *Zeitschrift für Mathematik und angewandte Mechanik*, Vol. XI, Dec. 1931, pages 433-436.

Iron losses due to hysteresis and eddy currents are influential on the economy of transformers. The transformer core consists of thin sheets insulated against each other to cut down the losses due to eddy currents. The dependence of these losses on the insulation is mathematically treated. The calculation yields 20-40% of the total iron losses depending on the kind of sheet material and its thickness. EF (20)

FOUNDRY PRACTICE & APPLIANCES (22)

Die Casting or Mold Casting? (Spritzguss oder Kokillenguss?) A. Kaufmann. *Aluminium,* Vol. 13, Mar. 1931, pages 1-3.

The basic differences in the 2 methods are explained and the influence of the great difference in cooling of the 2 methods on the properties of metals with particular reference to Al is described. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 187. Ha (22)

Making Castings in Permanent Molds. J. L. Dostal (Holley Permanent Mold Machine, Inc.) *Machinery,* Vol. 38, Dec. 1931, pages 263-264.

Abstract of a paper read at the Production Meeting of the Society of Automotive Engineers, Detroit, Mich., Oct. 8, 1931. Best molds are made from the same iron that is used in the castings. Describes method of making the casting mold, which is faced with a refractory. Lists advantages which include, accuracy, uniformity, less drilling, speed. RHP (22)

Constructive Testing is an Aid to Designers of Castings. F. C. Edwards. *Foundry,* Vol. 59, Dec. 1, 1931, pages 52-55.

Abstract of paper presented at a meeting of the Institution of British Foundrymen at Derby, England. Gives results obtained from tests which show that addition of weight to casting does not always increase the strength but often reduces that property. Constructive testing is helpful since through that method it is possible to determine strength that may be expected from certain design and if necessary redesign casting to give required strength. VSP (22)

The Suitability of Different Oils as Core-Binding Materials. (Ueber die Eignung verschiedener Oele als Kernbindemittel.) H. Nipper & K. Krekler. *Mitteilungen aus dem Giesserei-Institut der technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 5 pages.

See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 23. (22)

The Conditions of Absorption and Oxidation in Small Cupola Furnaces during the Melting of Steel Scrap. (Zu- und Abbrandverhältnisse beim Einschmelzen von Stahlschrott im kleinen Kupolofen.) E. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 279. (22)

A Simple Method of Molding Hearth Rings. (Ueber ein einfaches Verfahren zum Formen von Herdringen.) E. Schütz. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, April 17, 1932, pages 156-157.

A new molding method for hearth rings is outlined which guarantees a higher production. GN (22)

Moulding A High-Duty Hydraulic Cylinder in Loam. J. J. McClelland. *Foundry Trade Journal,* Vol. 46, Apr. 14, 1932, pages 231-232.

A description of methods adopted in the molding of a heavy-duty hydraulic cylinder. OWE (22)

Cupola Melting for Non-Ferrous Alloys. T. Mauland. *Foundry Trade Journal,* Vol. 45, Aug. 6, 1931, page 90; *Fuels & Furnaces,* Vol. 9, June 1931, pages 683-684; *Foundry,* Vol. 59, July 1, 1931, pages 64-65.

Abstract of a paper presented before the Chicago Convention of the American Foundrymen's Association. See "Cupola Melting of Brass," *Metals & Alloys,* Vol. 2, Oct. 1931, page 229. OWE + Ha + VSP (22)

The Character of Sand Grains. H. Ries & G. D. Conant. *Transactions & Bulletin American Foundrymen's Association,* Vol. 2, Oct. 1931, pages 353-392.

A microscopic study was made of the sieve products of several hundred sands. It was pointed out that shape and surface of the grains undoubtedly exert an influence on the different properties of sand, such for instance as permeability, bond strength, flowing quality. One cannot determine the formation of the deposit from a study of the texture and grain characters alone. CHL (22)

The Importance of the Foundry Practice in Ship Building. (Die Bedeutung der Giessereitechnik im Schiffsbau.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Mar. 13, 1932, pages 142-143.

The article deals with the casting of heavy parts to be used for ship building. GN (22)

Light-Castings Problems. G. Moran. *Foundry Trade Journal,* Vol. 46, Mar. 31, 1932, pages 201-204.

A general discussion of the problem of the manufacture of light Fe castings. Particular attention is paid to the simplification of molding methods for the production of somewhat complicated castings. OWE (22)

Principles of Mixing and Preparing Molding Sands. (Grundsätzliches über Gattierung und Aufbereitung von Formsand.) A. Rodehueser. *Die Giesserei,* Vol. 19, Apr. 15, 1932, pages 141-145; Apr. 29, 1932, pages 163-168.

Attention is called to the importance of knowing exactly the properties of the used molding sand besides those of the new sand in order to be able to obtain from a mixture of both a molding sand of the required properties. On the basis of analysis of used sand the proportions of old and new sand are discussed according to the purpose, whether for large or small molds, wet or dry casting. The sand should be prepared only after the most favorable mixture of old sand, new sand, carbon and water have been determined; this may lead to appreciable economies in the consumption of new sand. A few examples illustrate the method of selection. Ha (22)

Chaplets and Studs in a Jobbing Foundry. Frank Whitehouse. *Iron & Steel Industry & British Foundryman,* Vol. 5, Mar. 1932, pages 229-230.

Uses for chaplets and studs described. CHL (22)

German Silver Castings of Small Thickness. (Dünnwandiger Neusilberguss.) R. Thews. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Mar. 6, 1932, pages 106-107.

Sound castings of German silver can be obtained only when the melt is properly made. On proper treatment of the melt depends: (1) the uniformity of the structure, (2) the Zn content and the Zn loss, (3) the purity of the casting, and (4) the density of the casting. Of extreme importance is the proper casting temperature. The melting temperatures vary between 1100° and 1300° C. The molding practice to be used is also discussed. In some cases it proved advantageous to re-melt the alloy. GN (22)

FURNACES & FUELS (23)

Manipulation of Electrodes of Electric Steel Furnaces. (Zur Behandlung der Elektroden in Elektrostahlöfen.) THEWS. *Die Metallbörse*, Vol. 21, June 13, 1931, pages 1108-1109.

The wear of electrodes, the significance of water cooling devices and American developments in their design are discussed. EF (23)

Heat Conservation in Iron and Steel Works. H. F. STEINBACH. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, page 128.

The advisability of the recovery of sensible heat in waste gases and of insulating all high-temperature equipment is pointed out. CHL (23)

A New Low-Temperature Furnace. *Automobile Engineer*, Vol. 22, Jan. 1932, page 26.

A brief description is given of a heat-treating furnace designed to operate between 600° to 700° C. The material is placed in a perforated container within the furnace. Uniform temperature is secured by the use of 2 thermo-couples and electric fans to keep the air circulating within the furnace. RHP (23)

Heating Furnaces—Problems Relating to Development of Construction and Operation. (Entwicklungsfragen des Ofenbaues und- betriebes unter besonderer Berücksichtigung der Wärmöfen.) ALFRED SCHACK. *Archiv für Eisenhüttenwesen*, Vol. 5, Oct. 1931, pages 193-208.

Report 155 of Heat Section of Verein deutscher Eisenhüttenleute. New developments in furnace construction and operation are discussed mathematically on the basis of heat efficiency. 21 simple formulae with illustrative problems are given for heat calculations, heat balance, losses, insulation, preheating, thermal efficiency, fuel requirements, furnace performance, fuel-bed resistance, etc. Furnace efficiency may be improved by decreasing heat loss through wall or lining or in stack-gases. Good heat protection is possible only when the refractory brick has a sufficiently high constant pressure-softening point, which is 100° to 200° C. lower than the laboratory pressure-softening point. Sensible gas loss with a given fuel depends on the operating temperature range, the efficiency of heat transfer and the specific amount of waste gases. A large combustion space with correspondingly slow traveling combustion gases will give maximum heat transfer. The amount of waste gases may be kept at a minimum and stack draft kept constant by preventing air leaks. This is especially advantageous in the open hearth furnace. The largest economy in waste gas loss is obtained by avoiding unburned fuel as far as possible; 1% CO gives waste equivalent to and increase of 90° C. in stack-gas temperature. Preheating air gives an exceptionally high amount of heat and causes a drop in stack-gas temperature. With short-flame burners stack-gas temperature decreases more than with long-flame burners. Most efficient heating is obtained if the charge is gradually built up in short time intervals in thin layers. Heating of 2 sides simultaneously is extremely effective; it is possible to decrease the heating period in some cases to ¼ of the heating time for a furnace heated on 1 side. DTR (23)

Some Aspects of the Industrial Gas Problem. G. E. WINDIATE. *Gas World*, Vol. 96, Feb. 20, 1932, *Industrial Gas Supplement*, pages 11-14.

This paper, read before the Manchester and District Junior Gas Association, Preston, Feb. 6, 1932, considers the industrial load of the gas industry and its future possibilities. The application of gas for heating purposes depends on its ease of control, consistency of supply, efficiency, cost and service. Metallurgical uses are discussed. MAB (23)

The Low-Frequency Induction Furnace and its Scope. A. G. ROBIETTE. *Metallurgia*, Vol. 4, Sept. 1931, pages 153-155; Oct. 1931, pages 175-176.

The development of the low frequency induction furnace is discussed. The vertical ring type (Ajax-Wyatt) is the one now generally used. Recent improvement in refractories permits economical melting of Ni-brass and high-Cu alloys in this furnace. It also works admirably for superheating cast Fe and is better suited for brass melting than the arc furnace because it tends to heat the coldest part of the bath. JLG (23)

The Design of Oil-Fired Crucible Furnaces. G. S. WATSON. *Foundry Trade Journal*, Vol. 46, Feb. 18, 1932, pages 117, 120.

The first principles of oil-fired crucible furnace construction are discussed, including design of burner, oil-blast inlet, combustion chamber, metal-preheating chamber and waste-products outlet. OWE (23)

Investigation and Calculation of Nozzle Burners. (Untersuchung und Berechnung von Düsenbrennern.) PAUL RHEINLÄNDER. *Archiv für das Eisenhüttenwesen*, Vol. 5, Feb. 1932, pages 407-411.

Report 159 of Heat Section of Verein deutscher Eisenhüttenleute. The mixing ratio of a burner may be calculated from discharge formula. An equation is derived by which the gas-air ratio of a burner may be calculated from the specific gravity of gas and air and the pressure drops taking place in the nozzle and in the burner head. On the basis of this equation, a simple diagram may be drawn for each burner showing, for a given kind of gas, the gas-air ratio in relation to the pressure in the burner head. DTR (23)

Gas-Fired Muffle Furnaces for Forging and Re-Heating. (Schmiede- und Wärmofen mit Ferngasbeheizung.) H. REPKY. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 13, Feb. 1932, pages 39-41.

The process of combustion with oil and coke-oven gas, including the time required to heat up, the temperature of the hearth and heat load, effect of preheating the air, compression of air, and comparison of operations in the hearth with solid and gaseous fuels are discussed. MAB (23)

The Time Required for Complete Heating of a Specimen in an Industrial Furnace. (Durchwärmezeit von Werkstücken in Industrieöfen.) VICTOR PASCHKIS. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Dec. 1931, pages 356-357.

The relationship between the temperature of the heat as it is supplied and as it reaches the specimen is discussed. Diagrams are given which give the differences in temperatures between the surface and the core of a specimen in the furnace under various furnace conditions. MAB (23)

Effect of Oxidation on Caking Properties of Coal. R. V. WHEELER & T. G. WOOLHOUSE. *Fuel in Science & Practice*, Vol. 11, Feb. 1932, pages 44-55.

Presented at Third International Conference on Bituminous Coal, Pittsburgh, Pa., 1931. Includes bibliography, 21 references. The caking properties of coals of low C content (higher O_2 content) are more readily affected by oxidation than are coals of higher C content. Oxidation insufficient to affect ultimate analyses can cause a coal of low C content to lose its caking power almost completely. With increasing C content coals become less readily oxidized, and their caking power is affected only after an appreciable change in ultimate analysis has been effected. Then the yield of oil obtained on carbonization is reduced materially. From analyses of 2 oxidized coals it is suggested that the total O content of a coal is of little value in determining caking power. DTR (23)

The Coreless Induction Furnace. (Der kernlose Induktionsofen.) G. SIMON. *Bergwerk & Hütte*, Vol. 29, Feb. 5, 1932, pages 13-15.

The dimensions, lining, operation, efficiency and advantages of coreless induction furnaces are discussed. GN (23)

Automatic Annealing Furnace. (Selbsttätiger Härteofen.) E. FR. RUSS. *Stahl und Eisen*, Vol. 52, Feb. 18, 1932, pages 172-173.

Operating details are given for the new Russ type heat treating and annealing furnace which is used for annealing steel parts that must meet rigid specification. DTR (23)

Heating Steel for Forging. C. B. PHILLIPS. (Surface Combustion Co.) *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1131-1133, 1142.

The damage done to steel in forging furnaces, consisting of oxidation, decarburizing, local carburizing, overheating, fissuring and burning, is reviewed. Diffusion combustion, properly applied, makes possible control of the atmosphere within the furnace. Air or gas are maintained in separate layers, combustion proceeding only at flame boundaries and no actual mixing taking place except at those boundaries. By causing the lowermost layer of gas to sweep over the work lying on the hearth, the steel can be heated without oxidation. In diffusion combustion, the heat is radiant as a result of the large amounts of fine C particles liberated from the fuel gas. Very rapid rates of heating are obtained, making possible increased production and reduction in the size of the furnace required with very uniform temperature distribution. MS (23)

Corner Firing of Blast Furnace Gas. OTTO DE LORENZI (Combustion Eng. Corp.) *Combustion*, Vol. 3, Jan. 1932, pages 11-16.

The excellent over-all results being obtained with blast furnace gas in modern steam generating units designed for corner firing are described. The gas burners located in the 4 corners of the lower part of the furnace are so directed that fuel streams form tangents to a small imaginary circle lying in the center of the furnace, thus imparting a rotary motion to the mixture and setting up extreme turbulence which produces thorough mixing, thus speeding the combustion process materially, reducing the time required for completing the reaction and reducing furnace volume substantially. REFRACTORIES & FURNACE MATERIALS (24)

The Specific Heat of Magnesium and Aluminum Oxide at High Temperatures. GORDON B. WILKES. *Journal American Ceramic Society,* Vol. 15, Jan. 1932, pages 72-77.

The mean specific heat of pure Al and Mg oxides has been determined from room temperature up to 1700° and 1800° C., respectively. The specimens were heated in a vertical carbon tube furnace with a magnesite tube liner for oxidizing conditions. A special calorimeter was designed and used to prevent the loss of heat by vaporization of the water when the white hot specimens were immersed. WAT (24)

50 Years Production of Refractories. (50 Jahre Herstellung feuerfester Erzeugnisse). W. STEGER. *Tonindustriezeitung,* Vol. 56, Feb. 11, 1932, pages 184-186; Feb. 15, pages 200-201; Feb. 18, pages 213-214.

The paper reviews the progress of the last 50 years in the production of refractories under the following headings: (A) dressing, (1) drying of clay, (2) crushing, (3) sieves, (4) mixing machines, (B) shaping with special reference to the various types of presses used, (C) drying and (D) burning. GN (24)

Furnace Repairs and the Storing of Refractory Bricks. (Ofenausbesserung und Lagerhaltung feuerfester Formsteine. Gesichtspunkte zur Normung der Steinformate.) E. MAASE. *Feuerfest,* Vol. 7, Feb. 1931, pages 20-25.

Furnaces frequently require repairs to various parts, particularly to those which undergo severe treatment. To order the requisite bricks, etc., from the manufacturer as required would involve a serious loss of time, so that a stock of spares must be carried, and this necessitates the storing of a large assortment of shapes and sizes in order that any emergency may be met promptly. The author discusses the standardization of shapes of refractory bricks from this point of view. WHB (24)

Heat Absorption by Refractories During Operation of Fuel-Fired Furnaces. M. H. MAWHINNEY (Electric Furnace Co.). *Iron Age,* Vol. 128, Dec. 31, 1931, pages 1678-1682, 1708.

Second of a series of 2 articles. After the interior of heating furnace has been brought up to operating temperature, heat requirement/ft.^{2} begins to vary with wall construction. Summarized from the discussion the conclusion may be as follows: (1) In fuel fired furnace for intermittent operation, the fuel required to heat to operating temperature is practically independent of usual wall construction; during operation fuel consumption is affected by refractory design; (2) During operating period, heat to refractories includes that for both radiation and absorption; (3) In a furnace operated continuously for long periods the refractory lining reaches equilibrium and the only loss of heat to refractories is the true radiation; (4) Intermittent operation lowers average heat required by refractories in comparison with a single heat. VSP (24)

Foundry Refractories. JAS. R. ALLAN. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 2, Dec. 1931, pages 569-584.

Standards for furnace refractory shapes and the allowable tolerances in sizes are discussed. CHL (24)

Refractory Coatings and Mortars. (Les enduits et coulis refractaires). L. LITINSKY. *Revue de Metallurgie,* Vol. 28, Sept. 1931, pages 277-502; *Korrosion und Metallschutz,* Vol. 7, July 1931, pages 165-167; Aug. 1931, pages 195-201; Sept. 1931, pages 210-216; Oct. 1931, pages 243-245, 249; *Chemical Trade Journal & Chemical Engineer,* Vol. 90, Jan. 1, 1932, pages 8-9; *Feuerfest-Ofenbau,* Vol. 7, May 1931, pages 65-80.

The value of a protecting refractory coating depends largely besides its composition on the nature of the binder used in it. A good protective coating must form a solid surface capable of withstanding the penetration of the corroding elements and have a good adherence to the base which can be obtained by proper regulation of the expansion coefficients of the base and the coating, which is of a particular importance in high temperature work. The nature of the coating has to be adjusted in accordance with the base supporting it. As the coefficient of dilatation changes in the same type of bricks, both due to the manufacturing methods and the manner in which they are used in the practice, the adjustment of the proper grade of the coating becomes difficult. A large number of compositions and methods is briefly described. 170 references are given. WHB+JDG+EF+JN (24)

Kaolins—Effect of Firing Temperatures on Some of Their Physical Properties. R. A. HEINDL, W. L. PENDERGAST & L. E. MONG. *Bureau of Standards Journal of Research,* Vol. 8, Feb. 1932, *Research Paper* 410, pages 199-215.

Samples of 5 kaolins, representing some of the important world sources, were fired at 8 different temperatures ranging from 1,100° to approximately 1,650° C. The chemical analyses and pyrometric cone equivalents (softening points) were obtained on the raw materials, the thermal expansion, porosity and specific gravity on the fired materials, and the petrographic analyses on both the raw and fired. X-ray diffraction patterns were made of Georgia, North Carolina, and Mexican (dickite) kaolins, mullite, and cristobalite. WAT (24)

The Melting Points of Zirconiumoxide and Hafniumoxide. (Ueber die Schmelzpunkte des Zirkonoxyds und des Hafniumoxyds.) P. CLAUSING. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 204, Feb. 9, 1932, pages 33-39.

The oxides were melted by placing them in holes in a W rod and heating the latter electrically; the temperatures were determined with a pyrometer of Hobborn-Kurlbaum type. The melting points were determined to 2950 ± 20°K for ZrO_2 and 3047 ± 25°K for HfO_2. A comparison with more recent determinations gives a good agreement, but not so with older measurements. 13 references. Ha (24)

Trade Names in the Fields of Refractory Materials. (Markenbezeichnung im Feuerfest-Fach und Ofenbau.) *Feuerfest-Ofenbau,* Vol. 7, Sept. 1931, pages 136-141.

Trade names of all kinds of materials connected with furnace construction and refractory industry of German and International origin are compiled and briefly characterized. EF (24)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Scaling of Carbon Steels at High Temperatures. G. W. AKIMOV. *Transactions of the Central Aero-Hydrodynamical Institute,* No. 90, 1931, 44 pages, 44 illustrations. (In Russian).

Specimens of 0.14, 0.6, 1.12 C steels and 3.5% C cast iron (whether white or gray not given) were heated in an oxidizing atmosphere under varying time and temperature. Using 500° and 800° C. and determining the amount of oxidation by the increase in weight corrected for carbon elimination it was found that the parabolic law is applicable only to the beginning of scaling after which it follows a straight line with a rapid upturn after 35 hours. The speed of decarburization and scale formation is different. On longer heating the ferrite forming the decarburized zone is composed of long radial crystals. Radial structure is produced as the metal to metal contact along radial grain boundaries is prevented by the stream of reaction gases coming from the area of reaction—the boundary between decarburized layer and original metal. Changing the temperatures to 400° and 900° C. showed that under 600° C. decarburization and scaling are the same, between 600° and 850° C. the speed of decarburization sharply increases while above 850° C. the speed of scale formation increases so fast that the decarburized layer totally disappears. A sharp break in the oxidation curve is found between 800° and 850° C. corresponding to the transformation range and showing that speed of oxidation of γ iron is lower. Water vapor in the scaling atmosphere rapidly increases the reaction. Temper color formation was used as a means of determination of scaling qualities of quenched and annealed steels. Quenched steel scales slower than steel which has been annealed. Surface condition has no influence. Deformation strongly affects the uniformity and speed of scaling. (29)

The Change in Resistance of Graphite, Thorium, Titanium and Titanium-Zirconium between 20.4° K. and 1.1° K. W. J. DE HAAS & P. M. VAN ALPHEN. *Proceedings Academy of Science, Amsterdam,* Vol. 34, Jan. 31, 1931, pages 70-74.

Samples about 15 mm. long were prepared from a block of Ceylon graphite, with the principal axis perpendicular to the direction of the current. The change in resistance near the temperature of liquid He was slight. At 1.1° K the value of R/R. was about 0.12 and this remained nearly constant up to 5° K after which it increased gradually to approximately 0.214 at 20.4° K. Measurements on a part of a single crystal of Th indicated that it became supra-conducting at 1.4° K. In the region between 1.4° and 1.9° K the resistance increased gradually until it acquired its normal resistance at the upper temperature. These results differ considerably from those obtained by Meissner for another part of the same crystal. The resistance of Ti falls rapidly from 1.88° to 1.63° K at which temperature it becomes supra-conducting. The resistance of the Ti-Zr solid solution decreased rapidly between 1.63 and 1.12° K at which point it becomes supra-conducting. It is difficult to obtain reproducible results with these metals. WHB+WAT (29)

Heat Resistant Alloys for Boiler and Engine Construction. (Hochhitzebeständige Legierungen für Dampfkessel- und Maschinenbau.) Br. Schulz. *Brennstoff- und Wärmewirtschaft*, Vol. 13, Feb. 1931, pages 26-28.

Considers special steels with low additions of Mo, V and Al as heat-resistant material. Tests on scaling and physical properties carried out at elevated temperatures by the Material Prüfungsamt Dahlem on the following steel are given: 0.14 C, 0.24 Si, 0.34 Mn, 0.72 Cr, 0.21 V. Calls attention to Sicromal of the Vereinigte Stahlwerke, employing only 6 Cr instead of 15 Cr, with an addition of 0.9-3% Al. Properties of the following representative steel are presented: 0.06 C, 0.3 Mn, 0.4 Si, 0.9 Al, 5.8 Cr, 0.4 Mo and 0.05 V. Tests of Wiburg on 7 different heat-resistant steels are reviewed including low C (0.5-0.15% C), martensitic and austenitic steels and the 2 Heraeus alloys B-7-M with 15 Cr, 61 Ni, 7 Mo, 15 Fe, 2 Mn and Grade B with 15 Cr, 64 Ni, 20 Fe, 1 Mn. The Krupp steels of martensitic (V-M) and austenitic structure (V-A, NCT, FF) are discussed and practical experiences with V-steel, the surface of which is enriched in Al, are given. In conclusion the present state of heat-resistant material used for turbine blades is considered. EF (29)

Considerations and Tests for Cast Materials for High-Temperature High-Pressure Service. L. W. Spring. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Oct. 1931, pages 13-55.

The author points out that castings have certain inherent qualities which other materials, seemingly, do not possess. They are more resistant to "creep" at temperatures above the strain hardening range than wrought materials of identical composition. A large number of short and long time tensile test results are given on cast and wrought materials. Other considerations, which influence the development of high temperature high-pressure service materials are discussed. See also *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 26. CHL (29)

Use of Metals at Elevated Temperatures. Clyde E. Williams. *Brick & Clay Record*, Vol. 80, Apr. 1932, pages 195-197.

The heat resistance requirements for metals used in kilns, dryers and fans are outlined. The types of metals used for the various requirements and the protective measures taken are discussed. See also *Metals & Alloys*, Vol. 2, Sept. 1931, page 192. CBJ (29)

The Properties of Copper in Relation to Low Stresses. The Effect of Cold-Work, Heat-Treatment, and Composition. Part II.—Creep Tests at 300°C. and 350°C. of Arsenical Copper and Silver-Arsenical Copper. H. J. Tapsell & A. E. Johnson. *Institute of Metals, Advance Copy* No. 599, Apr. 1932, 6 pages.

Creep tests were made on 2 alloy coppers. One contained 0.34% As and no Ag. The other contained 0.31% As and 0.072% Ag. They were both given the pre-treatment described in Part I, which consists in cold working to a reduction of about 5% followed by an anneal at 300° or 350° C. It was found that the pre-treatment improved the resistance to creep at 300° and 350° C. and that the Ag-bearing Cu was superior to the Ag-free material. 2 references. JLG (29)

Materials but Little Subject to Aging Phenomena, for the Construction of Boilers (Gering alterungsempfindliche Kesselbaustoffe). *Wärme*, Vol. 54, Jan. 3, 1931, pages 6-7; *Chemie et Industrie*, Vol. 25, June 1931, page 1386.

Izett steel is claimed to be practically not subject to aging phenomena. Alloy steels (particularly 3-5% Ni steels, low C steels containing V or Mo, 0.6-0.8% Cu steel containing 0.4-3% Cr) stand up well against both corrosion and high temperature. This permits of the reduction of the thickness of the boiler shell, thus improving heat transmission which compensates for the extra cost. The steel can be tested by aging artificially by 10% cold stretching, followed immediately by annealing 30 min. at 200° C. WHB (29)

Material Problems Involved in Radiation Super-Heaters. (Die Materialfrage bei Strahlungsüberhitzern.) K. Adloff. *Die Röhrenindustrie*, Vol. 24, Mar. 12, 1932, pages 61-62.

After reviewing recent trends in super-heater designs and the requirements to be met with by materials employed, tests in the Power Station Klingenberg are reported on super-heater tubes. At first Izett steel of 36 kg./mm.² tensile strength and 25% elongation was used. The wall thickness of the tubes was 6 mm. After 635 hours service, the tubes were warped to such an extent, that they had to be exchanged. Then open hearth steel of 41 kg./mm.² and 25% elongation was employed, the wall thickness of the tubes being 4.5 mm. Only tubes which were shielded by cast plates withstood the strain. Now a 6% Cr, 0.4% Mo steel of 50-55 kg./mm.² is selected. It has not been decided yet whether or not continuous operation is possible with wall temperatures above 550° C. The stresses in these super-heater units are discussed. The satisfactory solution of this problem is up to the metallurgist. High alloy steels permit a wall size reduction of about 25% and diminish the critical stresses caused by the great differences in temperature between the inside and outside of the tubes. EF (29)

Further Data on the Thermal Diffusivity of Nickel. Richard H. Frazier. *Physical Review*, Vol. 40, May 1932, pages 592-595.

Results are given of tests for determining the thermal diffusivity of 99.25% Ni. The work is part of a program of thermal measurements aimed toward the measurement of the Thomson effect. The results and conditions of the test are discussed. WAT (29)

little influence on endurance. No information on endurance of notched specimens or on corrosion-fatigue of copper containing additions, are on record.

No accelerated endurance test for non-ferrous metals and alloys has yet been found to give fully reliable data. The tests should run to 100 million cycles or at least to 50 million plus further test at an increased stress to show whether damage or improvement has occurred. Especially on cold-worked material, tests of one form and temper, e. g., sheet, do not necessarily give valid information for other forms and tempers.

Much more work of a very tedious nature is necessary to clarify the engineering problems involved.

Manufacturers' Literature Reviews

466 **Structural Aluminum**—A supplement to their Structural Aluminum Handbook has been issued by the Aluminum Company of America, Pittsburgh, Pa. It contains additions to the tables in the Handbook as well as new data which were not available at the time the Handbook was published.

467 **Wrought Pipe**—A leaflet recently issued by the National Tube Co., Pittsburgh, Pa., lists ten points of superiority of their pipe, among them being its strength, ductility, uniformity, freedom from scale, etc. Their galvanized pipe is given a special chromate treatment to resist discoloration and the formation of white rust.

468 **Nickel Steel**—The July issue of *Nickel Steel Topics*, published by the International Nickel Co., New York, N. Y., features an article describing the use of nickel steel in free wheeling units for automobiles. A number of applications of this steel to oil well equipment are also illustrated.

469 **Heating and Cooling Wire**—Bulletin 339 of the W. S. Rockwell Co., New York, N. Y., is a reprint of a paper presented to The Wire Association on the Methods of Heating and Cooling Wire. It is a very thorough discussion of this subject and is well illustrated.

470 **Welded Tubing**—The Carpenter Steel Co., New York, N. Y., has sent out a leaflet devoted to their welded tubing made from cold rolled stainless strip steel. The leaflet includes general information on this tubing, its physical properties and working instructions.

471 **Welding**—The August issue of *Oxy-Acetylene Tips*, published by the Linde Air Products Co., New York, N. Y., features an article entitled "Oxwelding Brass and Bronze." Another article in the same issue is "A Simple Cost System for the Repair Shop." The feature article in the September issue is "Economy for the Beet Sugar Industry."

472 **Blooming Mill Equipment**—Bulletin A-701 of the United Engineering & Foundry Co., Pittsburgh, Pa., is a 35-page, fully illustrated booklet discussing their blooming mill equipment for all duties where a large mass of metal is to be roughed down rapidly for finishing to smaller shapes.

473 **Nickel-Clad Steel**—A booklet just published by the Lukens Steel Co., Coatesville, Pa., illustrates various applications of nickel-clad steel in chemical and industrial processing equipment, in the textile industry and in general industrial service.

474 **Shield-Arc Welder**—A bulletin just released by the Lincoln Electric Co., Cleveland, Ohio, describes their new "Shield-Arc" welder which makes possible improved quality and speed of welding.

475 **Foundry Equipment**—Catalog No. 540 of the Jeffrey Manufacturing Co., Columbus, Ohio, describes and illustrates how various types of foundries have been modernized by the installation of Jeffrey foundry machinery. Typical arrangements of equipments are pictured by perspective drawings. The kinds of equipment discussed include continuous core handling equipment, trolley conveyors, crushing and pulverizing equipment, sand mixers and sand conditioners.

476 **Tensometers**—Bulletin 37 of the Baldwin-Southwark Corp., Philadelphia, Pa., covers their line of lever type strain gages known as Huggenberger Tensometers. A short technical discussion of the fundamental principles of these instruments is followed by data and suggestions concerning application of the various types of Tensometers. A section describing the methods of mounting and using Tensometers is included. Bulletin 40 published by the same company describes their Scratch Extensometer which weighs less than an ounce, is hardly larger than a teaspoon, may be attached to light as well as heavy structures, is recording and can be purchased for less than $50.

477 **Portable Hardness-Testing Instruments**—Bulletin No. H-4 of the R. Y. Ferner Co., Washington, D. C., describes the Duroskop and the dwarf Brinell press. The former can be used for testing many materials, from tempered steel to refined lead, as well as linoleum, rubber, wood, etc. The latter may be used for all testing done with the larger Brinell instruments with the added feature that it is portable.

478 **Nickel-Clad Steel Plate**—Bulletin T-4 sent out by the International Nickel Co., New York, N. Y., is entitled "Methods for the Fabrication of Nickel-Clad Steel Plate." Full information on the subject is given. The bulletin was prepared by their research department and is one of their technical bulletin series.

479 **Automatic Temperature Control**—Bulletin 177 sent out by the Foxboro Co., Foxboro, Mass., is entitled "Temperature Controllers" and gives a complete description of the operating principles of their controllers together with construction features. The various types are illustrated and described and each part of the controller is discussed at length.

480 **Liquitol**—Several leaflets have been issued by the Alpha-Lux Co., Inc., New York, N. Y., which pertain to their "Liquitol" which is to be used in the production of iron and steel castings and steel ingots. It is a fine black powder which is sprinkled over the surfaces of the molten metal in the heads and runners.

481 **Testing Precious Metals with the Touchstone**—An attractive booklet of this title has just been prepared by the Jewelers' Technical Advice Co., 22 Albany St., New York, N. Y. It comprises a succinct but exhaustive text on practical testing of the precious metals. The methods described have been thoroughly tested and are simple but effective. Price $1.00.

482 **Thermometers**—Catalog 1204 of the Bristol Co., Waterbury, Conn., is devoted to their vapor tension type thermometers. It is intended to be not only a summary of these instruments as made by them, but a handbook of reference for those engaged in specifying or recommending recording and controlling instruments.

483 **Tempering Spring Washers**—A leaflet issued by Leeds & Northrup Co., Philadelphia, Pa., describes the installation of five Homo tempering furnaces used by the National Lock Washer Co. Another leaflet by the same company describes Homo tempering for parts and tools and Hump hardening as used by an instrument manufacturer.

484 **Manganese Bronze**—The July issue of *Better Castings*, published by the Niagara Falls Smelting & Refining Corp., Buffalo, N. Y., gives instructions for making manganese bronze with "Falls" No. 21 manganese bronze hardener. The procedure using new metals and new metals with scrap is detailed.

485 **Electric Furnaces**—The Pittsburgh Electric Furnace Corp., Pittsburgh, Pa., is distributing reprints of "Duplexing With Cupola Makes High Grade Iron Castings" which appeared in *Iron Age*.

486 **Gas-Electric Sets**—Publication C 1959 of the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., describes and illustrates gas-electric sets, listing their mechanical features, ignition and control. They are designed for furnishing continuous or auxiliary power supply for mines, barges, dredges, oil and gas wells, etc.

487 **Bunsen Spectroscope**—A leaflet recently sent out by Bausch & Lomb Optical Co., Rochester, N. Y., describes the construction of their Bunsen spectroscope designed for the use of teachers. Mention is also made of their laboratory wave length spectrometer.

488 **Superheaters**—Bulletin T-22 of the Superheater Co., 60 East 42nd St., New York, N. Y., discusses the Elesco superheaters for horizontal return tubular boilers. A table shows results of tests in a plant using these superheaters.

489 **Nickel Alloy Steel Castings**—Bulletin No. 8-A of the International Nickel Co., New York, N. Y., discusses the applications of nickel steel castings, the design of these castings, the effect of alloying elements on cast steels, the methods of adding alloys to steel and the heat treatment of the castings. The pamphlet is one of their Nickel Steel Data and Applications Series.

490 **Furnaces**—Bulletin 333 of the W. S. Rockwell Co., New York, N. Y., is devoted to their belt-conveyor type continuous furnaces, both electric and fuel-fired. Bulletin 334 of the same company gives data on their non-ferrous billet heating furnace.

491 **Oilstones and Sharpening Stones**—A leaflet prepared by the Pike Manufacturing Co., Pike, N. H., shows their different powered oilstones and the method of using them for various tools.

492 **Brazing Alloy**—Bulletin No. 7 of Handy & Harman, New York, N. Y., describes their Sil-Fos, a low melting point brazing alloy which makes strong, sound, corrosion-resisting joints on copper, brass, bronze, nickel, Monel metal and other non-ferrous metals or alloys.

493 **Sodium Perborate**—The Roessler & Hasslacher Chemical Co., Niagara Falls, N. Y., have published a 16-page booklet entitled "Properties and Uses of R & H Sodium Perborate." The presence of 1/20 to 1/50 oz. of this chemical per gallon of nickel plating solutions stops hydrogen pitting, according to this booklet. In the alkaline tin bath and sulphate zinc bath, pleasing white plate is produced through the presence of small amounts of sodium perborate in the plating solution.

494 **Smoke Recorder**—The application of the Micromax potentiometer for this purpose is discussed in a folder prepared by Leeds & Northrup Co., Philadelphia, Pa.

495 **Fuel Governor**—A leaflet describing an engine governor with remote setting for speed has been sent out by the Pickering Governor Co., Portland, Conn.

496 **Motorized Speed Reducer**—The Link-Belt Co., Chicago, Ill., has recently sent out a leaflet announcing a new motorized speed reducer which has been added to their line. The reducer illustrated is a triple reduction unit with a speed ratio of 312.2 to 1. The motor shaft operates at 1165 r.p.m., and the low speed shaft at only 3.75 r.p.m.

497 **Chromium Plating**—The August 1932 issue of *The Udylite News*, published by the Udylite Process Co., Detroit, Mich., features an article on Udylite as applied to the manufacture of radio condensers.

498 **Graphic Meters**—Bulletin No. 4321 of the Esterline-Angus Co., Indianapolis, Ind., contains an article entitled "Determining the Cost of Power and the Maximum Load Conditions Throughout a System." Bulletin 12302 of the same company describes the reactive volt ampere meter and its uses on the power system while bulletin 1227 is devoted to their frequency meter.

499 **Diesel Electric Locomotives**—The Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has published an illustrated folder describing the use of Diesel electric locomotives in the steel industry and covering the economies effected thereby. Folder DMF-5449.

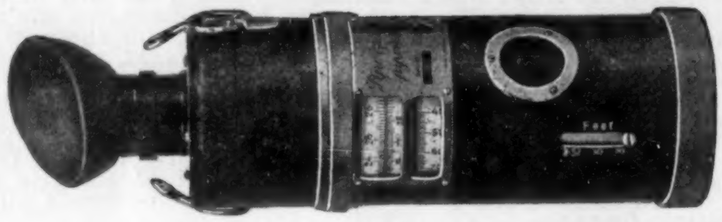
PYROMETERS

RADIATION

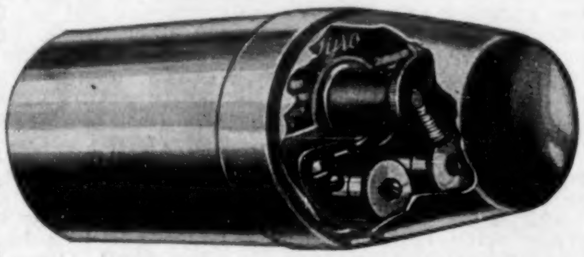
Portable. Sight into furnace or at the material, and within 3 seconds you have automatically a true temperature indication. Stock ranges: 1000-2600°F. 1400-3600°F.

OPTICAL



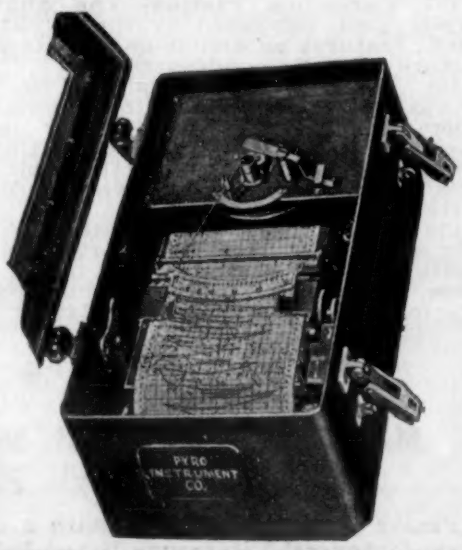
The only self-contained, direct reading Pyrometer. Concentrated test mark permits precision temperature readings of minute spots. Stock ranges: 1400-2400°F; 1800-3300°F; 1400-2200°F and 1900-3400°F.

TUBES—RADIATION



Standard or Super-Sensitive. Proven economical as compared with thermocouples when measuring high temperatures. Super-Sensitive Tubes have time lag of approximately 1 second.

RAPID RECORDER



Especially designed to record instantly quick-changing temperatures when measured with our Super-Sensitive PYRO RADIATION TUBE.

Basic Principles of Metallurgy Discussed by Steel Treaters. Part II, Part III. *Fuels & Furnaces*, Vol. 9, Nov. 1931, pages 1295-1299; Dec. 1931, pages 1407-1412.

Presents abstracts of lectures delivered to young men without technical education as part of a course sponsored by the Pittsburgh Chapter of the American Society for Steel Treating. S. L. Goodale discusses metallurgical terms, crystallization and metal structures, structures and properties of pure metals and hot and cold working. Norman Woldman discusses the Fe-C diagram and straight C steels. N. I. Stotz describes heat treating operations and J. A. Succop deals with mechanical shaping of metals. V. N. Krivobok discusses alloy steels other than high-speed and stainless steels and structures and properties of alloys. MS (0)

The Joy of Ignorance. T. SWANN HARDING. William Godwin, Inc., New York, 1932. Cloth 6 × 9 inches, 369 pages. Price $3.00.

This book will make much of your bliss evaporate. Harding decided to investigate the fallacies and fictions promoted by popular slogans and the nostrums endorsed by plausible quacks.

When you learn that coffee isn't "mighty bad for you" and "coffin nails" are not lethal, when you cease to believe that spinach is good and pie is suicidal, the pillars of your faith are beginning to totter and no one knows where you will end.

You will probably save money and be more comfortable without your bogies and superstitions. Harding's book is a mental disinfectant and provides enjoyable reading.
Richard Rimbach (0) -B-

Specifications for Quality Metals, How to Write Them. F. M. RANDLETT. *Metal Progress*, Vol. 21, May 1932, pages 44-45.

In drawing a specification a minimum number of requirements consistent with a satisfactory product should be included. The wording should be without ambiguity and should provide for inspection and tests for the protection of the consumer. WLC (0)

Metallurgical Developments in 1931. T. M. SERVICE. *Iron & Coal Trades Review*, Vol. 124, Jan. 22, 1932, pages 154-155.

The research carried out in England and elsewhere on the heterogeneity of steel, the solidification and crystallization of steel ingots, balanced reactions in steel manufacture, corrosion of iron and steel, and the behavior of steel under stress at high temperature is briefly reviewed. Ha (0)

Research and Development in Metallurgy. C. E. MACQUIGG. *Journal Franklin Institute*, Vol. 213, June 1932, pages 583-604.

Brief survey of research and development in metallurgy stressing the commercial aspects, and discussion based on conditions in the U. S. The first tensile strength in 1837 was determined by transverse tests. Tensile strength, ductility, hardness, resilience, electrical properties, behavior toward corroding media, fatigue, are the qualities of metals and alloys about which information is generally sought. The purpose of metallurgical progress is at least 3-fold, namely: (1) to cheapen or otherwise improve the processes for obtaining metals from their natural state or to discover new processes; (2) to obtain metals or their combinations that will serve in applications or new needs of industry in which existing materials, partly or wholly inacceptable, and to improve the qualities of metals and their alloys; (3) to multiply the uses to which the present products can be legitimately applied. Mention is made of new tests and applications such as "creep," shock testing, X-ray, metallographic tests, light alloys, new steel alloys, corrosion resistant steels, etc. 28 references. DTR (0)

Modern Tendencies Regarding the Methods of Study of Metals and their Alloys (1928-1930). (Les tendences récentes relatives aux méthodes d'étude des métaux et de leur alliages [1928-1930].) LÉON DLOUGATCH. *Revue de Métallurgie*, Vol. 29, Apr. 1932, pages 215-220; May 1932, pages 276-279.

A brief survey of the tendencies, which can be observed in the world's work on metals and their alloys as far as the methods of study are concerned. JDG (0)

Steel Control (Die Stahlkontrolle). R. ESCHELBACH. *Die Werkzeugmaschine*, Vol. 36, Mar. 31, 1932, pages 99-102; Apr. 15, 1932, pages 124-126.

Report from the Metallographic Institute of the Mining Academy at Clausthal, Germany. The article gives a detailed description of how the production of a German quality steel mill is controlled in order to process products of high quality. The points dealt with in particular are supervision of the casting temperature of the ingots, supervision of the rolling temperature, data are given on the most suitable rolling temperatures for the various types of steel, supervision of forging with data on suitable forging temperatures, methods of control of the various steels in heat treating. The procedure is outlined for alloy and plain case carburizing steels, Cr structural steels, tool steels, high speed steels. The spark test and mechanical testing are emphasized. GN (0)

PROPERTIES OF METALS (1)

The Changes of Electric Conductivity of Ferromagnetic Materials in Magnetic Fields (Die Aenderungen der elektrischen Leitfähigkeit ferromagnetischer Stoffe in Magnetfeldern). O. Stierstadt. *Zeitschrift für Technische Physik,* Vol. 13, No. 3, 1932, pages 105-111; No. 4, 1932, pages 161-165.

Ferromagnetic phenomena are discussed in the light of the newest theories of Sommerfeld, Fermi-Dirac, Weiss and others. For the details of the exhaustive investigation the paper must be referred to. The general conclusions are as follows: The change of resistance of all metals including ferromagnetics is, at sufficiently low temperatures, always positive, both in longitudinal and in transverse magnetic fields. All anomalies are explained and it is found that the sign of the induced magnetism in a metal is not a question of the direction but of the strength of the magnetizing field. Also the sign of the change of resistance of ferromagnetic materials in magnetic fields is explained by the theory; at room temperature it is positive in weak longitudinal fields, negative in strong transverse fields. The opposite conditions will not be sufficiently clear until further measurements have been made. The influence of temperature is also still to be determined more exactly. 20 references. Ha (1)

Beryllium and Beryl. Official publication, the Imperial Institute. His Majesty's Stationery Office, London, 1931. Paper, 26 pages. Price 6d.

Brief summary of properties of metallic Be, methods of production, alloys, compounds, deposits of beryl in various countries. A bibliography is appended. Cu-Be alloys are suggested for springs and bearings. Bearings with 1 to 2% Be are said to show less wear than those of Sn bronzes. Much of the data in the pamphlet is elsewhere available. HWG (1)

Useful Information About Lead. Lead Industries Association, 420 Lexington Ave., New York, 1931. Cloth, 6 × 9 inches, 104 pages. Price 50 cents.

This publication describes concisely the story of Pb and its principal uses. Short chapters are devoted to the major industries consuming Pb, and the part Pb plays in them, as well as the history, mining, smelting and refining of the metal. The table of the properties of Pb is probably the most complete and up to date ever published. The lead compounds are dealt with to some extent in regard to their characteristics, manufacture and uses. Many corrosive chemicals handled in Pb equipment are listed and typical formulae of important classes of alloys are given. WAT (1) -B-

Molybdenum, the Metal that Talks. *Electrical Engineering,* Vol. 51, May 1932, pages 311-312.

A brief description of the uses of the metal in recent times, its deposits and production from ores and prospective further applications. In steel it can be substituted for W in a ratio of 1:2; use of the high strength of Cr-Mo steel is made in steel tubing. The pure metal is used extensively in the incandescent and radio bulb industry. It finds use also in the chemical and dye industry. Ha (1)

Tantalum and Its Applications. (Le tantale et ses applications.) L. Triau. *Aciers Spéciaux, Métaux et Alliages,* Vol. 7, Jan. 1932, pages 15-17.

History of the discovery and isolation of Ta. Its uses and properties are also reviewed. Its chief property is its resistance to corrosion by acids or alkalies. GTM (1)

Studies of Italian Aluminum. (Richerche sull' alluminio Italiano.) O. Scarpa. *Alluminio,* Vol. 1, Jan.-Feb. 1932, pages 3-14; Mar.-Apr. 1932, pages 73-79.

Italian Al for electrical conductors is stated to run 99.5-99.7% Al, with Fe from .10 to .30, Si .10 to .15, Ti trace to .10. Conductivity tests on 342 samples of wire showed resistance at 20° C. from 2.79 to 2.93 microhms/cm, with about 4% falling below 2.82 and about 5% above 2.89. The average is about 2.845. A frequency curve of resistivity shows about the same form as one for foreign Al. The density of Al wire, reduced to H_2O at 4° C. ran from 2.703 to 2.707. Part II. The effect of annealing on the electrical conductivity, strength and density of wire made from Italian Al was found to agree with results on Al conductor wire in general. Curves are plotted for resistivity and for tensile strength vs. annealing temperatures (4 hr. anneals). A frequency curve for decrease in resistivity on annealing shows a maximum at 2.25% decrease, but the curve is not symmetrical, perhaps 20% of the specimens showing 3.0 to 3.7% decrease, while with a symmetrical curve, there would have been none above 3%. HWG (1)

Theory of Metals. I. Proper Values and Proper Functions of the Linear Atomic Chain. (Zur Theorie der Metalle. I. Eigenwerte und Eigenfunktionen der linearen Atomkette.) H. Bethe. *Zeitschrift für Physik,* Vol. 71, Aug. 15, 1931, pages 205-206.

A theoretical treatment showing how the proper functions of zero approximation and the proper values of first approximation can be calculated. Ha (1)

Magnetostriction Measurements using a Heterodyne Heat Method. A. B. Bryan & C. W. Heaps. *Physical Review,* Vol. 37, Apr. 1931, pages 466-467.

The changes of length in a longitudinal magnetic field were measured of crystals of Ni, Fe, magnetite and hematite and Bi. Former measurements of Ni and Fe were confirmed, magnetite expands in 2 directions and contracts in the third, hematite shows a slight expansion, while Bi does not show any change at all even for fields higher than 2000 gauss. Ha (1)

Molybdenum. Alice V. Petar. *United States Bureau of Mines Economic Paper* 15, 1932, 38 pages.

The properties; uses; occurrence; mining, milling and manufacturing methods; foreign and domestic production, markets, etc. for Mo are discussed. An extensive bibliography is given. AHE (1)

The Search for New Alloys. Leland D. Case. *Rotarian,* Vol. 40, May 1932, pages 26-28, 52-54.

The process of making Mg metal from Epsom salts is briefly described and the uses of Mg alloys and their characteristics, especially for airplanes, because of their extreme lightness are explained. Ha (1)

PROPERTIES OF FERROUS ALLOYS (3)

Tool Steels (Les Aciers D'outillage). J. Laymarie. *Aciers Spéciaux, Métaux et Alliages,* Vol. 7, Feb. 1932, pages 69-77.

A general review and classification of tool steels. GTM (3)

The Effect of Annealing on the Mechanical and Magnetic Properties and Electrical Conductivity of Cold Drawn Steel. (Ueber den Einfluss des Anlassens auf die mechanischen und magnetischen Eigenschaften sowie die elektrische Leitfähigkeit kaltgezogenen Stahles.) Werner Köster & Herbert Tiemann. *Archiv für das Eisenhüttenwesen,* Vol. 5, May 1932, pages 579-586.

Tests made on 7 steels, C running between 0.03 and 0.95%. The Si was below 0.2%, Mn between 0.3 and 0.7% and P + S was less than 0.035%. Steel wires 5.3 mm. diam., in both annealed and patented state, were drawn cold and given 0, 20, 50 and 80% cold roll reduction. After being drawn the wires were stored for about one month, and then the mechanical, magnetic and electrical properties were studied after annealing up to temperatures 950° C. The rise of the yield point and tensile strength between 200° and 300° C. was greater for patented steel than for annealed material; these properties were apparently independent of amount of cold roll reduction and increased with increasing C content. For high C-steel with 80% cold roll reduction, the elongation begins to drop at 450° C. and reaches a definite minimum value at 525° C. The reason for this decrease in elongation lies in the distinctive rate of decrease in yield point and tensile strength. The resistance to compression of patented steel reaches a minimum between 450° and 500° C., and then rises with greater cold roll reduction and higher % C. This characteristic appears to be a simple weakening process, the reverse of this taking place when the steel is later cold drawn. The drop in coercive force on annealing is retarded in the temperature range between 400° and 550° C. and the more so the greater the amount of drawing and the higher the carbonization of the steel. The retarding finally changes over into an increase of coercive force. Patented steel shows this phenomenon even much more than annealed material. It is attributed to the fine small-pointed distribution of cementite within these temperature limits. The remanence rises regularly with the annealing temperature. The rise begins and ends with increasing change in form at low temperatures, and the maximum value of remanence rises in the same direction. The electrical conductivity rises on annealing above 400° C. and reaches a maximum at 550° to 680° C. After passing beyond the A_1 point, the conductivity drops back to its initial value. The rise is attributed to the conversion of cementite from the laminated into the spherical shape. 19 diagrams and 9 references. DTR (3)

Manganese Steel, Its Structure and Properties (L'acciaio al manganese, sua struttura e proprieta). G. Guzzoni. *La Metallurgia Italiana,* Vol. 24, Mar. 1932, pages 173-186.

32 references. Evidence is presented that, in the austenitic Hadfield steel, heating to below the Ac_1 point tends to produce first precipitation of carbide, then (following the impoverishment of the matrix in Mn and C) the formation of troostite. Further heating above Ac_1 produces further precipitation of carbide. The formation of troostite is direct, not through martensite, and the common terminology by which the decomposition product of austenite in these steels is termed martensite, has arisen through the acicular structure of the carbide needles. The mechanical properties of the steels are better with lower C and higher Mn; 0.85-0.95% C and 12-14% Mn gives better results than 1.0-1.35% C. 11.5-12% Mn. Resistance to abrasion is best with a pure austenitic structure. It falls if the austentite has started to decompose. Interesting micrographs are shown of an Amsler wear-test specimen whose cold-worked surface shows slip lines. After heating 3 hours at 600° C. precipitation occurred along the slip lines while in a similarly heated, un-worked specimen, precipitation was along the grain boundaries. See also *Metals & Alloys,* Vol. 3, July 1932, page MA 197. HWG (3)

Production and Properties of Superior Cast Iron. Oliver Smalley. *Metal Progress,* Vol. 21, May 1932, pages 49-54.

The author describes the properties of high strength cast irons made by addition of large amounts of steel to the charge and the addition of measured amounts of calcium silicide in the ladle. Such modern irons show good elastic properties compared to other cast materials and weld metal. Castings are sound and of uniform hardness with thin plate graphite uniformly distributed in a matrix of eutectoid steel which is capable of property development by heat treatments the same as steel. Applications are discussed. WLC (3)

Non-Rusting and Heat Resistant Chromium-Cast Iron Alloys. (Ueber nichtrostende und hitzebeständige Chrom-Gusseisen-Legierungen.) R. Wasmuht. *Stahl und Eisen,* Vol. 52, Apr. 7, 1932, pages 346-347.

Originally published in *Kruppsche Mh.* 12 (1931) pages 331-337. Cast iron alloys with Cr above 30%, and C between 1 and 4% were studied. Ledeburite was present with 1% C. With 2%C and 34% Cr the cast iron was weakly subeutectic, and with 3% C, Cr-cementite $(CrFe)_7C_3$ had precipitated out. Eutectic was at 2.4% C. Corrosion resistance of these low C-cast iron alloys was practically similar to that of non-rusting steels. Alloys show characteristic cast iron behavior. Breaking strength 40-50 kg./mm.^{2}, Brinell hardness 250 to 350, depending on C-content. Several tests were made on strength at high temperatures, shrinkage, sp.gr., etc. Several examples of machining and welding of alloys are included. DTR (3)

Stainless Steels—Their Fabrication and Welding. W. Thompson. *Welding Journal,* Vol. 29, Mar. 1932, pages 77-79; discussion, Apr. 1932, pages 109-111.

Paper read before the members of the Midlands Branch of the Institution of Welding Engineers (Birmingham) Jan. 15, 1932. The author classifies and describes the various types of stainless steels, giving general compositions and properties. The 18-8 composition is discussed somewhat in detail. Also includes information on preparation for welding, oxy-acetylene, atomic hydrogen and metallic arc welding and a discussion of weld decay. TEJ (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Commercial Corrosion Occurrences, Their Causes and Prevention. (Korrosionsbeispiele aus der Praxis, ihre Ursache und Vermeidung.) K. Mandl. *Korrosion und Metallschutz*, Vol. 8, Jan. 1932, page 15.

Al gaskets for wrought iron pipe flanges of NH_3-plants failed in service. Instead of a metallic jacket an asbestos one should be employed. The corrosion of Al coils of cooling systems is explained by the occurrence of potential differences, and the analogy to the failure of Fe condenser pipes is pointed out. Preventive means such as galvanizing, cathodic treatment of Fe and dense lacquer coatings are recommended. The corrosion of Pb-coated roofings due to SO_2 is ascribed to the formation of local elements. An intermediate layer of Sn is urged. The corrosion of cast iron parts of paper pulp pumps can be eliminated by employing V2A steel or acid proof bronze. EF (4)

Corrosion of Ship Plates. J. Montgomery & W. E. Lewis. *Iron & Coal Trades Review*, Vol. 124, Feb. 26, 1932, page 357.

As a result of observations over a considerable period of time the conclusion is drawn that the problem of corrosion on the external surface of merchant vessels is primarily connected with the condition of the surface in respect to the amount of mill scale still adhering to them before the paint is applied. The best method of maintaining steel structures free from corrosion is, therefore, the thorough cleaning of the surfaces, including the removal of mill scale, and efficient painting thereafter. Ha (4)

Types of Rust Formation. (Die Arten der Rostbildung.) G. Chaudron. *Oberflächentechnik*, Vol. 9, Apr. 19, 1932, pages 78-79.

Starting from the fact that rust is started by the corrosion of wet Fe the local elements which form on the metal surface in certain salt solutions are seen as the cause of the corrosion. The different physical and chemical conditions which promote or delay rust formation are briefly discussed and the chemical changes which lead to rust forming oxide are explained. The efficacy of protective coatings by preventing the formation of local elements is briefly discussed. Ha (4)

On the Passivity of Chromium. (Zur Passivität des Chroms.) W. J. Müller. *Zeitschrift für Elektrochemie*, Vol. 37, June 1931, pages 328-330.

The author replies to the discussion and criticism of his previous papers on the passivity of Cr, and comments on the conclusions reached by E. Müller and others. He maintains that the theory developed by him and Essen satisfactorily explains the behavior of different acids in the activation of passive Cr. Ha (4)

The Topo-Chemistry of Corrosion and Passivity. II. Investigation of the Primary Corrosion Effect on Soft Iron. (Zur Topochemie der Korrosion und Passivität. II. Untersuchung des Primäraktes der Korrosion und Weicheisen.) E. Pietsch, B. Grosse-Eggebrecht & W. Roman. (Technische Hochschule Berlin). *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 157, Dec. 1931, pages 363-368.

Corrosion tests were performed with Krupp's soft iron (0.05% C, 0.06% Si, 0.08% Mn, 0.01% P, 0.01% S). 2 sets of experiments were carried out in which material with the same grain size but different preliminary treatment was used: (a) one set was annealed in the γ range; (b) the other group of samples was strain-hardened and recrystallized below A_1. The solution media employed were as follows: (1) H_2O_2 of various concentrations and with and without additions of different acids; (2) boiled out distilled water; (3) 1.6% aqueous NaI solution; (4) ½ *N* acetic acid, 1 *N* butyric acid, 1 *N* valeric acid, i. e. aqueous solutions of acids with increasing number of C atoms; (5) 1/10 *N* HCl. The systematic tests with these solutions permit the conclusion that the primary effect of corrosion consists in the adsorption of the attacking medium on the grain borders or similar linear discontinuities (for instance pipes, scratches, border lines of metal), indifferent substance of high surface tension. The formation of rust and the passification is explained by quantum-mechanic considerations. All tests and the test results are reproduced in full. Ha+EF (4)

Experiences with High-Pressure Boiler Plants. Marguerre. *Engineering*, Vol. 132, Aug. 28, 1931, pages 267-271.

Same as article in *Power*, Vol. 74, Oct. 13, 1931, pages 542-543. AHE (4)

The Corrosion Committee, Water Section, of the DVGW. The Question of Corrosion. (Aus dem Ausschuss "Korrosionsfragen" der Abteilung Wasser des DVGW. Zur Korrosionsfrage.) Thiesing. *Das Gas- und Wasserfach*, Vol. 75, Apr. 2, 1932, pages 253-255.

A general discussion of the present status of work on corrosion done by the Committee. The author considers the various theories of corrosion, the causes, the effects on different metals, the effect of the composition of the water, and the effects of fatigue, working of metals, etc., on the corrosive attack. MAB (4)

Solubility Studies of Boiler Water. Frederick G. Straub. *Combustion*, Vol. 3, Apr. 1932, pages 12-16.

Over 2000 separate solubility tests have been made to determine solubility data at higher temperatures and pressures. This data is to be used in determining causes of scale formation and methods of prevention. Data were taken over a range of temperatures corresponding to pressures 150 to 1500 lbs. gage. This investigation was undertaken due to failure of water wall tube of a boiler operating at 700 lbs. pressure. Solubilities were made in a large number of steel bombs, under conditions of equilibrium, which took generally 6 to 10 hrs. to reach. Assuming possibility that equilibrium does not exist in all parts of a boiler and also perhaps factors other than solubility affect scale formation, final tests are being conducted in an actual operating boiler designed for pressures up to the critical. Thus far from the bomb solubility data it is indicated that soda-ash treatment, properly controlled, should prevent $CaSO_4$ scale at pressures up to 1500-2000 lbs. without causing high alkalinities and without disturbing recommended embrittlement ratios. Additional factors are discussed. DTR (4)

Effective Elimination of Corrosion in Hot Galvanizing Plant Pots. (Wirksame Vermeidung von Anfressungen der Kessel bei Feuerverzinkungsanlagen.) E. Schrieder. *Stahl und Eisen*, Vol. 52, May 12, 1932, pages 470-471.

According to H. Grubitsch's work published in *Stahl und Eisen*, Vol. 51, 1931, pages 1113-1116, Fe is practically not attacked by molten Zn up to 475° C. From 475° to 490° C. the solubility rises rapidly, and with further temperature rise, the solubility decreases, reaching a minimum at 520° C. and above this it starts increasing gradually. Explanation for pitting and corrosion lies in local excessive heating above 475° C. and the pits appear as circular funnel shapes of about 3 to 5 cm. diameter. For protection against this pitting a novel yet simple method was devised by which an air space was allowed for between fire brick or fireclay and pot wall. This air space permits holding the temperature below 475° C. and gives uniform heat radiation without local heating. DTR (4)

Cadmium and Zinc Plating as Corrosion Preventives. S. Wernick. *Metallurgist*, Sept. 1931, pages 143-144; Oct. 1931, pages 147-148.

An article based on a paper before the Electroplaters' and Depositors' Technical Society. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 216. VVK (4)

Rust-Proofing Processes. *Automobile Engineer*, Vol. 21, Nov. 1931, page 544.

2 anti-rust processes developed by the Pyrene Company, Ltd., Great West Road, Brentford, are known as Parkerizing and Bonderizing. The Parkerizing process converts the surface of the treated metal to an insoluble phosphate which, under ordinary atmospheric conditions, is impervious to rust. Bonderizing gives a non-metallic coating which acts as a key to the finish. Briefly describes each process. RHP (4)

Rust Protection by the Atrament Method. (Rostschutz durch das Atrament Verfahren.) *Stahlbautechnik*, Supplement to *Montanistische Rundschau*, Vol. 24, Mar. 16, 1932, pages 7-8.

The Atrament method is a new coating method against corrosion, developed by the German Dye Trust. By dipping iron parts in a solution of phosphorous salts of a certain concentration a dense layer of phosphate is deposited which is insoluble in water. In a 2½% solution of "Atramenthol" the process takes about ½ to 1 hr. at 98° to 100° C. GN (4)

Corrosion of Metal Articles in Storage. Influence of Alkaline Surface Films. W. E. Cooper. *Industrial & Engineering Chemistry*, Vol. 23, Sept. 1931, pages 999-1002.

It is shown how the presence of small amounts of alkali deposited as an apparent uniform layer on metal articles serves to increase their freedom from tarnishing and rusting when stored in warehouses. Also, by choosing the most protective alkaline deposit, and adjusting and maintaining storage conditions in a state of constant control, it is possible to store articles for very many years without loss of luster. It is suggested that many cases occur where articles are being dipped in grease for storing, whereas investigation might prove that suitable alkaline treatment and control of warehouse conditions would result in considerable saving of storage costs by utilizing a cheaper method. MEH (4)

Distribution Sub-Committee on Pipe Coatings and Corrosion. J. K. Crowell. *American Gas Journal*, Vol. 136, May 1932, page 48.

Report of sub-committee to Distribution Conference. The findings of the committee include: (1) The only practical means of reaching a satisfactory solution of the problem of the protection of underground piping from corrosion is painstaking and necessarily slow research by those who are in a position to give their entire time to the work. (2) The protective value of a coating depends primarily upon the nature of the coating and to a minor extent upon the soil. (3) When a coating fails, the pitting rate depends upon the soil. (4) Electrical conductance and pinhole tests are useful methods for determining the protective value of coatings. (5) Protective value of a coating is increased by increasing the thickness, within certain limits. (6) Mechanical distortion after application is the principal cause of bituminous coating failures. (7) Organic reinforcing materials are decomposed by bacteria and fungi in the soil and the extent of this action depends upon the nature of the soil and the amount of protection by the use of disinfectants or bitumens. (8) Thin coatings do not add enough to the life of the pipe to justify their use. (9) The corrosiveness of a soil cannot as yet be accurately determined by the use of any method. (10) Corrosiveness of a soil can be fairly accurately determined by the use of a combination of methods. CBJ (4)

Progress in Fighting Corrosion. (Fortschritte in der Korrosionsbekämpfung.) H. Hebberling. *Die Werkzeugmaschine*, Vol. 36, Mar. 15, 1932, page 89.

The article refers in particular to the progress made in protective coatings made of oil lacquers, paints, etc. GN (4)

Economy in Wider Use of Protective Coatings on Pipes. Wm. Thompson Smith. *Engineering News-Record*, Vol. 108, Apr. 21, 1932, pages 576-578.

The problem of deciding whether to give an underground pipe line a protective coating or not is complicated by the varying conditions encountered. The cost of coating an entire line is a considerable item, on the other hand if no coating is given the line, localized areas may corrode through in a short time and cause severe losses. Sections of ground where soil corrosion is markedly severe are termed "hot spots." The best warranted method of saving in protection costs is not by waiting for hot spots to develop before using any coating but by coating all known or suspected areas of corrosion and omitting coating in non-corrosive areas as determined by a thorough soil-corrosion survey. STRUCTURE OF METALS & ALLOYS (5)

The Influence of Third Metals upon the Constitution of the Brasses. IV. The Influence of Aluminum. (Der Einfluss von dritten Metallen auf die Konstitution der Messinglegierungen. IV. Der Einfluss von Aluminium.) O. Bauer & M. Hansen. *Zeitschrift für Metallkunde,* Vol. 24, Jan. 1932, pages 1-6.

The ternary system Cu-Zn-Al was investigated in the composition range 100 — 50% Cu and 0 — 10% Al, by thermal and micrographic studies of alloys with constant Al content at 1, 2, 4, 6, 8, and 10% respectively. The solidification of these ternary alloys is quite analogous to that of the respective binary alloys. Within a certain range of composition the peritectic reactions α + melt $\rightarrow$ β and β + melt $\rightarrow$ γ take place. The peritectic temperatures in the Cu-Zn system are lowered by the addition of Al. Three one-phase fields obtain in the ternary system: α, β, and γ; 3 two-phase fields: $(\alpha + \beta)$, $(\beta + \gamma)$, and $(\alpha + \gamma)$; and one three-phase field: $(\alpha + \beta + \gamma)$. The limit of the saturated phase in the Cu-Zn system is displaced to 72.5% Cu by the addition of 3.5% Al; the limit of the saturated field in the Cu-Zn system is displaced to 65.5% Cu by the addition of 4.25% Al. Al-contents greater than 3.5 — 4.25% induce the formation of the brittle γ-crystals. The influence of Al upon the color and Brinell hardness is noted. It is concluded that the usefulness of brasses modified by the addition of Al has been under-estimated. The paper includes a critical study of previous work in the system. RFM (5)

Metallography & Macrography (5a)

Solidification Temperatures of Cast Bronze and Red Brass. (Estarrungstemperaturen der Gussbronzen und Rotgusslegierungen.) O. Bauer & M. Hansen. *Zeitschrift für Metallkunde,* Vol. 24, Mar. 1932, page 63.

The following data are given: alloy with Cu 90%, Sn 10%: beginning of freezing 1009° C.; alloy with Cu 86%, Sn 14%: beginning of freezing 971° C., peritectic reaction (α + melt $\rightarrow$ β) and end of freezing 793° C.; alloy with Cu 80%, Sn 20%: beginning of freezing 898° C., peritectic reaction (α + melt $\rightarrow$ β) and end of freezing 797° C.; alloy with Cu 79%, Sn 8%, Pb 13%: beginning of freezing 959° G., first separation of Pb 891° C., reaction α + liq.Cu $\rightarrow$ β + liq.Pb 764° C., end of freezing (crystallization of Pb-rich phase) 314° C.; alloy with Cu 86%, Sn 10%, Zn 4%: beginning of freezing 1000° C., reaction liq.Cu $\rightarrow$ β + liq.Pb 788° C., reaction α + liq.Cu $\rightarrow$ β + liq.Pb; alloy with Cu 85%, Sn 9%, Zn 6%: beginning of freezing 994° C., peritectic reaction (α + melt $\rightarrow$ β) 787° C.; alloy with Cu 85%, Sn 5%, Zn + Pb 10%: beginning of freezing 1016° C., reaction liq.Cu $\rightarrow$ α + liq.Pb 887° C. RFM (5a)

Large Grain Size in Aluminium Wire. Clement Blazey. *Chemical Engineering & Mining Review,* Vol. 24, Mar. 5, 1932, pages 193-196.

Al rivets are influenced by grain size. Brinell impressions of good rivets are circular in outline while those of bad rivets are irregular in shape. A single crystal of metal does not take a spherical impression. When the crystal grain is larger than the ball impression, the directional properties of the grain will influence to a noticeable degree the shape of the impression. It was impossible to produce even-headed rivets from coarse-grained metal. To produce coarse-grained metal, a critical amount of cold work, followed by a critical annealing temperature, is necessary. WHB (5a)

The Miscibility Gaps in the Systems Lead-Copper and Lead-Copper-Tin. (Die Mischungslücke in den Systemen Blei-Kupfer und Blei-Kupfer-Zinn.) S. Briesemeister. *Zeitschrift für Metallkunde,* Vol. 23, Aug. 1931, pages 225-230.

The methods for the determination of the solubility curve between the 2 liquid layers in metals showing a miscibility gap in the liquid state are reviewed, and that consisting in removing samples from the 2 layers with subsequent chemical analysis indicated as the most trustworthy. Using this method the critical point (maximum temperature and accompanying composition) in the Pb-Cu system was found to be at 1000° C. and 65% Pb; the composition range of immiscibility at the monotectic temperature was found to extend from 60 or 61% to 7.5% Cu. The first effect of adding Sn to the Pb-Cu system is to widen the miscibility gap. Solubility isotherms are given for the temperatures 835°, 955°, 1005°, 1060° and 1110° C. The effect of Sn in widening the miscibility gap is explained by the presence of Cu_3Sn molecular complexes in the molten alloy. These complexes on increasing temperature dissociate and the solubility accordingly increases. The critical point is determined to be at 1130-1140° C. and at the composition 35% Cu, 50% Pb, 15% Sn. The importance of these results in the manufacture of Pb-bearing bronzes is discussed. RFM (5a)

Regeneration of the Recrystallization Ability by Retro-Formation. (Rückbildung der Rekristallisationsfähigkeit durch Rückformung.) P. Beck & M. Polanyi. *Die Naturwissenschaften,* Vol. 19, June 5, 1931, pages 505-506.

Studies upon the Systems Ag-Sb-Zn, Ag-Cd-Sb and Ag-Cu-Sb. (Zur Klärung der Systeme Ag-Sb-Zn, Ag-Cd-Sb und Ag-Cu-Sb.) W. Guertler & W. Rosenthal. *Zeitschrift für Metallkunde,* Vol. 24, Jan. 1932, pages 7-10; Feb. 1932, pages 30-34.

The constitution of the systems Ag-Sb-Zn, Ag-Cd-Sb, and Ag-Cu-Sb was studied metallographically and by the use of Guertler's "Klarkreuz" method, chiefly because of the interest in these alloys in the development of new Ag alloys. The results are expressed in a series of constitutional diagrams. Difficulties in the application of the "Klarkreuz" method, the etching characteristics of the alloys studied and the technical use of the alloys are discussed. RFM (5a)

The Iron-Beryllium System. R. H. Harrington. *Metals & Alloys,* Vol. 3, Feb. 1932, pages 43-45.

The author shows 11 micrographs obtained from the case on the surface of cold rolled steel subjected to a "beryllizing" treatment in powdered beryllium at 1000° C. to check qualitatively certain discrepancies in the published work on the Fe-Be diagram. The results appear to agree with the diagram of Oesterheld with the exception of the extention of the eutectoid line to very low beryllium. The diagram is reproduced. WLC (5a)

The Austenite-Pearlite Inversion. H. C. H. Carpenter & J. M. Robertson. (Royal School of Mines). *Iron & Steel Institute, Advance Copy* No. 7, May 1932, 20 pages.

The pearlite transformation was studied by examining microstructures of several C steels that had been subjected to special heat treatments. Steels containing 0.43, 0.73 and 0.81% C were cooled in such a manner to produce an appreciable temperature gradient in the samples and quenching when pearlite had formed in part of the sample. Several cooling rates were used. Specimens were also non-uniformly heated to the transition range and cooled rapidly. It is pointed out that in ordinary steels the pearlitic transformation occurs over a range of temperatures because of the impurities in the steel. Even with slow cooling of pure Fe-C alloys the transformation occurs over a range, but if the steel is held at or below a certain temperature the change proceeds to completion. Possible mechanics for the formation of ferritic and cementitic lamallae are discussed. The microstructures showed that the ferrite and cementite form simultaneously, and a given particle of pearlite consists of plates advancing edgewise into the austenite. The dependence of the form of the pearlite on the C content and rate of cooling is discussed. 10 references. JLG (5a)

Black Magnetic Rouge Polishes Rapidly and Without Flow. W. J. Crook & W. R. Philbrook. *Metal Progress,* Vol. 21, May 1932, pages 72-74.

Black rouge, 99% Fe_3O_4, has been found to be superior to either magnesia or alumina as a final polishing material for preparing specimens for microphotography. WLC (5a)

Thermodynamic Investigations of the System Iron-Carbon-Oxygen. II. (Thermodynamische Untersuchungen zum System Eisen-Kohlenstoff-Sauerstoff. II.) H. Duenwald & C. Wagner. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 205, Apr. 8, 1932, pages 205-208.

Discrepancies in the measurements and calculations of the equilibrium diagram in a previous investigation of Krings are discussed. Diffusion constants are in reality no constants of the material but depend on the structure of it and change with structural changes. Ha (5a)

On the Supposed Allotropy of Lead. W. Eda. *Kinzoku no Kenkyu,* Mar. 1932, pages 125-130 (In Japanese); *Science Reports Tohoku Imperial University,* Vol. 20, 1931, pages 715-725 (In English).

The existence of an allotropy of Pb at 200° C. was suggested by F. Hargreaves. But as he only made a hardness test on quenched Pb, the author repeated the investigation by means of hardness tests (both at room temperature and at high temperature), electric resistance measurements, differential thermal analyses and X-ray investigations. In the case of single crystals of Pb no abrupt change of hardness was found. Also no abrupt change was observed in electric resistance or on differential thermal analysis. Moreover, no evidence of allotropy was detected by X-ray analysis. Hence the author concluded that lead has no allotropy in the temperature range of 20°-300° C. KT (5a)

The Reactivity of Metal Alloys and Their Dependence on Fusion Phenomena or Transformations in Solid State. (Die Reaktionsfähigkeit der Metallegierungen und ihre Abhängigkeit von Schmelzerscheinungen oder Umwandlungen im festen Zustand.) J. Arvid Hedvall & F. Ilander. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 203, Jan. 26, 1932, pages 373-389.

The reactions between metals when adding basic oxides in the presence of oxygen take the same course as found formerly for additions of sulphides, phosphides, carbides and silicides, and there is no difference whether the metals are solid or in fusion. It could be stated that Cu-Sn alloys in various compositions in the presence of oxygen can attack crucible material containing Ca or Si even at temperatures as low as 400° C. Ha (5a)

The Behaviour of Single Crystals of Bismuth Subjected to Alternating Torsional Stresses. H. J. Gough & H. L. Cox. *Institute of Metals, Advance Copy* No. 592, Mar. 1932, 21 pages.

2 single crystals of Bi were subjected to alternating torsional stresses and the mechanism of deformation studied. In the early stages of the tests numerous bands were formed parallel to the twinning planes. No slip bands were observed at any stage. Values of normal and shear stress for various planes in the crystals were calculated. The mechanism of deformation is discussed at length. 10 references. JLG (5a)

The Recrystallization of Aluminum and Some Refinable Aluminum Alloys. (Ueber die Rekristallisation von Aluminium und einigen vergütbaren Aluminiumlegierungen.) H. Haneman & R. Vogel. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 4, Jan.-Feb. 1932, pages 3-23.

The investigations made on the recrystallization and the development of the recrystallization diagram, that is the diagram showing the grain size of the recrystallized metal for the selected recrystallization time as function of the degree of deformation and of the temperature at which recrystallization takes place, are reviewed and diagrams of more recent tests are discussed. In general, the recrystallization temperature of pure Al is increased by the alloying components. Small amounts of Mn and Si reduce the recrystallization ability. The velocity of deformation exerts a great influence on the formation of the recrystallization structure. The hypothesis of Tammann was corroborated, that is, that just for Al the effect of the intermediary substance is of greatest importance for the recrystallization. These recrystallization diagrams are, however, valid only for material that has been thoroughly worked and has a very fine grain; that means where the intermediary substance is in the most finely distributed form in the material. For the practical forging of refinable Al alloys the following directions are given for the prevention of coarse grain: The range of critical elongation lies between 5 and 20%; forging should therefore be done at rather high temperature. To avoid critical deformation, it should be effected with few but strong blows; the same degree of deformation obtained by many light blows results in coarser grain. When deforming under the press, small velocities of deformation must be avoided as they cause a coarse grain. Ha (5a)

Testing the Material in Hollow Cylinders with a Cinematograph. (Materialprüfung von Hohlzylindern auf kinematographischen Wege.) *Maschinenkonstrukteur - Betriebstechnik,* Vol. 65, Feb. 10, 1932, pages 14-17.

A new method for testing inaccessible parts of the walls in long hollow tubes is described. The X-ray is used. MAB (5b)

Internal Stresses and Their Roentgenographic Proof. (Innere Spannungen und ihr Roentgenographischer Nachweis.) Fritz Regler. *Mitteilungen der technischen Versuchsamtes in Wien,* Vol. 20, Nos. 1-4, 1931, pages 43-58.

Structure diagrams taken by the Laué method do not always give a real picture of the inner condition of the crystals as the very thin sample prepared for the Laué test mostly affords an opportunity for the equalization of inner stresses as the sharp photographs show. Stresses would give a certain lack of clearness. The author developed a method which permits taking reflection diagrams of its fine structure with X-rays directly on the work piece; this method has the further advantage that it does not injure the material and the crystal lattice has no opportunity to change its state because it is not machined. The diagram is taken by reflecting a parallel beam of X-rays on the piece to be examined. The difference between the diagrams of materials with inner stresses due to the treatment of the material and stresses due to outer influences as tension, pressure, etc., are explained and illustrated. The methods of taking the diagrams and evaluating them is described in detail. The method has been developed so that now also quantitative measurements of stresses especially in the elastic range can be made in the shop. Ha (5b)

Atomic Physics and Metallurgy. (Atomphysik und Metallkunde.) E. Piwowarsky. *Mitteilungen aus dem Giesserei-Institut der technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 7 pages.

Quantitative X-Ray Analysis. Henry Terrey & E. G. V. Barrett. *Journal of Physical Chemistry,* Vol. 35, Apr. 1931, page 1156.

In general the alloy to be analyzed is made the anticathode in an X-ray tube and the relative intensities of the characteristic radiation of the different atomic species present are determined. It is thought that the anomalies in previous results were due to absorption of the characteristic radiation of one element by another element present in the anticathode. It is shown that for elements near each other in the periodic system the relative intensities of two similar characteristic lines is proportional to the atomic concentration of each. The relative intensities of the $K\alpha_{2\cdot1}$ lines were measured for a series of Cu-Zn, and a series of Cu-Ag alloys. These two series of alloys were selected since Cu absorbs the $K\alpha_1$ line of Ag but not that of Zn. To avoid errors in estimating blackening of the photographic film an ionization method was used for intensity determination; also a photographic method involving an Al absorption wedge was used in which lengths instead of blackness could be measured. In the Cu-Ag alloys the following relation between intensities and concentration was found to hold:

$$\frac{I_{Ag}}{I_{Cu}} = M \frac{C}{C_{Ag} + C_{Cu}}$$

where M is a proportionality constant. The Ag radiation suffers partial absorption in the Cu and gives rise thereby to secondary Cu radiation, thus diminishing the Ag radiation and augmenting the Cu. A linear relationship between relative intensity and atomic concentration was found to hold for the Cu-Zn alloys. WHK (5b)

Dispersion of Aluminum in the Range of 1.1 - 2.3 A.U. (Dispersion von Aluminium im Gebiet von 1.1 - 2.3 A.E.) H. Steps. *Die Naturwissenschaften,* Vol. 19, July 10, 1931, page 617.

By a photometric method the dispersion of Al was investigated and found to be in accordance with the Drude-Lorentz equation. EF (5b)

X-Ray Analysis of the Gold-Tin Alloys. (Roentgenanalyse der Gold-Zinn-Legierungen.) Sten Stenbeck & A. Westgen. *Zeitschrift für physikalische Chemie,* Vol. 14, Sec. B, Sept. 1931, pages 91-96.

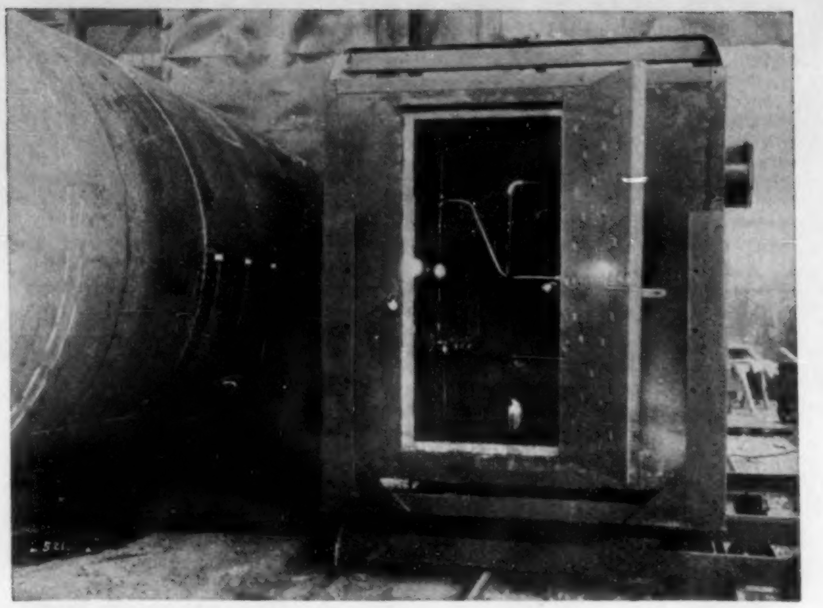
Besides the known compounds AuSn, $AuSn_2$ and $AuSn_4$, another fourth intermediary phase exists in the range from 12 to 16 atomic % Sn. The lattice structures of the compounds were examined by X-rays; they seem to be very complicated as they show very many lines. Ha (5b)

X-Ray Scattering and Atomic Structure. E. O. Wollan. *Reviews of Modern Physics,* Vol. 4, Apr. 1932, pages 205-258.

The theory of the reflection of X-rays from crystals is reviewed, as well as scattering of X-rays by gases and diffuse scattering of X-rays by crystals. A comparison of various methods of obtaining the atomic structure factor is also included. A bibliography of 96 references is appended. WAT (5b)

Radiographic Picture of a Welded Seam. (Röntgenuntersuchung eines Schweissmusters.) *Zeitschrift für Schweisstechnik,* Vol. 21, Aug. 1931, page 187.

Disregarding a few minor discontinuities due to slag inclusions or blowholes, a very perfect and uniform gas-welded seam was secured as disclosed by the X-ray photograph. EF (5b)



Testing Methods for Welded Tube Joints. (Prüfungsverfahren geschweisster Rohrverbindungen.) *Die Röhrenindustrie,* Vol. 24, May 24, 1931, pages 123-124.

Visual examination, X-ray inspection by radiographic photography and examination on a fluorescence screen, electromagnetic tests (tests in the Technische Hochschule Braunschweig and in the Kaiser Wilhelm Institut für Eisenforschung), etching methods (Dampfkesselüberwachungsverein) Brinell hardness tests, bending, tensile, microscopic and various kinds of pressure tests are reviewed. EF (6)

Attainment of a Constant Bend in Deflection Test Work. (Erreichung einer stetigen Krümmung bei der technologischen Biegeprobe.) *Stahl und Eisen,* Vol. 52, Apr. 28, 1932, pages 409-411.

Illustrations of old and new methods of making bends of test samples. The new die or stamp shape produces a uniform, even and constant bend in deflection samples. Curves are given for % elongation by old and new ways for angles up to 170°. DTR (6)

The Testing of Iron Castings. A. W. Walker. *Foundry Trade Journal,* Vol. 46, Apr. 14, 1932, pages 233-235.

Deals with the factors influencing the strength of cast Fe and then passes on to discuss the value of the transverse, tensile and Brinell hardness tests in determining mechanical characteristics of this material. Some reference is made to modern methods of producing special cast irons. OWE (6)

Examination of Deep Drawing Quality of Sheet Metal. (Untersuchungen über die Prüfung der Tiefziehfähigkeit von Feinblechen). Fritz Eisenkolb. *Stahl und Eisen,* Vol. 52, Apr. 14, 1932, pages 357-364.

Report 178 of Committee on Materials of Verein deutscher Eisenhüttenleute. Includes discussion. According to the author a sheet should be judged by 2 properties: (1) by number of draws necessary to obtain desired shape; (2) maximum amount of drawing without having to anneal. Effect of irregularities in chemical composition was shown by Erichsen tests on 1000 × 2000 × 1 mm sheets. For composition 0.058% C, 0.32% Mn, 0.018% P, 0.017% S, and original Erichsen 11.3, after 4th draw final Erichsen was 6.9; similarly for composition 0.072% C, 0.32% Mn, 0.028% P, 0.026% S, original Erichsen 11.2, after 4th draw final Erichsen 6.2. Purer material gives better deep drawing quality. Effect of annealing, that is, effect of crystal structure is shown by following:

Structure	Erichsen Original	Erichsen After 4th draw
1. Banded cementite	11.3	6.7
2. Heavily banded pearlite	11.4	8.1
3. Banded pearlite	12.1	8.2
4. Granular cementite	11.8	8.2

Slight advantage in deep drawing quality is observed when the spinning or stamping is perpendicular to the direction of rolling. With an original Erichsen 10.8, on 18 test sheets, on material drawn parallel to direction of rolling, the average final Erichsen was 6.8; perpendicular to rolling direction, 7.8. With the latter material T.S. and elastic limit were higher, % elongation and Amsler deflection No. were less. When several spins or stamps are to be made, test data showed much better results by making successive draws as soon as possible, while material is still warm. This confirms the practical method of spinners and stampers. Average values of all physical properties for 10 classes of sheets, rolled, drawn and annealed in various ways are tabulated in order to show that various test methods do not always agree and that a more general method should be developed. In order that sheets may have good uniform deep drawing quality they should be of uniform gage, smooth throughout entire surface, without scratches, oxide inclusions, or other defects and uniform in crystal structure. DTR (6)

Sockets of Low-Melting Alloy Best for Wire-Rope Test Samples. D. H. Corey & E. T. Cope. *Engineering News-Record,* Vol. 108, May 5, 1932, page 652.

Samples of wire rope socketed with spelter broke near the sockets and gave low tensile strengths. From the location of the breaks it was thought that the skin hardness, resulting from cold drawing of the wire in manufacture, had been decreased at the temperature at which the spelter was poured, about 1000° F. Alloys of low melting point were investigated. When samples were socketed with 83-7-10 Pb-Sn-Sb alloy of a pouring temperature of 500-650° F., better tensile strengths were obtained. The location of the failures were such that it appeared that the full strength of the rope was being developed. CBJ (6)

Magnetostriction of Ferromagnetic Materials (Magnetostriktion ferromagnetischer Stoffe). G. Dietsch. *Zeitschrift für technische Physik,* Vol. 12, July 1931, pages 380-389.

A testing method is described which, in comparison with the testing equipment formerly used, yielded an increase in sensitivity of the "balance method" amounting to 2 decimals. This is achieved by the utilization of shorter wave lengths (70 m.), smaller distances of the condenser plates (0.02-0.003 cm.) and by the application of relatively long samples (28.5 cm.). In the case of electrolytic Ni, remarkable hysteresis phenomena were observed, which sometimes yielded positive values never measured before. An influence is exerted by the pre-treatment. A second set of tests refer to Be-Ni alloys. In those samples submitted to an age-hardening treatment, a decrease in magnetostriction was observed, due to the disintegration of the solid solution. While no material changes were noticed with Be-permalloy alloys (0.5 and 1% Be), the stainless steel used (0.17% C, 1.8% Ni, 14.2% Cr) exhibited considerably larger changes of the length in the magnetic field in comparison with electrolytic iron. The influence of preceding mechanical stress exceeding the limit of elasticity generally results in a decrease in magnetostriction. An initial increase, however, was observed in electrolytic Fe and in age-hardening Be-Ni starting at a field density of about 100 Gauss. Slight elongations of 1-2% cause more pronounced changes in magnetostriction than large degrees of elongation. A dynamic pre-treatment did not exert any influence upon the course of the striction-curves. EF (6)

Effect of Size of Test Bars on Transverse Test Results of Cast Iron. (Einfluss der Probestabmasse auf die Ergebnisse des Biegeversuchs bei Gusseisen.) Gustav Meyersberg. *Archiv für Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 513-517.

A study was made of the effect of diameter and of ratio of test bar length to diameter on transverse test results of unmachined cast Fe rods. Deflection (f) and strain number (Z_f) decrease with decreasing d and ls/d ratio; modulus of rupture (σ_B) increases. Z_f and f may be computed from Hooke's law; the effect of structural changes of the material through varying cooling conditions is deciding factor in the case of σ_B. Any additional variations from Hooke's law may be seen from curves plotted from test data. Equations were derived giving relations between ls/d = λ and d, for f, Z_f and σ_B. Equation $f = \frac{\sigma_B}{6E} : \lambda^2 d$ was also derived where E = modulus of elasticity. Average deviations of individual values from group average values for variations in diameter are given. DTR (6)

Methods of Testing Gray Iron Bars and Castings. (I Metodi di prova della ghisa gregia e il collauda dei getti). I. Musatti & G. Calbiani. *La Metallurgia Italiana,* Vol. 24, Apr. 1932, pages 267-291.

A very complete survey of the testing methods and test bars in use for gray iron throughout the world, with suggestions for the development of Italian standards, after a coöperative study which is outlined. It is emphasized that the bars adopted should, as far as is feasible, correspond to the standards of other countries so that published data will be directly comparable. Comparisons are suggested on (a) transverse bars 30 mm. diam. tested on 300, 455 and 600 mm. centers and on those of 40 and 55 mm. diam., on 455 mm. centers. (b) tensile bars, (c) Frémont shear tests, (d) compression on 16 × 16 mm. and 20 × 20 mm. specimens, (d) Brinell and (e) a small Frémont transverse test. It is suggested that test bars should be cast of such cross section as to approximate that of the castings into which the iron is to be poured, and that the Brinell relationship of these bars and of the castings themselves be used to show how nearly the bar represents the casting. The tensile test is not considered very suitable for routine testing because of difficulties in accurate testing of non-ductile material. The Frémont test is considered more practical. 79 references. The Resistance to Wear of Carbon Steels. Samuel Rosenberg. *Transactions American Society for Steel Treating,* Vol. 19, Jan. 1932, pages 247-270.

Includes discussion. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 37. WLC (6)

Mechanical Properties of Gray Iron Castings. (Caractérisation des propriétés mécaniques des pièces moulées en fonte grise). Albert Portevin. *Revue de Métallurgie,* Vol. 29, Feb. 1932, pages 61-73.

A critical survey of the methods used for testing cast iron castings. 61 references. JDG (6)

Methods of Testing Cast Iron. The Zürich Discussion. J. G. Pearce. *Bulletin British Cast Iron Research Association,* Vol. 3, Apr. 1932, pages 88-90.

The conclusions drawn from the discussions summed up by the president are briefly that in the opinion of the great majority the use of a separately cast test-bar, to be tested in tension and bending, is regarded as satisfactory and sufficient for the majority of industrial purposes; but for the exploration of the properties of various parts of castings and for the study of variations from one casting to another and for the investigation of failures of castings in service, the small test piece cut from the casting itself should be used. Ha (6)

The Shape of the Tensile Test Bar for Cast Iron. J. G. Pearce. *Bulletin British Cast Iron Research Association,* Vol. 3, Apr. 1932, pages 86-88.

The standard tensile test bars in Great Britain, America and Germany are described and compared and a series of systematic tests with a material of a definite composition were made to find the influence of the shape of the samples on the strength. The conclusions from the tests are that there is no regular variation in strength with grip length nor with gage length. Irrespective of these 2 lengths, the tensile strength was constant to within ± 5%, the variations being very likely due to the material itself. Ha (6)

Magnetostriction of Metals. J. S. Rankin. *Iron & Coal Trades Review,* Vol. 124, Mar. 18, 1932, page 472.

Tests are described for finding the effect of successive draws of wires on magnetostriction. The formerly assumed explanation of the decrease in magnetostriction with drawing seems not to be corroborated; at least, it can not be attributed to inner stresses. An exact explanation can not yet be given. Ha (6)

The Testing of Castings. Walter Rosenhain. *Institute of Metals, Advance Copy* No. 601, Mar. 1932, 13 pages.

Opening address for a general discussion held at the annual meeting of the Institute of Metals, Mar. 10, 1932. A general discussion of sampling and testing methods with particular reference to the testing of cast iron. Reasons are given for favoring a separately cast test bar. Includes an appendix summarizing the conclusions reached at the Zürich meeting of the New International Association for Testing Materials regarding the testing of cast iron. The majority of those at the meeting favored a separately cast test bar. JLG (6)

The Wear of Cast-Iron Brake Blocks (Beiträge zur Abnutzung gusseiserner Bremsklötze). E. Scharffenberg. *Die Giesserei,* Vol. 19, Apr. 15, 1932, pages 145-149.

On the basis of wear tests curves are derived which show the wear of material in mg./kg./hr. as a function of the content of Si (from 0.9 to 2.3%), of Mn (from 0.4 to 2.2%), of P (from 0.3 to 0.9%), and of S (from 0.04 to 0.21%). The tests showed also that the temperature occurring during the wearing does not give an indication of the resistance to wear, but Brinell hardness and wear showed a certain relation. P and S retard wear while Si increases wear at contents of more than 1.7% Mn shows an optimum at 1.4%. Ha (6)

ELECTRO-CHEMISTRY (7)

Investigations of the Temperature Dependency of Copper and Silver Single Potentials. (Untersuchungen über die Temperaturabhängigkeit von Kupfer und Silbersalzen Einzelpotentialen.) R. BURIAN. *Zeitschrift für Elektrochemie,* Vol. 37, May 1931, pages 238-251.

To determine the temperature coefficient of solutions the activity of which depends upon their temperature (entropy changes of the ionization process), careful measurements on Cu electrodes against $CuSO_4$ solutions were undertaken. Measurements with *M* $CuS0_4$ without additions of acid showed a fall of potential, π, above 40° C., and a precipitate appeared on the electrode; when 0.01 *N* H_2SO_4 was added, the temperature coefficient up to 60° C. was positive and nearly constant; above 60° the increase in potential was larger; no precipitate appeared on the electrode; on cooling, metallic Cu precipitated from solution. The average value of $d\pi/dT$ for Cu *M* $CuSO_4$, 0.01 *N* $H_2SO_4 = 7.9 \times 10^{-4}$ v. between 20° and 60° C.; for 0.1 *M* $CuSO_4$ and 0.001 *N* H_2SO_4 between 25° and 60° C. the coefficient is 7.2×10^{-4} v.; for 0.01 *M* $CuSO_4$ in the latter case a value of 4.3×10^{-4} was obtained. Cooling after heating the electrode produces a lower e.m.f. than the original corresponding to the same temperature on account of precipitation of basic salts on the electrode. In general the experimental results agree well with calculated. For Ag | n *M* $AgNO_3$ the following results were obtained: 3.162 *M* $AgNO_3$ between 18° and 45° C. gives a coefficient of -0.000148 V. per degree; 0.3162 *M* $AgNO_3$ between 18° and 55° C., 0.00030 V. per degree; 0.1 *M* $AgNO_3$, 12°-65° C., -0.00042 V. per degree; 0.01 *M* $AgNO_3$, 17-60° C., -0.00065 v. per degree. The temperature coefficient for the normal calomel electrode was redetermined in this work; between 20° and 48° C. it averages 0.00057. Ha (7)

Temperature Measurements on Electrodes in Motion. V, VI. (Temperaturmessung an arbeitenden Elektroden. V, VI.) B. BRUZS. *Zeitschrift für physikalische Chemie,* Sect. A, Vol. 155, Aug. 1931, pages 392-402; Oct. 1931, pages 279-290.

A dynamic calorimeter yielding a sensitivity in temperature indication of 1.8×10^{-6} degree/mm. and a thermal (Peltier) sensitivity of 4.5×10^{-7} watt/cm.² is described. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 257. EF (7)

The Buffer Action of Tungstate Solutions. (Ueber die Pufferwirkung von Wolframatlösungen.) WALTER QUIST & ALMAR LUND. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 205, Apr. 8, 1932, pages 87-94.

By adding a dilute acid to certain tungstate solutions aggregation reactions take place in which new, tungsten-rich anions are formed. The relation of the pH value to the concentration of sodium tungstate solutions is determined and results tabulated. Ha (7)

Electroplating (7a)

Rapid Nickel Plating. C. H. ELDRIDGE. *Monthly Review, American Electroplaters Society,* Vol. 19, Mar. 1932, pages 21-29.

Paper before Detroit Branch Meeting, Feb. 1932. The author gives a comparison of present-day practice in rapid Ni plating in the U.S.A. and in Europe. French platers use the following formula.

$NiSO_4 7H_2O$	53-67 oz./gal.
$NiCl_2 6H_2O$	3 oz./gal.
H_3BO_3	3 oz./gal.
$Ni(NO_3)_2$, 20% solution	3-4 cc./gal.
pH	4.8-5.7
Temperature	45-55° C.
Current density	75-110 amp./ft.²

Before nickel plating, steel parts are anodically treated in 53° Be. H_2SO_4 for 10-30 sec. at 150 amp./ft.². The Ni deposit is usually 0.0008 to 0.001" thick. Cu under-coating is not used. English practice uses a formula similar to the French practice. Current density used is lower. Bath is agitated by compressed air and filtered continuously. Anodes are bagged. Anodic cleaning of steel parts uses a strong H_2SO_4 containing 3 oz./gal. $K_2Cr_2O_7$. In American practice, there are 2 types of baths, the high and the low pH baths. The high pH bath is not unlike those used in France and England. Solution is continuously filtered. Current density used is such as to give 0.001" in 10 min. The low pH bath has lower Ni content:

$NiSO_4 7H_2O$	33 oz./gal.
$NiCl_2 6H_2O$	6 oz./gal.
H_3BO_3	3-4 oz./gal.
pH	2.5
Temperature	150° F.
Current density	90-100 amp./ft.²

The Electrodeposition of Tin from Solutions of Sodium Stannate. D. T. EWING & ALF. CLARK. *Michigan Engineering Experiment Station Bulletin* No. 43, Vol. 7, Feb. 1932, pages 3-14.

The advantages of Sn as a corrosion resisting material are pointed out and the various processes for its electrolytic deposition are briefly reviewed. The methods with basic solutions generally use sodium stannate; the paper investigates the influence of concentration, temperature, current densities and alkalinity, on the structure of the deposited Sn. With Sn anodes, a black insoluble substance is formed which can be prevented almost entirely by addition of NaOH and heating to 60° C. Fe anodes do not form this black substance, but on continued use a white product is formed which can also be prevented by NaOH. Sn plates formed at higher temperatures are more porous than those formed at room temperature; they also have a lighter color. The best current density is 1 amp./cm.² The presence of metallic salts in the solution has no marked effect on the character of the Sn deposit. The best concentration of the bath is 140 g. of sodium stannate per liter. Ha (7a)

Cause of Adherence of Electrodeposits. G. DUBPERNELL. *Monthly Review, American Electroplaters Society,* Vol. 19, Mar. 1932, pages 9-17.

Paper before Detroit Branch Meeting, Jan. 8, 1932. The author reviews various theories since 1873. Two of them are most important, (1) deposited metal and base metal are held together by molecular attraction (2) the deposited metal is interlocked into the base metal which is slightly etched before plating. For metals such as Ni, Cr, and Al which tend to become passive, a cathodic treatment in 10-20% HCl will improve the adherence between these metals and the deposited coating. LCP (7a)

Gold Solutions for Production Work. J. L. MERIGOLD. *Monthly Review, American Electroplaters Society,* Vol. 19, May 1932, pages 26-32.

Paper before Los Angeles Branch Annual Meeting, Mar. 12, 1932. 20 formulas for gold plating including immersion plating, salt-water plating, electroplating, combination of salt-water and electroplating, 14 K gold, green gold, rose gold, purple gold, brown gold, pink gold, gray gold, red gold and white gold. LCP (7a)

Deposit Chromium on Electric Appliances. F. A. MAURER. *Monthly Review, American Electroplaters Society,* May 1932, pages 21-26.

Paper before Los Angeles Branch Annual Meeting, Mar. 12, 1932. Operating details for applying a Cu-Ni-Cr coating on steel and cast-iron parts of electric flatiron are given. All parts have a rust-proofness equivalent to 8 hours salt spray test. LCP (7a)

Progress Report on Exposure Tests of Plated Coatings. P. C. STRAUSSER. *Monthly Review, American Electroplaters Society,* Vol. 19, Feb. 1932, pages 15-26; *Metal Industry,* N. Y., Vol. 30, Apr. 1932, pages 150-152.

Includes discussion. Paper before Rochester Convention, July 1931. The report describes preparations at Bureau of Standards for corrosion tests to be made on steel specimens variously plated with Ni, Cr, Zn, Cd and Cd-Zn alloy. The work is done under the joint auspices of American Electroplaters Society and American Society of Testing Materials. PRK + LCP (7a)

Anodic Phenomena in Cadmium Plating Solutions. G. SODERBERG. *Monthly Review, American Electroplaters Society,* Vol. 19, Feb. 1932, pages 9-15.

Paper before Rochester Convention, July 1931. Cadmium anodes in a cyanide cadmium plating bath become polarized at 20-30 amp./ft.², depending on free NaCN content. Anode current density remains practically constant, when anode polarization is increased from 0.2 to 3 volts. With Fe anodes, the anode polarization has a nearly fixed value of 1.9-2 volts. With a combination of Cd and Fe anodes, the Fe anodes do not function until Cd anodes become polarized, i.e., over 20 amp./ft.² Voltage necessary to discharge O at anodes is much higher than what is normal with Cd plating, using either Cd or Fe anodes. Carbonate content in Cd plating bath is increased by elevated temperature and by using Fe anodes, but not by using a combination of Cd and Fe anodes. LCP (7a)

Electrometallurgy (7b)

Electrochemistry and Electrometallurgy. Electrolytic Processes. H. J. T. ELLINGHAM. **Electrothermal Processes.** H. MOORE. *Journal Institution of Electrical Engineers,* Vol. 69, Jan. 1931, pages 185-192.

The paper presents a summary of the present state and recent developments of electrolytic processes as they are employed for the direct production of a metal from one of its compounds (oxide, sulphate, etc.) which has been separated or formed from the ore by other metallurgical operations (concentration, roasting, leaching, etc.); or or the separation of 2 metals from an alloy produced by furnace reduction; or for refining a crude metal obtained by furnace reduction. The processes are discussed at length with reference to the methods used in the extraction of Ni by the International Nickel Co. and the refining of Cu by several American companies. The paper on electrothermal processes deals with the electric furnaces for melting and heat treatment, the production of ferro-alloys, pig-iron, steel, fixation of atmospheric nitrogen and the temperature control of furnaces. A few installations are described. 36 references. Ha (7b)

The Electrolytic Metallurgy of Zinc. (La Metallurgy du Zinc par Voie Electrolytique.) L. C. STURBELLE. *Revue Universelle des Mines,* Series 8, Vol. 7, Feb. 15, 1932, pages 224-232.

After a historical review of the electrolytic production of Zn the 3 main processes now in operation are described, that is the Anaconda or Standard process, with a weak acid solution, the Tainton process with high acidity, and the Sturbelle process, with a medium acidity, now in use in Belgium. The extraction amounts to 87-88%, 90-92% and 94-98% respectively for the 3 methods. The cost of installation per ton per day production are 2,000,000 frs., 1,400,000 frs. and 1,000,000 frs. respectively. It is very important that the cost for electric current is low; the author figures $20.00 per HP per year. In Belgium there are still many residues left from smelting processes which are now worked over with profit by the new process. Ha (7b)

Preparation of Metallic Lanthanum Free From Iron and Silicon (Préparation de lanthane métallique exemt de fer et de silicum). FELIX TROMBE. *Comptes Rendus,* Vol. 194, May 9, 1932, pages 1653-1655.

A description has already been given of the method employed by the author for the preparation of metallic Ce (*Comptes Rendus,* Vol. 193, 1931, page 421). By using a similar method he has been able to obtain metallic La free from Fe and Si. The composition of the electrolytic bath used in these tests was as follows: 60% anhydrous lanthanum chloride, 35% KCl and 5% precipitated CaF_2. A carbon crucible served as anode. This crucible contained a quartz or fluorite crucible which served to receive the metal deposited upon the cathode and to prevent its contact with the carbon tube. At the center of the quartz crucible a rotating Mo cathode was placed. The upper part of this cathode was protected by means of a quartz or fluorite tube. The cathode rotated at a speed of about 1 turn per second. Such rotation is absolutely essential if homogeneity of the bath is to be insured. A temperature of between 960° and 980° C. was employed, and a current of about 12 amp./25 g. of lanthanum chloride was used. The voltage of the cell was 7 and the cathode current density about 4 amp./cm.² The metal obtained represented 65% of that contained in the bath. Spectrographic examination insured the absence of Ca, Al and Si in the metal. Metal prepared in a quartz crucible, however, contained 0.3-0.9% Si. The purest samples showed the following properties: melting point, 885° ± 5° C.; Brinell hardness, 36; density, 6.139. OWE (7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Coating Industry Recognizes Prestige of Deep, Side-Heated Galvanizing Pots. *Steel,* Vol. 90, Jan. 4, 1932, page 169.

Improvements in the galvanizing industry during 1931 include the development of a new flux and of a new bright-dip cleaning method, a wider use of deep kettle installations and the application of diffusion flame burners, the development of alloy coatings to protect zinc surfaces, and the use of vulcanized rubber and acid-proof brick for lining pickling tanks. Other developments of interest are a new line of continuous cleaning, rinsing and drying machinery, continuous pickling equipment, new pickling machinery made of acid-resisting parts, and new galvanizing machinery. Improvements in the vitreous coating industry for 1931 include greater workability of acid-resisting enamels, the development of a new metal cleaner, the development of a new color chart, the completion of a large enameled metal tile manufacturing plant, and the proposal to build first exterior porcelain enameled metal house. JN (8)

Aluminum Coated Iron. (Aluminiertes Eisen). A. Karsten. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Mar. 20, 1932, page 121.

The Schoop metal spray method is described as utilized for Al coating. Schoop previously melted the metals with gas, melting in an electric arc is now used. GN (8)

The Electrolytic Coating of Metals with Lead Peroxide and its Anti-Corrosion Properties. (Die elektrolytische Ueberziehung der Metalle mit Bleisuperoxyd und ihre Anti-Korrosions-Eigenschaften.) N. Isgarischew & A. Kuznezova. *Zeitschrift für Elektrochemie,* Vol. 37, July 1931, pages 359-362; *Tzvetnuie Metallui,* No. 4, Sept. 1931, pages 449-453.

Optimum conditions were investigated for obtaining electrolytically a continuous coating of lead peroxide which would protect Cu or Fe against corrosion and at the same time give them a good appearance. Preliminary experiments showed that the best coatings on Cu and brass are obtained at the concentration of NaOH-1.0 N and Pb - 10.5 g. of $Pb(OH)_2$ per liter of H_2O, using current density of 0.3 to 0.4 amps./in.^{2} at 60° C. However the coatings were not very tenacious and did not fill pores and pits on the surface of the metal. Influence of various organic and inorganic substances was investigated, and it was found that the addition of small amounts of resorcin, tannin, glucose, glycerine, hypochlorite, ammonium persulphate with glucose, perborate with glucose, result in black, tenacious and elastic coatings on Cu or brass surface. Fe or steel may also be coated after preliminary plating with Cu; good coatings may be obtained directly on cast Fe by adding small amounts of glucose (0.1%) and perborate (0.25%), or glucose and ammonium persulphate (0.25%). The coatings on Cu plates stood an indefinite number of bends without breaking; Fe plates without preliminary Cu plating stood 2-3 bends. Tests also showed that the coatings resist well the atmospheric, tap water and salt water corrosion. 5.0% H_2SO_4 does not affect the coating, but strong sulphuric and nitric acids diffuse through the coating and dissolve metal; coatings do not protect against strong HCl. BND (8)

Metallic Cementation of Ferrous Alloys (La Cémentation Métallique des Alliages Ferreux). Joseph Laissus. *Aciers Spéciaux, Métaux et Alliages,* Vol. 7, Feb. 1932, pages 43-51.

The author applies the term cementation to any mutual action of 2 solid metals or metalloids in view of their penetration of one into the body of the other metal. In 1894, Spring showed that certain metals can penetrate one into another by heating them together above the melting point of one of the metals. Masing, in 1909, confirmed the experience of Spring by thermal analysis, microscopic examination and also using the effect of variation in electric conductivity corresponding to the progressive formation of solid solutions. H. Weiss, in his doctorate thesis, 1923, was the first one to make a systematic study of this important problem of metallic cementation (Thése de doctorat, Paris, *Ann.de Chim.Gén.* Serie T. Vol. XIX, June 1923; *Revue de Métallurgie,* Jan. 1924). He used couples made of Cu as one part and Zn, Sn, Al, Sb, Fe, Hg, Au, Ni and Ag as the other part. The work of other investigators on diffusion of metals in Fe is also discussed. Laissus made a complete study on metallic cementation especially on diffusion of Cr, W, Mo, Ta, V, Co, B, Ti, Zr and U in Fe and steel. His plan of study consisted in: (a) Preliminary study of the equilibrium diagram, (b) Experimental realization of cementation, (c) Study of different factors of cementation, (d) Study of principal properties of products obtained, (e) Interpretation of results and conclusions. Rustless-Steel-Lined Copper Utensils are finished with Arc-Welded Edge. *Iron Age,* Vol. 128, Dec. 17, 1931, page 1555.

Description of a method of combining the high Cr-Ni alloy and Cu employed by the Joseph Heinrichs Corp., Long Island City. A liquid-tight joint on the edge is made by arc-welding. Utensils are highly desirable for cooking in hotels and restaurants. VSP (8)

The Electric Oxidation of Aluminum. (Die elektrische Oxydation des Aluminiums.) *Aluminium,* Vol. 14, Mar. 31, 1932, pages 3-5.

A very resistant oxide coating on Al and its alloys is produced by the Eloxal bath which contains oxalic and chromic acid at a temperature of 15-30° C. The oxide film consists of γ-oxide very finely distributed. A thickness of 20-30 thousandth mm. has a breakdown strength of 300-400 volts. On flexible surfaces the hydroxide is used instead of the γ-oxide. The different applications of oxidation are discussed. Ha (8)

Tests on "Duralplat." (Untersuchung von Duralplatblechen.) K. Schraivogel & K. O. Schmidt. *Zeitschrift für Metallkunde,* Vol. 24, Mar. 1932, pages 57-62.

A detailed study of the properties of "Duralplat" (duralumin clad with a surface layer of a Cu-free, corrosion-resisting, hardenable and high-strength Al alloy), including tensile curves, bending test data, Erichsen ductility data, corrosion data with the effect of corrosion on strength properties. Like "Alclad," "Duralplat" corrodes only in the surface layer. After 30-day accelerated corrosion attack, 9½ months in salt spray, and 5½ months in the Baltic, the properties of the underlying duralumin were found unaffected, though uncoated duralumin under the same conditions was affected after a very short time. RFM (8)

Surface Problems of Materials. (Oberflächen-Probleme bei Werkstoffen.) *Oberflächentechnik,* Vol. 9, Apr. 19, 1932, pages 81-82.

The methods of treating metallic surfaces so that they fulfill certain requirements are discussed and reviewed. Rolls which must keep their grip in spite of wear on the material passing through them should be very hard which is best obtained by alloying with Si. A corrosion-proof surface can be produced, besides the natural protecting films which some metals develop, by coating with "tornesite" or "herolithe" which adhere extremely firmly to the metal surface and do not shrink, tear or spall; they do not soften by heat. Metallic coatings should be very thin as they adhere better and generally give better protection than thicker ones; metals which are electrochemically baser than the material on which they are deposited give better protection; Cr platings are now used up to 2 mm. thick. To produce heat-proof surfaces use is made of the fact that Al diffuses several mm. into the surfaces of cast Fe and steel; these methods are "alitizing" and "alumetizing." To make surfaces of non-conductors electrically conducting spraying of metals is used to good advantage. Ha (8)

New Swedish Method of Surface Enrichment with Aluminum according to Johannson. (Neues schwedisches Aluminisierungsverfahren Johannsen.) *Die Röhrenindustrie,* Vol. 24, Jan. 29, 1931, pages 30-31.

Note on scaling tests with aluminized tubes of 0.15% C carried out by the Sanvikens Jernverks Aktiebolag. The tubes perfectly withstood scaling tests at 800° and 920° C. for 24 hours. More severe conditions at 990° C. and 96 hours testing time also proved a marked protection of the aluminum-coated areas. Micro-investigations of samples held between 500° and 900° C. revealed that at 750° C. micro-structural changes begin. Corrosion tests in HNO_3 showed contradictory results. Atmospheric corrosion tests on samples with and without an Al-coating, showed appreciable rusting of the unprotected tubes and no effect on the aluminized samples. Similar results were obtained with tests in the pickling department, Duffek Corrosion Tester and other laboratory tests. No information on the coating method itself is given. EF (8)

Brittleness of Zinc Coated Steel. J. S. Adelson. *Heat Treating & Forging,* Vol. 18, Mar. 1932, pages 180-183; *Blast Furnace & Steel Plant,* Vol. 20, May 1932, pages 430-432, 435.

Method of Zn deposition is not the basic cause of the brittleness of Zn-coated steel. It can develop in steel coated by any method of Zn application. Results of investigation carried out with S.A.E. 1010 steel indicate that this brittleness is generally the result of a combination of factors. These factors are presence of a coating of Zn, which penetrates into the grain boundaries of the steel; amount of cold work in the steel; heating the steel to 750°-950° F. during or subsequent to the application of Zn; prolonged heating cycle; strain in the steel during the heating period; and heterogeneity of the steel. To prevent or minimize this embrittlement, such precautions as are commercially possible should be taken during manufacture and during the service life of the material to eliminate effects of these factors. Although hot-dip galvanizing must be done within the critical temperature range, sherardizing temperatures should be controlled to maintain them outside the range. If the use of these temperatures is unavoidable, the steel should be annealed before the Zn is applied. Care should be exercised in subjecting the material to fatigue. MS (8)

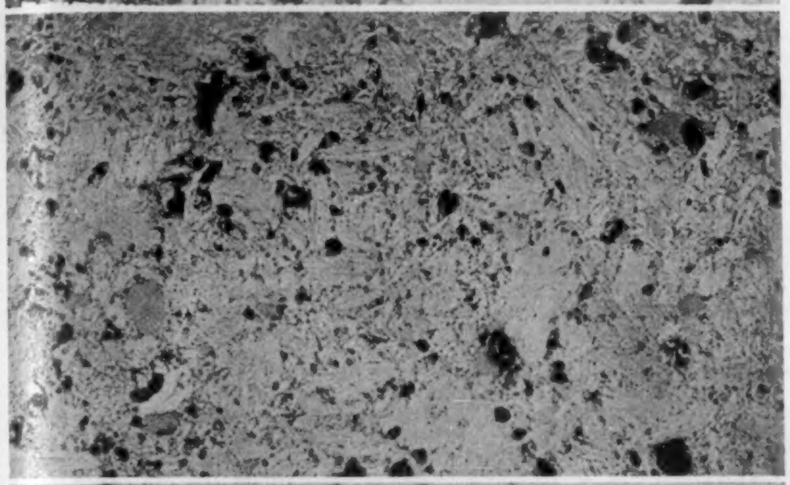
Corrosion-Resistant Material Made with Metallic Adhesive. A. W. Coffman (Mellon Institute of Industrial Research). *Chemical & Metallurgical Engineering,* Vol. 39, Mar. 1932, pages 144-145.

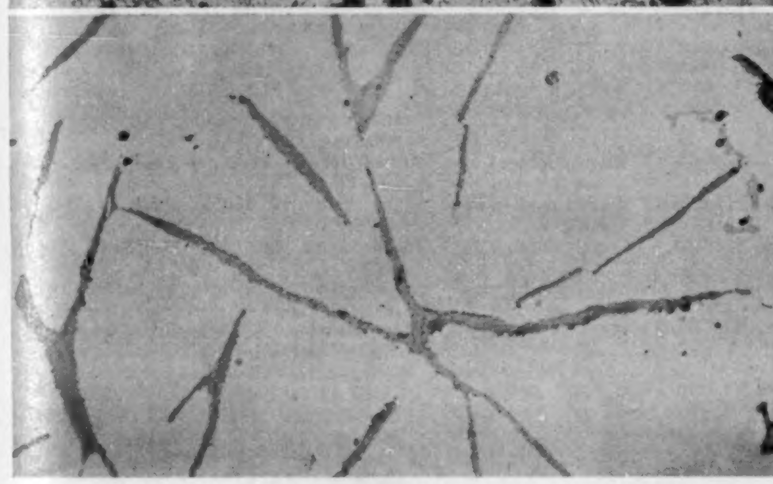
Descriptive of Robertson-Bonded-Metal, which in its finished form consists of 4 layers, any one of which may be changed to meet the corrosive conditions involved. They are (1) base metal, (2) metal adhesive of Zn, Pb, Sn or terne, etc., (3) felt or asbestos which may be saturated with a variety of materials to meet conditions of exposure, (4) waterproofing and decorative layer of paint, wood veneer, etc. PRK (8)

Cathode Sputtering, A Commercial Application. H. F. Furth. *Physics.* Vol. 2, Apr. 1932, pages 280-288.

Cathode sputtering cannot compete with the more common processes of metallic deposition, but in many special cases it can be employed where other methods are inapplicable. This is especially true (1) when metals are to be deposited upon non-conductors, (2) when the surfaces to be metallized would be injured by contact with chemical solutions or high temperature, (3) when either a very thin continuous metal coat or a very smooth, highly reflecting coat is desired, (4) when metals are to be deposited that are very difficult to deposit in any other manner, such as Si, Te, or Se, and (5) when a metal is to be deposited upon another metal far removed from it in the electrochemical series, such as Au or Pt upon Al or Mg. The theory of cathode sputtering with the advantages and limitations in the application is discussed, followed by a description of the commercial equipment and methods for applying Au electrode surfaces to diaphragms of certain types of microphones. By proper design of the vacuum chamber and the inside parts, a fairly uniform discharge current density and a uniform deposit is obtained. A constant sputtering rate is produced by the use of a bleeder valve which maintains a proper residual pressure. Adherence and continuity are obtained by the use of a special cleaning process. An extensive bibliography on cathode sputtering is included. WAT (8)

Readers' Comments—Continued





metallographic microscope or in the Leitz ore microscope, using polarized light. If cast iron is polished by the usual method it becomes difficult to observe the extinctions in polarized light.

I am further submitting a photomicrograph of a cast iron and a sample of Acheson graphite polished by the new method. This shows that graphite has a structure and is not black as had been supposed. The third photomicrograph is given merely as a matter of interest; it shows a particle of graphite surrounded by pearlite, the background being the carbide eutectic.

The above is not intended to detract from Mr. Vilella's worthy contribution but rather to strengthen his point of view.

University of Michigan, STEPHEN F. URBAN
Sept. 20, 1932.

To the Editor:—

I wish to extend my thanks to Mr. Urban and his associate Mr. Schneidewind for their pertinent and constructive comments on my article. It is indeed gratifying to know that my effort has received the approval of men who are themselves authors of a notable contribution on the same subject.

J. R. VILELLA

Sept. 25, 1932

Applications of Copper and Its Alloys in Buildings. (Les Applications du Cuivre et des ses Alliages dans le Batiment.) *Cuivre et Laiton,* Vol. 5, Feb. 29, 1932, pages 77-82; Mar. 15, 1932, pages 103-112.

The many applications of Cu for roofing, window sills, gutters and plumbing, apparatus and particularly for ornamental purposes are reviewed and economical advantages over other materials pointed out; a greater use in France is advocated. Ha (9)

Aluminum in Architecture and Structural Building. (Das Aluminium in der Architektur und im Bauwesen.) *Aluminium,* Vol. 14, Apr. 15, 1932, pages 5-6.

The advantages of Al against the usual metallic building material are pointed out among which are foremost the resistance to atmospheric influences, lightness, cheapness of machining due to high cutting velocities and long life. In addition, Al scrap has a much greater value than Fe scrap. Ha (9)

Results of the International Contest 1931 for the Development of the Consumption of Aluminum and Its Alloys (Ergebnisse des Internationalen Wettbewerbs 1931 für die Entwicklung des Verbrauches von Aluminium und seinen Legierungen). *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 4, Mar. 1932, pages 43-71.

The results of the first international competition for suggestions and methods to develop the use of Al are fully reported; the propositions comprise 28 different fields. The prizes were given to the authors of the use in tanning of leather and in the construction of radiators for central heating systems. The proposed applications in all 28 fields are described in detail and sketches illustrate the methods of use. The rules for the second competition in 1932 are reprinted. Ha (9)

Graphophone Records of Aluminum. (Grammophonplatten aus Aluminium.) *Aluminum,* Vol. 14, Mar. 31, 1932, pages 5-6.

Al discs are coated with a special lacquer into which the acoustic record is pressed. These records are said to be absolutely equal to the present shellac records. By heating to 80° C. the acoustic grooves disappear and a new record can be pressed on. The weight is about 50 g. against 200 g. of the usual record and the thickness 0.5 against 2 mm. Ha (9)

Copper Tubes in Domestic Plumbing. (Le Tube en Cuivre dans les canalisations d'eau domestiques.) *Cuivre et Laiton,* Vol. 5, Jan. 15, 1932, pages 7-12.

Commercial dimensions in France, Germany and Belgium are tabulated, tools and methods for cutting, threading, bending are illustrated, the different joints are explained and the economies possible by the use of Cu over other materials discussed. A list of 23 bibliographical references on this matter is added. Ha (9)

Pulp and Paper Engineers Discuss Materials of Construction. *Chemical & Metallurgical Engineering,* Vol. 39, Mar. 1932, pages 153-154.

Report of Meeting of Technical Association of Pulp & Paper Industry, Feb. 15, 1932. The following tabulates the results of the meeting:

Metal	Use	Service
18 Cr–8 Ni	Blowpit bottom	Satistactory after 3 years
	Relief strainer	Failed: using 85 Cu, 10 Sn, 5 Zn
	Fabricated Strainers	1 failure in 3 years
	Cast "	3 years
	Side relief valves	In use 2½ years: bronze fails in 3 months
	Digestor Castings	Better the higher the Cr for machining resists bisulphite liquor, hot SO_2 gas and waste liquor
	Digestor relief lines	4 years; occasional failure after installation
Copper	Top relief lines	Better than brass
Monel Metal	Stem of Blow valves	Better than acid resisting bronze
Iron pipe	Bleach lines	Suitable if filled
Wrought iron	" "	Good for 1 year
Cast Ni iron	" "	In service 3 years
Cast iron valves	" "	20 years
14 Ni, 6 Cu, 2 Cr, rest iron	Valves and pumps in digestors	Better than cast iron
Carbon	Sulphite and kraft digestors	Satisfactory
Lumber treated with zinc chloride	Roofs	Increases service life of untreated lumber 3-5 times

Copper-Steel in the Manufacture of Hardware. (L'acier au cuivre dans la confection des serrures charmiéres et matériel simlaire). *Cuivre et Laiton,* Vol. 4, Aug. 30, 1931, page 387.

The advantages of non-rusting Cu steel in the manufacture of locks, hinges, chains and similar hardware is pointed out and its wider use is recommended. Ha (9)

Geared Motors. *Electrical Review,* Vol. 109, Dec. 11, 1931, pages 879-880.

Improvements in alloy steels have aided developments in modern reduction gearing. In one type of British geared motor, pinions aré made of nitralloy steel. In single-reduction units, final shaft is made from 3½% Ni steel having a tensile strength of 65 tons/in.[2] Units with double or treble reduction have compound shafts made from Ni-Cr-Mo steel having a tensile strength of 65 tons/in.[2] MS (9)

Wearing Parts of Crushing and Grinding Machinery. *Edgar Allen News,* Vol. 10, May 1932, pages 80-83.

A special Cr alloy steel is used for the wearing parts of ball mills, tube mills, rod mills, etc. They have the advantage of being more easily machined than Mn steel, have a high elastic ratio and a Brinell hardness of 255. Several parts and their details are illustrated. Ha (9)

Paper Milk Bottles (Bottighe du latte in cartone). *Alluminio,* Vol. 1, Jan.-Feb. 1932, pages 42-43.

Paraffined card board, Al foil lined milk bottles, used in Paris and Egypt, are illustrated. They are sterilized by ultra-violet rays. HWG (9)

HEAT TREATMENT (10)

Heat Treating Rivet Sets. Recommended Practices Committee A. S. S. T. *Metal Progress,* Vol. 21, Apr. 1932, page 67.

Tentative recommendations for forging, normalizing, tempering and annealing temperatures are made. Hardening temperature and medium are recommended with the hardnesses to be expected for plain carbon and alloy steels commonly used for rivet sets. WLC (10)

Deformation of Steel in Heat Treatment. PORTEVIN & SOURDILLON. *Iron Age,* Vol. 129, Feb. 25, 1932, page 492.

Abstract translation of article in *Revue de Metallurgie,* June and July 1931. Gives data from experiments conducted on exact measurement of changes as in the diameter, length and hardness produced in cylindrical specimens of various types of steel by different heat treatments. See "Deformations Accompanying Thermal Treatment of Steel," *Metals & Alloys,* Vol. 2, Nov. 1931, page 263. VSP (10)

Heat Treatment and Carburizing of Steel. (Tempera e cementazione dell' acciaio.) MARIO LEVI-MALVANO. Ulrico Hoepli, Milan, 1929. 2nd edition. Board covers, 4¼ x 6¼ inches, 306 pages. Price 20 lire.

The book starts with a discussion of equilibrium diagrams in general, then discusses the Fe-C diagram, and so leads up to the theory and practice of heat-treating and carburizing. Furnaces and pyrometry are dealt with, there is a chapter on macro-etching, and the volume ends with a description of the metallurgical laboratory at the Instituto Scientifico Breda at Milan.

A good deal of recent work is included, and credited to various workers, but there are no literature references and no alphabetical index.

The keynote of the little volume is the application of theory to practice. The fundamentals are quite well brought out. H. W. Gillett (10)-B-

Hardening (10a)

Treating Parts for Non-Uniform Hardness. *Metal Progress,* Vol. 21, Mar. 1932, pages 47-52.

A description of differential hardening practice and equipment at the River Rouge plant of Ford Motor Co. Selective heating by means of low voltage currents of high amperage is being used successfully. Differential quenching by means of jets of coolant (principally caustic solution 10° Beaumé at 85° F.) is also employed. WLC (10a)

Difficult Hardening. (Schwierige Härtungen.) A. NAUCK. *Das Werkzeug,* Supplement to *Maschinenbaukonstrukteur-Betriebstechnik,* Vol. 8, Feb. 10, 1932, pages 26-27.

Considers the continuous hardening of wires; the hardness of bearings, of low-C steel, of small steel rolls, of complex tools, and of oscillating steel strips; partial hardening; the hardness of rapidly revolving pistons; cooling of hollow shapes; hardening in the lead bath; heating for hardness. MAB (10a)

Investigation of Steel Hardening. (Untersuchungen über die Stahlhärtung.) NIELS ENGEL. Ingeniroidenskabelige Skifter A No. 31, Danmarks Naturvidenskabelige Samfund, Kbenhavn, 1931. Paper, 6½ x 9¾ inches, 190 pages. Price 10 Kroners.

It is by reading monographs as this that it is realized how much even of very familiar phenomena still remains to be explained although practice may already have arrived at a fairly high grade of perfection. The present work treats the hardening process of steel of which so much has been written and yet it seems that all prescriptions and recipes to obtain an excellent product, rest more or less on an empirical basis. This was the reason for the author starting a thorough investigation to find what really constitutes the hardening of steel. We know that the steel must be converted into an austenitic structure for a successful hardening process, and how this can be done is the principal question bound up with the thermal phenomena of cooling and quenching. Quenching is defined as a cooling of a metal in such manner that those physical phenomena which would take place at slow cooling are suppressed either entirely or partially because they do not have time to develop fully. For this reason the cooling process is of prime importance. The author treats, consequently, first the process of quenching, second the importance of the cooling velocity in the hardening of steel. From these 2 studies he then tries to develop a theory of hardening which would put the practical steel man in a position to understand his problems so clearly that for each individual case he can find the proper solution. A diagram is developed showing the 4 possible conversions of austenite of which only 3 are of importance to hardening and indicating the formation velocity of the conversion as a function of temperature. The hardness is bound up with a certain arrangement of the carbon atoms in the lattice in such form that the sliding planes are blocked and prevent a deformation of the lattice structure formed in the hardening process. Based on these results the changes of physical properties due to hardening are explained in the last chapter. A number of diagrams illustrating these results are reproduced in 8 plates. The book is written in simple, clear language, and should be on the desk of every practical steel man. M. Hartenheim (10a)-B-

Electric Hardening of High Speed Steel. A Consideration of the Factors Influencing the Heat-Treatment of High Speed Steel in relation to the Type of Plant Used. A. G. ROBIETTE. *Iron & Steel Industry & British Foundryman,* Vol. 5, Jan. 1932, pages 171-177.

A discussion of the theoretical considerations present in the hardening of high speed steel. The use of salt baths is given preference over box-type electric furnaces. A new design in salt baths is described in which the passage of current through the pieces being hardened is eliminated by placing the electrodes close together on one side of the bath so that the working portion of the bath is kept distinct from the heating zone. CHL (10a)

CASE HARDENING & NITROGEN HARDENING (10c)

Contribution to the Knowledge of Metal Nitrides. (Beiträge zur Kenntnis der Metallnitride.) JEAN RIEBER. Doctor's thesis, Technische Hochschule Hannover, 1930. Paper, 45 pages.

The chief purpose of this study was the preparation of pure nitrides of the following metals: Mg, Ca, Sr, Ba, Be, Al, B, Ti, Fe, Zr and Cu.

A general review of the previous work done by other investigators on preparation of nitrides, introduces this study.

Experimental work is then discussed in detail. The author used purified nitrogen gas and ammonia as sources of nitrogen. Pure nitrogen was prepared by passing the nitrogen from the tank through a purifying train consisting of (a) heated copper chips, (b) alkaline solution of hydrosulphite, (c) H_2SO_4, (d) P_2O_5.

Ammonia gas was purified by passing over soda lime, Na metal and then condensed at -78° C.

The method of preparation of each nitride varies with the metal; from the detailed description of preparation and of the results obtained the following table would illustrate the main points of this work.

TABLE I. PREPARATION OF METAL NITRIDES

Metal Nitrides and % of Nitrogen	Source of Metal and of Nitrogen	Treatment	Product Obtained and % of Nitrogen
Mg_3N_2 (27.72)	Mg, Metal (99.7%); N_2, gas	4-5 hours at 800-850°C.	Mg_3N_2 (27.67; 27.84; 27.69% N)
Mg_3N_2	Mg, Metal; NH_3, gas	2 hours at 800-850°C., then cooled in stream of ammonia	$Mg_3N_2.xNH_3$ (29.84 to 38% N)
Ca_3N_2 (18.89)	Ca, metal; N_2, gas	16 hours at 800°C. then 4 hours at 1000°C.	Ca_3N_2 (18.31-18.69% N)
Ca_3N_2	Ca, metal; NH_3, gas	16 hours at 850-900°C. and then for 1 hour at 1150° C. with a slow cooling in stream of ammonia	$Ca_3N_2.xNH_3$ (20.86-22.82% N)
Sr_3N_2 (9.63)	Sr, metal; N_2, gas	5 hours at 850-900°C.	Sr_3N_2 (9.34% N)
Sr_3N_2	Sr, metal; NH_3, gas	3 hours at 850-900°C. and then cooled during 2½ hours in stream of ammonia	$Sr_3N_2.xNH_3$ (11.7% N)
Ba_3N_2 (6.36)	Ba, metal; N_2, gas	5-6 hours at 500-550°C.	Ba_3N_2 (7.27% N)
Ba_3N_2	Ba, metal; NH_3, gas	5-6 hours at 700°C.	$Ba_3N_2.xNH_3$ (13.8% N)
Be_3N_2 (50.66)	Be, metal; N_2, gas	Long Heating at 1000° to 1100°C.	Be_3N_2 (45% N)
Be_3N_2	Be, metal; NH_3, gas	12 hours at 950°C. and then 2½ hours at 1050°C.	Be_3N_2 (49% N)
AlN (34.08)	Al, metal; N_2, gas or NH_3, gas	At 800-860°C. for few hours	AlN (33.36% N)
BN (56.4)	Borax, NH_4Cl	Heat borax for 6 hours at 800-850°C. then pure NH_4Cl is added and heated for 10 minutes	BN (56.08% N)
Fe_yN_x	Freshly reduced Iron and N_2	Heated for 20 hours at 700°C.	Fe_yN_x (0.2-0.3% N)
Fe_2N (11.15)	Freshly reduced Fe; NH_3	15-20 hours at 450°C.	Fe_2N (10.6% N)
Fe_5N_2 (9.73)	Freshly reduced Fe; NH_3	15-20 hours at 475-500°C.	Fe_5N_2 (9.21% N)
Fe_yN_x	$FeCl_2$-$2H_2O$; NH_3	4 hours at 630-650°C.	Fe_yN_x (6.35% N)
	$FeCl_2$ subl.; NH_3	3 hours at 700° C.	Fe_yN_x (4.7% N)
	$FeBr_2$-H_2O; NH_3	2½ hours at 680°C., this product was magnetic. After 20 more hours at 450-475°C. This product took up more nitrogen	Fe_yN_x (8.1% N) Fe_yN_x (10.0% N)
	$FeCl_2$-$2H_2O$; NH_3	2 hours at 700°C.; magnetic	Fe_yN_x (6.0% N)
	$FeCl_2$-subl.	2 hours at 700°C.; magnetic	Fe_yN_x (3.6% N)
	$FeCl_2$-subl.	3½ hours at 630-650° C.; magnetic	Fe_yN_x (6.94% N)
Fe_2N (11.15)		After 48 more hours at 450°C.; non-magnetic	Fe_2N (10.6% N)
Fe_4N (5.90)	Fe_2N	Heating Fe_2N at 550°C.	Fe_4N (5.9% N)
TiN (22.56)	$TiCl_4$; NH_3	10 hours at 1200°-1300°C.	TiN (22.21% N)
ZrN (13.39)	Zr, metal; NH_3	5 hours at 1100-1200°C.	ZrN (12.42% N)

Copper nitride cannot be obtained in pure form, it usually contains two other elements such as hydrogen and oxygen.

Temperature of decomposition of some of these nitrides has been determined. Be_3N_2, BN, TiN, ZrN decompose above 1100° C., Mg_3N_2 at 1150° C.; Cr_3N_2, Br_3N_2, and Sr_3N_2 above 1100° C.; AlN above 1400° C.; Fe_4N at 650° C.; Fe_2 N at 550° C., and Fe_5N_2 at 750° C. G.T.Motok (10c) -B-

Quenching (10d)

New Results of the Influence of Quenching in Water on Mild Steels. (Nouveaux Résultats sur la Trempe à l'Eau des Aciers Doux.) J. SEIGLE. *Génie Civil,* Vol. 99, Oct. 17, 1931, pages 395-398.

The author summarizes the results of a thesis by Allan Bates on the effect of quenching on the strength of mild steels as a function of the quenching temperature and of the time elapsed after quenching. The hardening effect of quenching increases considerably during the first 3 or 4 weeks after quenching; equilibrium diagrams and microphotographs are discussed and it is stated that the aging can be explained by a precipitation of cementite particles which are very fine and invisible with our present appliances; this precipitation goes on during the whole time of aging. Ha (10d)

Drawing (10e)

Drawing of High Speed Steels. (Etude sur la revenue des aciers à coupe rapide.) André Michel & Pierre Benazet. *Revue de Métallurgie*, Vol. 29, May 1932, pages 259-275.

Conclusions of Sagasawa (*Revue de Métallurgie*, Vol. 20, Jan. 1925, page 92) regarding the decomposition of austenite in quenched high speed steel into austenite and martensite on drawing from moderately high temperatures were confirmed. It was found that for these steels containing large amounts of Co and quenched into austenitic state the first drawing does not destroy all austenite. The transformation and increase of hardness continue on the subsequent draws, provided that the soaking time is normal. This investigation was conducted on steels containing approximately 0.72-0.80 C, 5.0-5.6 Cr, 18-19 W, 1.0-1.5 V to which different amounts of Co were added. More than 5% Co facilitates the austenitic structure on quenching. On cooling from not too high temperatures and normal soaking time the γ-α transformation occurs under about 250° C. but with greater than 10% Co content the decomposition becomes more sluggish and for proper hardening several draws are required. This was checked with a dilatometer and by cutting tests. Longer soaking results in some decomposition of austenite. 4 hours at 600° C. slightly increase the transformation on cooling. For complete hardening on drawing a steel with not more than 11% Co 24 hours at this temperature are sufficient with a single draw. At 660° C. 2 hours soaking will lead to complete hardening on cooling of steels containing not more than 17% Co while longer soaking at the same temperature permitted all steels which have been investigated to harden fully on a single draw. Isothermal heating at 600° C. for 24 hours did not show any appreciable effect on steels having up to 11% Co, though it appears that with 20% Co the transformation is somewhat easier. Soaking at 650° C. for 2 hours caused some decomposition in all steels investigated, but the resultant hardness is lower than with the usual draw. Some evidence is presented to support Tammann and Erich Scheil conclusions that these irregularities in drawing phenomena are connected with the pressure exerted by the formation of martensite. See also *Metals & Alloys*, Vol. 2, July 1931, page 132. JDG (10e)

Time Factor in Tempering Dies. Bernard Thomas. *Heat Treating & Forging*, Vol. 18, Jan. 1932, pages 35-38.

2 objectives aimed at in tempering are removal of stresses and production of particular physical structures. In general, the first objective occupies a minor part in the function of tempering, and it is the second which needs time to be achieved successfully. This factor of time is of great importance because of the necessity of formation of the physical structures and properties for best results and because of the size of the article being treated. To obtain the best results from a tempering operation, it is necessary to determine the most suitable physical structure or combination of structures. Having decided this point either by experience or investigation, the necessary approximate temperature may be determined. Using too high a temperature even for a short time will produce inferior results. MS (10e)

Aging (10f)

The Aging of Hardened Carbon Steel. *Metallurgist*, Sept. 1931, pages 131-132.

An extended abstract of a paper by Steinberg & Subow appearing in *Stahl und Eisen*, Vol. 51, July 16, 1931. See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 42. VVK (10f)

Age Hardening Phenomena in Typical-Fusion-Weld Metal. F. R. Hensel & E. I. Larsen. *Transactions, American Society for Steel Treating*, Vol. 19, May 1932, pages 639-672.

Includes 16 references and discussion. The authors report study of the age hardening phenomena in weld metal due to presence of precipitating nitrides of Fe. Arc and gas welds of low C steel and ingot iron are compared. A maximum of 0.05% N_2 must be held if satisfactory ductility is to be maintained. Arc welds contain 0.10 to 0.15% N_2 and show pronounced age hardening; after quenching at 1110° F. aging proceeds at room temperature. Gas and atomic hydrogen welds produce superior welds with bare wire showing only negligible embrittlement due to aging. All types of weld metal showed extreme "abnormality" according to the McQuaid-Ehn test. Data on the effect of the age hardening properties of such weld metal on its magnetic properties and electrical resistance are presented. Micrographs show the structures observed in the welds studied. WLC (10f)

The Age-Hardening of Alloys. C. H. Desch. *Sibley Journal of Engineering*, Vol. 46, Mar. 1932, pages 65, 66, 83.

The general principles of precipitation hardening are discussed, with the Al-$CuAl_2$ and Fe-Fe_4N diagrams as examples. The development of Lüders' lines revealed in a mild steel tensile specimen slightly stretched, heated to 200° C. by etching in an acid Cu solution is said to be entirely due to the presence of N and steels too low in N to show age-hardening do not show the effect. Precipitation of nitride in and resultant brittleness of boiler steel during operation are stated to account for certain instances of boiler failures. HWG (10f)

Aging in Low-Carbon Steels. A. Allen Bates. *Transactions American Society for Steel Treating*, Vol. 19, Mar. 1932, pages 449-480.

Includes discussion. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 15. WLC (10f)

Precipitation Hardening with Special Reference to Experiences Gained on Light Metals and Alloys of Beryllium. (Ausscheidungshärtung-Vergütung insbesonders auf Grund der Erfahrungen an Leichtmetallen und an Legierungen des Berylliums.) G. Masing. *Die Metallbörse*, Vol. 21, June 13, 1931, page 1110.

Summarizes a lecture at the 36th General Meeting of the Deutsche Bunsengesellschaft für angewandte physikalische Chemie, Vienna, 1931. See *Metals & Alloys*, Vol. 3, June 1932, page MA 174. EF (10f)

Improvement of High-Alloy Austenitic Nickel-Chrome Steel by Carbide Precipitation Hardening. E. Greulich. *Foundry Trade Journal*, Vol. 46, Mar. 31, 1932, page 208.

Abstract of a paper which appeared in *Archiv für Eisenhüttenwesen*. See *Metals & Alloys*, Vol. 3, June 1932, page MA 174. OWE (10f)

The Age-Hardening of Some Aluminum Alloys of High Purity. Marie L. V. Gayler & G. D. Preston (National Physical Laboratory). *Institute of Metals, Advance Copy* No. 591, Mar. 1932, 12 pages.

The effects of several elements on the age-hardening properties of Al alloys containing 4% Cu were investigated. Highly pure Al (99.96%) was used in preparing the alloys. It was found that 0.35% Fe inhibited age hardening at room temperature. This effect is partly counteracted by 0.25% Si, and is entirely eliminated by 0.5% Mg. X-ray and microscopic examination failed to indicate the mechanism of hardening at room temperature. It is suggested that age hardening of Duralumin at room temperature and at 200° C. is due to the same process, and that this hardening occurs prior to the actual precipitation of $CuAl_2$ or Mg_2Si. It is also suggested that both $CuAl_2$ and Mg_2Si are effective in hardening Duralumin. 11 references. JLG (10f)

The Course of Aging of Mild Steel and the Aging of Steels of Different Origin. (Ueber den zeitlichen Verlauf der Alterung weichen Stahls und über die alterung von Stählen verschiedener Herkunft.) V. v. Koeckritz. *Mitteilungen aus dem Forschungsinstitut der Vereinigte Stahlwerke Akt.-ges. Dortmund*, Vol. 2, No. 9, 1932, pages 193-222.

That phenomenon which causes an increase in the resistance of steels to deformation and a decrease in their capacity for deformation is generally called aging. For practical purposes the increased brittleness manifested in the notch-impact test is of special importance. A great number of tests were made to find the changes in aging for different manners of treatment of the steel, for instance, by interrupted tests where freshly made steels were subjected to loads up to a certain stress, then relieved and aged and again subjected to the same stress to final fracture and this at different temperatures. The fact that the course of tensile properties is parallel with certain hardening phenomena was demonstrated. Because of this fact the cause of aging is ascribed to the segregation or precipitation of a certain material or matter, the nature of which is as yet unknown. The similarity of changes due to aging and to hardening makes this assumption very probable. A magnetic analysis did not supply an explanation for the aging phenomenon although this fact does not contradict the previously described theory of aging as the segregations strongly influence the magnetic quantities by cold deformation. The tests made on a very great number of steels indicate the probability that 0 in the form of soluble oxide might be the originator of aging as of all steels tested Armco iron and Thomas steel show the strongest aging phenomena and these 2 steels contain the greatest amount of 0 due to their method of manufacture. For further details the paper with its tables and curves must be referred to. 35 references. Ha (10f)

Experiments on the Aging and Tempering of Duralumin. R. Hay. *Journal Royal Technical College* (Glasgow), Vol. 2, Jan. 1932, pages 601-608.

The view is expressed that the aging of duralumin alloys is due to the concentration of the solute at the grain boundaries and that tempering is brought about by precipitation resulting from supersaturation. The tempering curves obtained for duralumin are similar to those found for steels and can be expressed by the same general equation. In the phenomenon of age-hardening at least 2 independent factors occur. At low temperatures a gradual but uniform change in the properties occurs, and this change can be accounted for by the deposition of the particles of the separating phase in a highly disperse state. As the separating phase consists of aggregates of several molecules, diffusion must have occurred. Whether it is necessary for actual precipitation to occur is a debatable point as the observed phenomena can be accounted for by the concentration of the separating phase at the grain boundaries without actual precipitation occurring. The change at the higher temperatures involves, on the first assumption, the gradual coalescence of the disperse particles and, on the second assumption, the gradual precipitation of the concentrated phase at the grain boundaries. The experiments on tempering show that this second factor takes place in a series of steps, rapidly reaching a stable state for each temperature of tempering. This stepped equilibrium is more difficult to explain by the coalescence theory than by the precipitation at the grain boundary theory. By the latter the increased temperature will cause more rapid diffusion of the solute phase to the grain boundary so causing excessive concentration and precipitation of the excess material until a state of equilibrium is once again attained. A further increase of temperature will again upset the balance causing more solute to go to the boundaries and resulting in further deposition. WAT (10f)

Precipitation Hardening and Its Possibilities of Application. (Die Ausscheidungshärtung und ihre Anwendungsmöglichkeiten.) E. Dorgerloh. *Maschinenbau*, Vol. 11, Jan. 7, 1932, pages 5-7.

Rather complete descriptive account of the development in precipitation hardening theory and practice. Refers both to non-ferrous metals and to iron and its alloys. The article is particularly valuable on account of its giving extensive data of quenching and drawing temperatures and of the resulting hardness characteristic of the various metals. The designer's attention is called to the peculiar advantages of this type of hardening in comparison to quenching and other kinds of hardening. In this regard, the still maintained easy workability, the lack of internal stresses and prevention of hair cracks and within certain limits—the ease in obtaining special properties desired are mentioned. It is made possible to fully obtain a required hardness even in dealing with larger forgings or castings of complicated shape. A great number of references is cited. RFV (10f)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

Training Gas Welders for the Job. T. M. JONES. *Paper presented to the 32nd Annual Convention of the International Acetylene Association*, Chicago, Nov. 1931, 5 pages.
Outlines a plan of training consisting in selection of suitable material for training, development of the individual, and thorough practical instruction. Ha (11c)

The Welding of Electron Metal. (Die Schweissung von Elektronmetall.) H. A. HORN & K. TEWES. *Technisches Zentralblatt*, Vol. 41, Mar. 1931, pages 249-253; April 1931, pages 318-320.
Cast electron metal and the rolled material AM503 can be welded very satisfactorily. The welding rod must be of the same material, and the oxy-acetylene flame is the best suited. A Mg flux should be used which can easily be washed off later to avoid corrosion. Cast pieces of electron must be preheated. Microphotographs show the structure of electron welds. Ha (11c)

Methods in Fusion Welding. (Arbeitsverfahren in der Autogentechnik.) H. HOLLER. *Technisches Zentralblatt*, Vol. 41, Feb. 1931, pages 123-126.
The methods of left- and right-hand welding (Progressing and retrogressing) are explained and the advantages of both compared. The distance between 2 sheets depends on the length of the seam and the thickness of the sheets. General instructions are given. Ha (11c)

Electro-Welding in Reinforced Concrete Construction. (Die Elektroschweissung im Eisenbetonbau.) R. HOFFMANN. *Zement*, Vol. 20, Nov. 26, 1931, pages 1024-1026; Dec. 3, 1931, pages 1041-1042.
Data on amperage, voltage, power consumption, efficiency, electrode dimensions of electro welding. Then the particular welding performances are discussed which are required on the skeleton of reinforced concrete work with reference to (1) the proposal of Bondy, i.e., a casing with welded rims and welded slits, (2) the writer's suggestion, i.e., the use of a split casing with welded edges and longitudinal seam, (3) lap welded joint, and (4) stitched welded joint as a substitute for interwoven joints. Among the utilization of electro welding in reinforced concrete structural work, the application to the patents of Bauer is emphasized. Results from tests on welded rods are presented. EF (11c)

The Oxy-Acetylene-Welding of High-Grade Materials. (Die Azetylen-Sauerstoff-Schweissung hochwertiger Werkstoffe.) W. HOFFMAN. *Autogene Metallbearbeitung*. Vol. 25, Feb. 15, 1932, pages 49-52.
As a first requirement for a satisfactory weld of high-grade materials, especially structural steels St 34, St 37, St 52 (German standards) it is necessary that the added material have 100% of the static tensile properties of the piece itself. Several plain and alloyed welding wires are investigated in this respect. By proper selection of the welding wire, all high-grade steels for building can nowadays be welded by the gas-fusion welding method. Diagrams of endurance tests of welded and not welded materials are shown. Ha (11c)

Fusion Welding of Bodies of Vessels. (Autogen-Schweissung von Schiffskörpern.) HOELZERMANN. *Schmelzschweissung*, Vol. 11, Feb. 1932, pages 27-29.
Experience has shown that fusion welding can very well take the place of riveting for large parts without fear of warping deformation if the proper welding methods are applied. The costs for welding are lower than for riveting. Ha (11c)

Recent Development in Piping and Pipe Fittings for Welded Construction. S. HIRSCHBERG. *Paper read before the 32nd Annual Convention, International Acetylene Association, Chicago,* Nov. 1931, 9 pages.
The advantages of welded fittings which now are admitted by the A. S. M. E. Boiler Code, are pointed out and the design of pipe joints, elbows and tees, expansion bends, valves and headers and their manufacture briefly described. Ha (11c)

Adoption of Welding in Superstructure and Bridge Constructions made of Reinforced Concrete. (Anwendung der Schweissmethoden bei Hoch- und Brüchenbauten in Eisenbeton.) O. BONDY. *Zement*, Vol. 20, Aug. 20, 1931, pages 781-784.
The recent injection of welding into reinforced concrete structural work is demonstrated. Furthermore the writer touches upon the utilization of welding for iron skeletons of columns, the application to the patents of Bauer and the adoption of welding in making flexible steel fabric. Mentions in conclusion the different welding methods. EF (11c)

Are Welding in American and German Ship Yards. (Lichtbogenschweissung auf Werften in Amerika und in Deutschland.) LOTTMANN. *Werft, Reederei und Hafen*, Vol. 11, Sept. 7, 1930, pages 368-372.
The rapid progress of arc welding in ship building in both countries is reviewed. The information on the status of welding in the U. S. A. mainly refers to statements of J. W. Owens, Newport News. EF (11c)

What an Engineering Graduate Should Know about Welding. E. LUNN. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 5 pages.
General remarks on a curriculum recommended. Ha (11c)

Application of Gas Welding on Nickel Plate Road. J. C. MILLER. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 6 pages; *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 32-34.
The author describes repair of locomotive frames, cylinders, guides, stoker screws, certain parts of cars, battered rail ends and worn frogs by means of the oxy-acetylene welding process. Use of the oxy-acetylene cutting torch in the railway shop is also discussed. Detailed procedures and estimated savings are given. Ha+TEJ (11c)

Discussion of paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in Journal of the American Welding Society, Vol. 10, Oct. 1931, pages 43-44. See *Metals & Alloys*, Vol. 3, Apr. 1932, page MA 98. TEJ (11c)

Code for the Welded Construction of Low Pressure Tankage. *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 35-38.
Outline of proposed code covering the manufacture of stationary low pressure welded tanks for installation in buildings, prepared by the American Welding Society Committee on Building Codes. Excerpts of the Minneapolis Building Code pertaining to storage tanks, are also included. TEJ (11c)

Welding Applied to Aircraft Construction. P. F. TAYLOR. *Welding Journal*, Vol. 29, Jan. 1932, pages 18-20; Feb. 1932, pages 38-40.
Paper read before the North-Western Branch of the Institution of Welding Engineers, Jan. 1932. Welding has been successfully applied to aircraft since 1913. The author cites the advantages of welded construction. The most suitable composition of straight C steel for welded aircraft construction is: C 0.15-0.18%, Mn 0.30-0.50%, Si 0.30 max., S 0.04 max., P 0.04 max. A high Mn steel, containing 0.25-0.35% C and 1.5% Mn is used in some cases. Cr-Mo steel is the most suitable because of its high strength and toughness. This steel contains: C 0.25-0.35%, Mn 0.50%, Cr 0.80-1.00%, Mo 0.18-0.25%. A suitable welding rod contains: C 0.07%, Mn 0.28%, Si 0.015%, S 0.02%, P 0.02%. Procedure for welding Al is given as well as the composition of a suitable flux. Stainless steels for welding purposes should be of the austenitic type which contain 7 to 12% Ni and 14 to 20% Cr. A filling wire having a slightly higher Cr content is desirable. The author describes the proper welding procedure for this type of steel. Part II. The author discusses various oxy-acetylene welding defects, their causes and prevention. Unavoidable volume changes during welding are explained. The physical condition of a weld is improved by subsequent heat treatment. After describing the different types of joints used in aircraft welding, the author gives general rules for making repairs in welded structures. Precautions must be taken in order to minimize distortion. Procedure is outlined for the building of a typical welded steel fuselage. TEJ (11c)

The Effect of the New Welding Code on Process Industries, and the Importance of Its Proper Application. F. G. SHERBONDY. *Journal American Welding Society*, Vol. 11, Feb. 1932, pages 28-29.
Paper presented at a joint meeting of the Metropolitan Sections of the A.S.M.E. and A.W.S. The universal approval that has been accorded welded construction is, according to the author, chiefly due to: (1) The long-felt need for vessels of superior construction, (2) The thoroughness with which various welding procedures have been worked out, (3) The coöperation of various organizations in unifying the various methods of welding into a universal code. This code may not always be understood and the proper class of welding may not always be specified. The author explains the classification of the A.S.M.E. code for welding pressure vessels and makes other pertinent comments on the subject of stress relieving. TEJ (11c)

Factors Affecting Welding of Alloy Steel. WILLIAM SPRARAGEN. *Electrical World*, Vol. 90, Jan. 23, 1932, pages 180-181.
Cr-Ni alloy steels are more readily welded than Cr alloys with Ni. Certain physical properties of the Cr-Ni alloys with less than 0.5% C must be considered in welding operations. Some possess but 1/3 of the heat conductivity of ordinary steels, while having an expansion coefficient about 50% greater than that of steel. For arc-welding of these corrosion-resisting steels a coated electrode is an absolute necessity. Reverse polarity is employed because the electrode is made the positive side and the work the negative terminal. Satisfactory welds have been produced with a C-arc shielded by a hydrogen atmosphere in many of the alloy steels. The gas mixture is usually 75% N and 25% H. WHB (11c)

Welding and the Heating, Piping and Air Conditioning Industry. L. B. SPAFFORD. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 8 pages.
The field of municipal and cross-country piping is reviewed and the materials now transported by piping compared with those transported by rail. The economic advantages, even necessity is discussed and shown how welding meets the requirements. Ha (11c)

Transformer Cases are Flash Welded. H. W. TOBY. *Welding*, Vol. 3, Jan. 1932, pages 27-29.
Description of transformer tank fabrication by the flash welding process. TEJ (11c)

Giving the Weld a Chance. G. E. THORNTON. *Journal American Welding Society*, Vol. 11, Feb. 1932, pages 9-10.
Article prepared as a report to the Fundamental Research Committee of the American Bureau of Welding. The usual test specimens used for determining the endurance of metals all contain a critical section at which the majority of the specimens break when tested in fatigue. If the weld is located at this critical section, the test does not show whether the weld is stronger or weaker than the stock metal in fatigue. The author suggests a constant strength specimen which abolishes the critical section and allows a stress to be applied which will be the same stress per unit of cross section at any point in the specimen. TEJ (11c)

Welding in Ship Building. (Schmelzschweissung im Schiffbau.) TEUBERT. *Werft, Reederei und Hafen*, Vol. 12, May 15, 1931, pages 164-166.
Report on a Discussion Meeting of the Schiffbautechnische Gesellschaft, Berlin, 1931, in connection with a lecture on "Construction Principles and Actual Accomplishment of Electro-Welding in Ship Building." EF (11c)

Welded Tips for High Speed Tools. THOMAS K. VINCENT. *Welding*, Vol. 3, Jan. 1932, pages 22-25.
Experiments in tipping high speed tools with cutting material by means of the electric arc and oxy-acetylene welding processes indicate that this method has a field in the manufacture of emergency or special tools. TEJ (11c)

Detailed description of specially designed dies used to make conduit units which were formerly made from bar stock in a screw machine. Present method reduces the cost of manufacture 60% and 2 sets of press tools produce 2700 parts/hr. RHP (12h)

The Construction and Uses of Typical Dies. Part VI. Edward Heller. *Metal Stampings,* Vol. 4, June 1931, pages 503-504, 512.

A discussion of press brake bending dies and the production of 90° bends with various types of "V" dies. The combination of several "V" dies in one die block is shown. JN (12h)

Cold Working (12j)

Cold Metal Working. E. P. Van Leuven. McGraw-Hill Book Company, New York, 1931. Cloth, 6¼ x 9¼ inches, 275 pages. Price $2.25.

A text book for manual training schools, with illustrated descriptions of such things as how to use a monkey wrench and how to make an ash tray. Good for its purpose, but not of metallurgical interest. H. W. Gillett (12j)-B-

The Influence of Cold Stretching on the Magnetic Susceptibility of Metals. (Zur Frage des Einflusses der Kaltreckung auf die magnetische Suszeptibilität der Metalle.) A. Kussmann & H. J. Seemann. *Naturwissenschaften,* Vol. 19, Apr. 3, 1931, page 309.

Experiments showed that the susceptibility of paramagnetic Al and of Ni-Cu-Zn alloys do not change on stretching. WHB (12j)

Machining Parts for Continental Aircraft Engines. Burnham Finney. *Iron Age,* Vol. 128, Dec. 3, 1931, pages 1418-1421.

Outlines steps in machining crankcase, crankshaft, connecting rods, pistons, cylinders and other parts of radial type aircraft engine at the plant of Continental Engine Co., Detroit, Mich. VSP (12j)

The Effect of Cold Work on the Physical Properties of Aluminum, with Special Reference to Its Specific Electrical Resistance. (English) G. Greenwood (University of Rochester). *Zeitschrift für Kristallographie,* Vol. 80, Nov. 1931, pages 481-494.

The specific electrical resistance of Al is increased by cold working and this increase can be removed again by annealing. It is removed completely by 10 min. annealing at 250° C. Annealing above this temperature causes another increase in the specific electric resistance owing probably to recrystallization of the metal accompanied by the production of cracks. Such an increase of other metals has been observed and explained by Credner (*Zeitschrift für physikalische Chemie,* Vol. 82, 1913, page 457). The breaking stress is also increased by cold working and decreased by annealing. Little decrease is obtained by annealing beyond 250° C. Cold working is done on the wire during such measurements and the breaking stresses of pieces of wire, which have once been broken, were found to have been increased except for those wires which have been annealed at temperatures above 250° C. Credner's hypothesis of crack production will also account for this. Cold drawn Al wire is known to possess a fibrous texture, in which the crystallites are arranged so that the (111) direction is parallel to the fibre axis. X-ray photographs showed that this texture is more marked, the more cold working there has been done on the wire. Recrystallization is seen to set in when the wires are annealed at about 250° C., although it is far from complete in wires annealed at 350° C. The fibrous texture is very persistent and can be detected in wires annealed at 350° C. Further cold working of these recrystallized wires breaks up the large grains and also produces a new fibrous texture, in which the particles are arranged with the (100) direction parallel to the fibre axis. The production of this new texture is more marked, the higher the temperature of annealing. X-ray photographs confirm previous observations that cold working of Al does not cause blurring of the doublets. Lattice distortions of the v.Arkel type (*Naturwissenschaften,* Vol. 13, 1925, page 662) are therefore not present, although distortions of the type discussed by Dehlinger (*Ahnalen der Physik,* Vol. 2, 1929, page 749) which might even approximate to the vitreous phase of Beilby, may occur. (*Proceedings Royal Society,* Vol. 72, 1903, pages 218, 226; Vol. 76, 1905, page 462; Vol. 79, 1907, page 463.) EF (12j)

Polishing & Grinding (12l)

Grinding Motor Parts to Close Tolerance, Cadillac Motor Car Co. *Abrasive Industry,* Vol. 12, Nov. 1931, pages 11-14.

The shafts are turned in special camshaft lathes. The set-up for grinding the cams is a special unit developed for the work. It is fitted with an alumina wheel 18 in. in diameter, with a ¾-in. face, 50 grit, shellac bond. WAT (12l)

Steel Mill Roll Finishing. H. J. Wills. *Abrasive Industry,* Vol. 12, Nov. 1931, pages 15-16.

Various phases of steel mill roll grinding are discussed in detail. WAT (12l)

Use of Diamonds. *Abrasive Industry,* Vol. 13, Jan. 1932, page 28.

An even, steady pressure will not injure a diamond, but sharp blows will split it and overheating will wear it rapidly. Reset diamonds will cut just as well as new ones. WAT (12l)

Grinding Methods for Motor Rims. *Abrasive Industry,* Vol. 13, Jan. 1932, pages 9-11.

Rubber-bonded wheels 14-18" in diameter are used at peripheral speed of 8000 ft./min. for grinding the outside of the welds. Somewhat smaller sizes are used for the inside work on the rims. WAT (12l)

CHEMICAL ANALYSIS (14)

The Use of Bromate in Volumetric Analysis. VI. The Determination of Iron Using Basic Mercuric Bromate. G. Frederick Smith & H. H. Bliss. *Journal American Chemical Society,* Vol. 53, Dec. 1931, pages 4291-4297.

Advantages of the bromate determination of iron as described in this paper make its use favorable as compared with the use of permanganate, dichromate or iodate and particular emphasis is directed to the fact that many organic materials, if present, do not interfere with the application of the method. MEH (14)

The Determination of Manganese in Cobalt Steel. (Die Bestimmung des Mangans in Kobaltstählen.) Fritz Spindeck. *Chemiker Zeitung,* Vol. 55, Sept. 19, 1931, page 723.

Dissolve 1-2 g. sample in HCl (sp. gr. 1.12) and oxidize with concentrated HNO_3. Evaporate to dryness, dissolve in HCl, dilute, boil and cool. Transfer to a 1 liter volumetric flask and precipitate Fe with ZnO. Dilute to the mark, mix and filter an aliquot part equal to 0.2 g. sample. Add 20 cc. HCl and Br water and allow to stand for 10 mins. Add an excess of NH_4OH, boil, filter and wash with hot H_2O. Dissolve the precipitate in $(NH_4)_2Fe(SO_4)_2 + H_2SO_4$, oxidize with HNO_3 and boil. Finish in the usual way by oxidizing with $AgNO_3$ and NH_4SO_4 and titrating with Na_3AsO_3. CEM (14)

Utilization of Micro-Analysis for the Investigation of Noble Metal Alloys. (Ueber Anwendung der Mikroanalyse zur Untersuchung von Edelmetallegierungen.) R. Strebinger. *Die Metallbörse,* Vol. 21, June 27, 1931, page 1206.

Recent use of Ni, Pd, Ag, Zn, Mn, etc., rendered the traditional streak method rather difficult. Strebinger and Holzer developed the following method: the scratch of the noble metal alloy is made on a carrier (glass) provided with a cavity and a rough surface by a sand blast. The base metals are extracted by dissolving media. The subsequent gravimetric, colorimetric and spectroscopic operations are outlined with reference to the different alloys. A paper before the 36th general meeting of the Deutsche Bunsengesellschaft für angewandte physikalische Chemie, Vienna, 1931. EF (14)

Manganese in Manganese Steel. J. H. Spillane. *Chemist-Analyst,* Vol. 20, Nov. 1931, page 10.

Dissolve 0.5 g. sample in 25 cc. 3:4 HNO_3 and boil till nitrous fumes are expelled. Add 50 to 60 cc. concentrated HNO_3 and 1-2 g. $KClO_3$; boil to half volume. Cool, add 200 cc. H_2O and a measured amount of H_2O_2 in excess. Titrate excess H_2O_2 with $KMnO_4$ and determine blank between H_2O_2 and $KMnO_4$. H_2O_2 solution consists of a 1 lb. bottle of H_2O_2, 275 cc. concentrated H_2SO_4 and 6000 cc. H_2O. CEM (14)

Determination of Tin in Irons and Steels. J. A. Scherrer. *Bureau of Standards Journal of Research,* Vol. 8, Feb. 1932, *Research Paper* 415, pages 309-320.

Apparently Sn is invariably a constituent of irons and steels, usually in amounts ranging from a few thousandths to a few hundredths of 1 per cent. The accurate determination of such small amounts of Sn is difficult, and methods that have previously been recommended are unsatisfactory. Practically all of these methods are based on the reduction of Sn to the divalent state, followed by oxidation to the quadrivalent state by means of a standard solution of iodine. The chief sources of errors in such methods lie in failure to remove other compounds that are reduced and oxidized, or in incomplete recovery of Sn when separations are attempted. As a result of the present study, a method has been developed in which Sn is separated from interfering elements, such as Cr, V, and W, by precipitation as sulphide in dilute HNO_3 solution, and then separated from elements, such as Cu and Mo, by precipitation with ammonium hydroxide. These treatments remove the elements that interfere, and the Sn is then reduced in a sulphuric-hydrochloric acid solution containing granulated lead, and afterwards oxidized as usual by means of a standard solution of iodine. With proper precautions, results that are accurate to 0.001% can be easily obtained. WAT (14)

The Determination of Lead in Slag. (Ueber Bleibestimmung in Schlacken.) Wilhelm Witter. *Chemiker Zeitung,* Vol. 55, July 18, 1931, page 550.

To separate from SiO_2, $BaSO_4$ and $CaSO_4$, use a 1 g. sample, add 50 cc. H_2O, boil, add 2 g. NH_4F and, with shaking, 20 cc. HCl (sp. gr. 1.1) and warm. Stir the residue. After 20 min., everything but the sulphides should be in solution. Add 5 cc. $KMnO_4$, boil for 10 mins., dilute to 250 cc. and pass in H_2S. Filter, wash with H_2O, Na_2S solution and H_2O. Dissolve the precipitate in HNO_3, add 10 cc. concentrated H_2SO_4 and evaporate to fumes. Dilute to 200 cc., boil, cool and filter. Dry and weigh $PbSO_4$ or dissolve in ammonium acetate and titrate with Mo solution. CEM (14)

Potentiometric Titrations in Zinc Chloride Solutions. (Potentiometrischen Titrierungen in Zinkchloridlösungen.) Milda Prytz. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 200, Sept. 12, 1931, pages 133-143.

Potentiometric titrations of metal salts can not very well be made with a hydrogen electrode; the author used with good results a Pt-plated Pt electrode which had to be freshly plated after each test. Method and test results of the molecular Zn concentration are described. Ha (14)

The Determination of Potassium with Perrhenium Acid. (Die Bestimmung von Kalium mittels Perrheniumsäure.) H. Tollert. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 204, Feb. 9, 1932, pages 140-142.

The great suitability and accuracy of this method is pointed out and analyses reproduced. 6 references. Ha (14)

The Sampling of White Metal Scrap with Particular Reference to American Methods. (Die Bemusterung von Altweissmetallen und Rückständen unter besonderer Berücksichtigung amerikanischer Usancen.) R. Thews. *Die Metallbörse,* Vol. 21, Apr. 11, 1931, pages 675-676; Apr. 18, 1931, pages 723-724; Apr. 25, 1931, pages 771-772.

Fifteen chief groups of tin bearing scraps, chips, residues, slags, etc. are specified, which are correspondingly subdivided as to the main element or to the origin. The author in particular refers to methods of specification familiar to the American scrap market. WHB+EF (14)

Chemical Analysis of Calcium in the Surface Layer of Eroded Gun Bores. N. Seliakoff & E. F. Alexeeff. *U. S. S. R. Scientific-Technical Department,* No. 401, *Transactions State Physical-Technical Laboratory,* No. 14, Moscow, 1930.

The presence of calcium in the surface layer of eroded gun bores was investigated by means of the M. Siegbahn's spectroscopic X-ray apparatus. Specimens 10 x 3 x 3 mm. taken from the surface layer of the eroded gun bores were analyzed and the presence of Ca was detected. When this was discovered, the microchemical and microanalytical analysis were made. The surface of the eroded gun was treated with the hydrochloric acid. A small quantity of solution was placed on the watch glass and a drop of concentrated sulphuric acid was added. The characteristic crystals of gypsum were observed under the microscope at 100 and 200 magnification. A sample taken from the eroded surface layer of bore near the breech and containing Cu was analyzed. Cu was dissolved in the nitric acid and it was determined that 1 mg. of Ca was present in 18 mg. of Cu; i.e., the content of Ca was about 5% of the Cu content. AIK (14)

Analysis of Sheet Zinc. Alfred Kundert. *Chemist Analyst,* Vol. 21, Mar. 1932, pages 10-14.

To a 30 g. sample add 25 cc. H_2O and 100 cc. concentrated HCl in 25 cc. portions. When action ceases add a few drops HNO_3 and heat until solution is complete. Separate Fe as basic acetate and titrate with $KMnO_4$. Add 15 cc. HCl to the filtrate, heat to boiling and add .5 g. powdered c.p. Al, stirring occasionally for 15 min. Filter rapidly and wash. Discard the filtrate containing the Zn. Wash the reduced metals from the filter into a beaker and dissolve in 3 cc. HNO_3 and a little HCl. Separate Pb as $PbSO_4$. Neutralize filtrate with NH_4OH and add 10 cc. 40% H_2SO_4 to every 100 cc. Precipitate Cu and Cd with H_2S and filter. Dissolve CdS in 1:3 HCl. Dissolve CuS in HCl + Br and determine colorimetrically. Add H_2SO_4 to Cd solution, evaporate to fumes, reprecipitate with H_2S, filter and dissolve in HCl, and titrate Cd with $K_4Fe(CN)_6$. In titrating Zn with diphenyl benzidine as an internal indicator the best Zn concentration is that which requires 10 cc. N/10 $K_4Fe(CN)_6$ for 100 cc. solution. The purple endpoint develops very slowly and requires shaking. CEM (14)

Experiences with the Magnetic Rapid Determination Method for Carbon by Malmberg's Karbometer. (Erfahrungen mit der magnetischen Schnellbestimmung des Kohlenstoffs mit dem Karbometer von Malmberg.) Heinz Kornfeld. *Archiv für Eisenhüttenwesen,* Vol. 5, Mar. 1932, pages 477-481.

Report 87 of Chemical Committee Verein deutscher Eisenhüttenleute. Compiled from data of 7 German plant laboratories. With exception of a single case, deviations in results by Karbometer method for C- and alloy-steels are so large as compared with results on similar samples by analytical method, that the Karbometer does not appear suitable as a means for determining C, to replace analytical method for accurate results. Plants, that previously worked with many preliminary samples and obtained highly accurate work, are not able to work nearly as accurately with Karbometer in spite of considerably shortened time of determination. By means of large number of Karbometric determinations, a certain quantitative picture of the course of steel melting may be drawn, even with the large inconsistencies. This is essential for such plants that formerly worked without a large number of preliminary samples, or, in the case where due to peculiarities of melting process the C content changed so rapidly that laboratory samples could not keep up with C changes. As an example of this, customary or pig iron ore method was used, by which in contrast to the Siemens-Martin scrap method, the C content is reduced very quickly and non-uniformly. In such cases there are practical advantages for certainty of melting process by use of Karbometer. It is then only necessary to estimate individual analyses with sufficient care in the calculation. Tables are given showing exact % deviation in results for 722 C-steel samples and 442 alloy-steel samples. The % errors for C-steels run from 5.3 to 53.1%; for alloy steels, from 23.7 to 38.4%. DTR (14)

A Convenient Method for the Separation of Cadmium and Bismuth in Low Melting Alloys. W. H. Keefe & I. L. Newell. *Chemist-Analyst,* Vol. 21, Mar. 1932, pages 8-10.

Dissolve sample in HNO_3 and filter off metastannic acid. Determine Pb as $PbSO_4$. To the filtrate add H_2SO_4 to bring up to 25 cc. H_2SO_4 in 100 cc. solution. Pass in H_2S, filter off Bi_2S_3 and wash with 1:3 H_2SO_4 saturated with H_2S. Dissolve Bi_2S_3 in HNO_3 and determine as BiOCl. Neutralize the filtrate with NH_4OH until just faintly acid and pass in H_2S. Filter off CdS, dissolve in HCl and determine as $CdSO_4$. CEM (14)

The Quantitative Determination of Lanthanum by Precipitation as Oxalate or as Hydroxide and the Higher Oxide Formation of Lanthanum. I. M. Kolthoff & Ruth Elmquist. *Journal American Chemical Society,* Vol. 53, Apr. 1931, pages 1225-1232.

A precise volumetric procedure is described for a determination of lanthanum as lanthanum oxalate. The oxalate can be estimated gravimetrically as oxide if ignited to constant weight in an electric furnace at 800° to 900°C. and weighed in a well-closed weighing bottle. Lanthanum may be precipitated also as hydroxide by adding the lanthanum solution slowly to an excess of base. Lanthanum oxide heated for long periods of time at white heat in air can be transformed into higher oxides. MEH (14)

Determination of Cadmium in Cadmium Cyanide Plating Solution. G. B. Hills. *Chemist-Analyst,* Vol. 21, Mar. 1932, pages 7-8.

To a 10 cc. sample of solution add 15 cc. 1:1 H_2SO_4 and evaporate to fumes, adding a little HNO_3 to oxidize organic matter. Dilute to 200 cc., add exactly 7 cc. HNO_3 and plate out Cu. Evaporate solution to fumes, dilute and add 5 cc. HCl. Neutralize with NH_4OH and filter off Fe. Neutralize filtrate with HCl and add 3 cc. excess. Heat to boiling and add 15 g. sodium acetate. Divide solution into 2 equal parts. Titrate one part while hot with standard $K_4Fe(CN)_6$ using 10% uranium acetate as outside indicator. Add second portion and complete titration. CEM (14)

Analytical Chemistry of Rhenium. (Beiträge zur analytischen Chemie des Rheniums.) W. Geilmann & F. Weibke. *Zeitschrift anorganische und allgemeine Chemie*, Vol. 195, Jan. 17, 1931, pages 289-308.

A method for the determination of rhenium by precipitating it as sulphide from a solution by hydrogen sulphide and determining it quantitatively after its oxidation to perrhenate as nitronperrhenate. Ha (14)

Quantitative Analysis of Alloys by X-Ray Spectroscopy. C. E. Eddy & T. H. Laby. *Journal of Physical Chemistry*, Vol. 35, Dec. 1931, pages 3635-3638.

The authors criticize conclusions arrived at by Torrey and Barrett (*Journal Physical Chemistry*, Vol. 35, 1931, page 1156), regarding the X-ray emission method of quantitative analysis, which they feel would prejudice the use of this method. They state that their experience is that correct analyses can be made, using this method, provided certain conditions are fulfilled. They proceed to discuss the technique of Torrey and Barrett, pointing out where improvements could be made which would lead to satisfactory results being obtained. Some attention is paid to the results of previous workers in this field, which serve to support their contentions. OWE (14)

The Rapid Colorimetric Estimation of Potassium. Earle R. Caley. *Journal American Chemical Society*, Vol. 53, Feb. 1931, pages 539-545.

This paper describes a rapid colorimetric method for estimating potassium depending upon its precipitation as potassium picrate by an alcoholic solution of picric acid, with the subsequent solution of the separated precipitate in water, yielding a highly-colored solution suitable for colorimetric comparison. MEH (14)

Electrolytic Determination of Copper in Steel. Lawrence Anderson & Hubert Swett. *Chemist-Analyst*, Vol. 20, Mar. 1931, pages 7-8.

A 5 g. sample is dissolved in 100 cc. 1:12 H_2SO_4 with gentle heat. The residue of Cu and carbides is filtered off, washed and dissolved in 10 cc. HNO_3, Sp. Gr. 1.20, and 20 cc. H_2O. The solution is filtered, 10 cc. 1:3 H_2SO_4 added, and electrolyzed at 2-3 volts and 3.5 amps. for 25-30 minutes. The cathode with Cu deposit is washed, dried in alcohol and weighed. CEM (14)

A New Test for Tin. Irwin Stone. *Chemist-Analyst*, Vol. 20, Mar. 1931, pages 6-7.

To the neutral or acid solution an equal volume concentrated HCl and a small quantity of granulated Zn are added. The solution is stirred with a test tube containing cold H_2O. Then the moistened portion of the test tube is held in the colorless part of a Bunsen flame. If Sn is present a characteristic blue flame is seen along the walls of the test tube. The test is very sensitive, detecting the presence of .0025 mg./cc. CEM (14)

The Spectrographic Assay of Some Alloys of Lead. D. M. Smith. *Engineer*, Vol. 152, Oct. 2, 1931, page 359.

Abstract of a paper read before the Institute of Metals, Zurich, Switzerland, Sept. 15, 1931. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 274. LFM (14)

The Determination of Sulphur in Foundry Cast Iron and Hematite (Die Bestimmung des Schwefels in Giessereiroheisen und Hämatit). G. Zenker. *Archiv für Eisenhüttenwesen*, Vol. 5, Aug. 1931, pages 101-103.

Report 84 of the Chemists' Committee of the Verein deutscher Eisenhüttenleute. After reviewing previous investigations of the chemists committee of the Verein deutscher Eisenhüttenleute on the determination of S in iron and steel and after giving a detailed description of the methods employed, the author summarizes the results of his investigations on the S determination of foundry pig iron and hematite carried on in collaboration with the laboratories of 6 German steel mills. It is shown that all the gravimetric and volumetric methods that are employed for the determination of S in pig iron give results that are in agreement. All the methods are suitable only when sufficient time is taken for the determination. If the time is limited, the O combustion method according to Holthaus is superior. GN (14)

Spectrum Analysis of Platinum Metals and Alloys (Spektralanalytische Untersuchungen an Platinmetallen und Legierungen). W. Gerlach & K. Ruthardt. *Siebert Festschrift*, 1931, pages 51-71.

Description of method with considerable detail on spectrum lines useful in determining presence of Cu, Fe, Ir, Ni, Os, Pd, Rh and Ru in Pt, and similar data for impurities in Ir and Rh. Quantitative methods of spectrum analysis for Ir and Rh in Pt are discussed and photometer curves of intensities shown. HWG (14)

An Oxidimetric Determination of Sodium. (Eine oxydimetrische Bestimmung des Natriums.) H. Gall & K. H. Heinig. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 202, Dec. 15, 1931, pages 154-160.

Description of the method by which it is possible to determine K as well as Na. Ha (14)

The Determination of Oxygen and Nitrogen in Iron and Steel by the Vacuum Fusion Method. (Ueber die Bestimmung von Sauerstoff und Stickstoff in Eisen und Stahl nach dem Vakuumschmelzverfahren.) W. Hessenbruch. *Stahl und Eisen*, Vol. 52, Jan. 28, 1932, page 87.

Discussion of Vacher & Jordan's vacuum fusion method for determining O and N in irons and steels, see *Bureau of Standards Journal of Research*, Vol. 7, 1931, page 375, and supplementary work of others. The writer confirms the work of Vacher and Jordan, using a modified gas analysis train. DTR (14)

The Present Ultimate Limit of Micro-Chemical Detection and Measurement. (Die heutigen Grenzen mikrochemischen Erkennens und Messens.) L. F. Hahn. *Die Metallbörse*, Vol. 21, Oct. 14, 1931, page 1854.

Appreciating the advances of X-ray spectroscopy and emission spectro-analysis on one hand, Hahn emphasizes the generally underestimated potentiality of micro-chemical methods on the other side and the speaker outlines the scope of utilization before the Verein Deutscher Chemiker, Vienna, 1931. EF (14)

Surface Effects on Assay Beads Caused by Metals of the Platinum Group. J. L. Byers (Michigan College of Mining and Technology). *American Institute Mining & Metallurgical Engineers, Preprint*, Feb. 1932, 17 pages.

Made Au beads weighing 500 mg. containing metals of the Pt group in concentrations of 0.02, 0.05, 0.1, 0.5, 1.0, 2.0, and 5.0%. The beads were made by wrapping the weighed quantities of Pt metals and Au in 20 g. of C. P. Pb foil and cupelling. Each bead was examined with a hand lens of 15X magnification, and the effects of the various metals on the appearance of the beads described. Micrographs (15X) of the beads are shown. The metals used were Ru, Rh, Pd, Os, Ir, Pt. A similar series of Ag-base beads was made and examined. X-ray diffraction patterns of a number of beads were also made. In both the Au and Ag beads the Pt metals in small quantities have a marked effect on the appearance of the beads, and it is suggested that all beads be examined in order that no source of Pt metals be overlooked. 3 references. JLG (14)

Application of X-Ray Spectroscopy for the Analysis of Ores and Metallurgical Products. (Über die Anwendung der Röntgenspektroskopie zur Analyse von Erzen und Hüttenprodukten.) W. Noddack. *Die Metallbörse*, Vol. 21, Oct. 17, 1931, page 1867.

Intensity of the spectral lines as a measure for the concentration. Accuracy, sensitivity, short time of measurement and small amount of sample necessary are stressed in this paper before the Verein deutscher Berg- und Hüttenleute, Berlin, 1931. EF (14)

The Sulphur and Soda Fusion. Archibald Craig. *Chemist-Analyst*, Vol. 21, Mar. 1932, pages 6-7.

Mix the sample of ore with 3 to 5 times its weight of a mixture of 10 parts S, 10 parts Na_2CO_3 and 14 parts K_2CO_3 and fuse in a covered Coors combustion capsule placed on a smaller crucible. For ores high in SiO_2 raise heat slowly at first and allow to cool as soon as the flux is completely liquid. After cooling leach the melt in cold water over night. Filter and wash and repeat the fusion of the insoluble residue. The method is useful in the analysis of mixed ores, for the determination of impurities in Sb and Sn ores and the determination of Sb and Pb in Cu ores. The fusion can also be used in bronze analysis for the purification of SnO_2 after HNO_3 treatment. CEM (14)

Diphenylamine as Indicator in the Determination of Iron in Silicates. C. J. Schollenberger. *Journal American Chemical Society*, Vol. 53, Jan. 1931, pages 88-89.

In presence of sufficient hydrofluoric acid in proportion to H_2SO_4 or HCl, diphenylamine is an excellent indicator for the dichromate titration of a solution containing ferrous iron. MEH (14)

Quantitative Spectrum Analyses for Tin in Lead, and Ti, Si and Fe in Commercially Pure Aluminum. (Beiträge zur quantitativen Emissions-Spektralanalyse unter besonderer Berücksichtigung der quantitativen Bestimmung von Zinn in Blei und der quantitativen Erfassung geringer Titan-Silicium- und Eisengehalte in Rein-Aluminium.) Josef Clermont (Technischen Hochschule zu Aachen). Dissertation, 1932. J. F. Bergmann, Munich, 1931. Paper, 6 x 9¼ inches, 50 pages. *Zeitschrift für analytische Chemie*, Vol. 86, No. 5/6, 1931, pages 191-216; No. 7/8, 1931, pages 271-288.

Used spark spectra with Zeiss spectrograph with 9x12 cm. plates. The internal standard method of estimation or a modification was used. In this method the intensity of lines of the low concentration element are matched with lines from the base element. The intensities of the lines were determined by inspection or by measuring the height of lines made with a rotating logarithmic sector. A table is given by which the amount of Sn in Pb can be determined if the relative intensities of lines are found. As Al did not have well suited low intensity lines by which Ti, Si or Fe lines could be compared, the lines of these impurities were compared with a Cu spectrum taken on the same plate. Again, tables are given from which the quantities of impurities can be determined after the necessary spectral lines have been studied. This method of analyzing Al was found to be reliable and satisfactory. It is much quicker than classical methods, and is also cheaper. 28 references. JLG (14)

Determination of Phosphorus in Alloy Steels Insoluble in Dilute HNO_3. A. B. Cargill. *Chemist-Analyst*, Vol. 21, Mar. 1932, page 5.

Dissolve 2 g. sample in 30 cc. HNO_3 and 20 cc. HCl and add 2 cc. HF. Evaporate to dryness and bake 15 min. Add 20 cc. concentrated HNO_3, and after the residue has dissolved almost neutralize with 1:1 NH_4OH. Precipitate P with ammonium molybdate and finish as usual. If V is present add 10 cc. N/10 $(NH_4)_2Fe(SO_4)_2$ before neutralizing. The method is especially useful for stainless steels. CEM (14)

An Outline of Microchemistry (1). Janet W. Brown. *Canadian Chemistry & Metallurgy*, Vol. 16, Jan. 1932, pages 6-8; Feb. 1932, pages 31-33.

A summary of general methods of microchemical analysis. A few "spot" tests and capillary methods are outlined. The value of microchemical methods as time and material savers is pointed out. The possibility of duplicating larger scale tests on very small quantities of material is pointed out. Thus melting point, boiling point, sublimation point, and chemical reactions and purifications may be adapted to micro-scale work. Adaptions to gravimetric analysis, volumetric analysis, micro-combustion and micro-Kjeldahl determinations are pointed out. A good English and German bibliography is appended. WHB (14)

The Determination of Strontium in the Mineral and Ore Analysis. (Ueber die Bestimmung des Strontiums in der Mineral-und Gesteinsanalyse.) W. Noll. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 199, July 21, 1931, pages 193-207.

The usual methods of determining Sr and its separation from Ba and Ca are discussed and their inaccuracies described. Separation with HNO_3 gives good results. Strontium (R = 1.27 A.U.) can be precipitated quantitatively with Pb (R = 1.32 A.U.) as chromate; a separation from Ca is not possible in this manner. Ha (14)

Powder "Bruinella" for Elimination of Sulphur, Slag and Pipes. (Entschwefelungs- Entschlackungs- und Entlunkerungspulver "Bruinella.") R. BERGER. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Apr. 17, 1932, pages 159-160.

The new powder to be added to cast iron for the elimination of sulphur, slag and pipes is claimed to have many advantages. It is added while the molten iron is tapped in the ladle and increases its temperature and fluidity. Experiments showed that it decreases the S content of the iron by about 40%, thus making the iron more machinable. Iron treated with the powder is denser and the powder reduces the tendency for the formation of pipes. GN (22)

The Sweeping of Oval Molds. (Le Troussage de Moules Ovales.) DELCROISETTE. *Revue Fonderie Moderne*, Vol. 26, Jan. 25, 1932, pages 30-32.

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Load and Temperature Stresses in Circular Flat Plates. H. L. M'Broom & C. M. Moir. *Journal Royal Technical College* (Glasgow), Vol. 2, Jan. 1932, pages 665-679.

A paper in a previous issue (1930, page 230) of the above journal dealt, generally, with the close similarity of the equations for the direct stresses and the bending stresses in circular plates of uniform thickness. The parallelism of the stress equations was established for both loading and temperature conditions with the aim of providing 2 sets of general results in strict correspondence. The present work deals with several unusual flat plate problems, trying to simulate actual conditions as nearly as possible. The research is almost entirely mathematical. It considers (1) a plate with uniform lateral pressure and a temperature drop through the metal varying with radius; (2) a plate with a central zone of uniform pressure and temperature drop, and an outer zone with radial variation of both; (3) a plate loaded laterally with uniform pressure with either free or fixed periphery and carried on a ring support placed for minimum stresses; and (4) a rotating disc with lateral pressure and rotational stresses and with transverse and radial heat flows. WAT (29)

Temperature Stresses in Non-Circular Drums. H. L. M'Broom & C. M. Moir. *Journal Royal Technical College* (Glasgow), Vol. 2, Jan. 1932, pages 657-665.

Presents a short theoretical investigation of the stresses in the walls of non-circular thin drums due to variations of temperature throughout the material, and constitutes an extension of work previously (1931, Vol. 2, page 427) published in this journal. Allowance is made for varying flexural rigidly in the walls. A brief consideration of certain special cases which include most practical types is appended, together with examples demonstrating the application of the results to numerical cases. WAT (29)

High Temperature Strength of Alloy and Plain Carbon Cast Steel. (Warmfestigkeit von legiertem und unlegiertem Stahlguss.) Karl Heinz Müller & Eugen Piwowarsky. *Archiv für Eisenhüttenwesen*, Vol. 5, Mar. 1932, pages 483-485.

The notch toughness, hardness, tensile strength of 8 steels were studied in the temperature range of 0° to 500° C. The composition and annealing temperature of the 8 samples are given in the following table:

Steel No.	Chemical Composition, Percent[1] C	Si	Mn	P	Misc.	Annealing Temp. ° C.[2]
1329	0.12	0.70	0.72	0.036	......	930

1682	0.40	0.47	0.72	0.017	2.36 Cr, 0.40 Mo, 0.12 V.	930[3]

[1]S present in traces only.
[2]Cooling in furnace.
[3]Tempered in air, annealed for 2 hours at 600° C.

The tensile strength, hardness and endurance strength increased appreciably with increasing C content. Addition of Mn increased these properties slightly, while Cr, especially in combination with W, or still more noticeably with Ni, produced appreciable increases in these properties. The reverse of this was true with notch toughness. DTR (29)

The 18-8 Iron-Chromium-Nickel Alloy with Particular Reference to Its Characteristics for Cracking Coil Service. H. D. Newell. *Preprint American Petroleum Institute*, Apr. 1931, 20 pages.

The characteristics of the 18-8 alloy are mainly dealt with. However, some comparisons of the creep strength of 18-8, 4-6% Cr and 2 C steels, 0.08 and 0.20% C, are made up to temperatures of 1350° F. Loads producing creep of 1% in 10,000 and 1% in 100,000 hours for these alloys are given. The precautions, limitations and disadvantages of the 18-8 alloy as applied to tube service are discussed in detail. Failure of alloy cracking tubes in service, however, have only been about 20 in number of all the tubes used. There is a considerable tonnage of the 4-6% Cr steel now being used by the oil industry and the straight 4-6% Cr type has been superseded by steels containing either 0.75-1.25% W or 0.40-0.65% Mo with the usual 4-6% Cr. Steels containing 4-6% Cr without any alloying additions have no advantage over C steel, insofar as creep strength is concerned. In the 18-8 alloy, while the higher C content will stabilize the austenite, it increases the chance of chromium carbide being precipitated to the grain boundaries, causing local impoverishment in Cr content, which means less corrosion resistance and more tendency for creep at high temperatures. The attainment of this knowledge is said to have been the main accomplishment of the past year regarding the 18-8 alloy. Apparently, plain C steel or the 4-6% Cr steel tube will be the most used for the present. The 18-8 alloy finds a useful field where higher temperatures and pressures prevail, together with severe corrosive conditions. WAT (29)

Tensile Testing of Bars and Wires at Low Temperatures. (Festigkeitsprüfungen an Stangen und Drähten bei tiefen Temperaturen.) F. Pester. *Zeitschrift für Metallkunde*, Vol. 24, May 1932, pages 115-119.

The tensile properties of Cu, bronze, Al, "Aldrey," and steel were studied at temperatures down to -60° C. A new testing machine for the determination of bending properties of wires at low temperatures is described. Curves are given showing the tensile properties of the alloys studied against temperature. In general the strength increases linearly with decreasing temperature for rolled or drawn materials. Elongation and reduction in area, however, do not show a uniform behavior. The bending capacity of Cu, bronze and Al increased with a temperature decrease to -60° C., while that of Aldrey did not change much. With steel the number of bends was a maximum at a temperature of -20° C. RFM (29)

The Wrought Austenitic Alloys (at High Temperatures). R. H. Aborn & Edgan C. Bain (United States Steel Corporation). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 466-494.

For abstract of paper see *Metals & Alloys*, Vol. 2, Dec. 1931, page 324. In the discussion short-time tensile properties up to 1400° F. are reported for an austenitic Mn steel containing 0.47% C and 14.77% Mn. Its maximum tensile strength (130,000 lbs./in.^{2}) and proportional limit (35,000 lbs./in.^{2}) occur in the neighborhood of 200° F. Between 300° and 400° F. the elongation is more than 80%. There is a possibility that this type of steel could be machined and drilled if the temperature rise local to the tool could be maintained below the slight increase (200° F.) required to produce maximum toughening. The Republic Steel Company states that the widespread use of the 18-8 Cr-Ni type of steel, irrespective of its elevated temperature characteristics and the excellent resistance offered to corrosion, is probably due most of all to the ease with which it may be fabricated. L. Cameron & Son, Ltd., Sheffield, England, produces a steel containing 30% Ni, 11 Cr, 59 Fe and with as little C as possible. This alloy is readily workable either hot or cold. Short-time tensile properties presented show a strength of 52,000 lbs./in.^{2} and 20,000 lbs./in.^{2} and a yield point of 40,000 lbs./in.^{2} and 18,000 lbs./in.^{2} at 1290° and 1650° F. respectively. Increasing the Cr content to 19% results in a breaking strength of 47,000 lbs./in.^{2} at 1470° F. WAT (29)

The Strength at High Temperatures of Six Steels and Three Non-Ferrous Metals. *Department of Scientific & Industrial Research, Engineering Research, Special Report* No. 18, 44 pages. Price 9d.

The report describes the results of work, undertaken for the most part at the request of Synthetic Ammonia & Nitrates, Ltd., upon the examination of the short-time tensile and creep properties between 300° and 600° C. of 6 heat-treated steels, namely, 0.5% C steel, 3% Ni steel, Ni-Cr steel, Cr-V steel, stainless steel and staybrite, and also the properties between 150° and 500° C. of phosphor bronze, duralumin and 60:40 brass. Numerous charts are given, showing the variation with temperature of the ultimate stress, limit of proportionality, proof stresses and the stress-temperature relations for definite rates of creep extending to 10^{-5} in./in./day. Full details of the creep tests are given and the relative tensile and creep properties of the materials are discussed. The results obtained provide information permitting the estimation of suitable working stresses at different temperatures. (29)

Aluminum Brass, A New Valuable Alloy. (Aluminium-Messing, eine neue, wertvolle Legierung.) *Aluminum*, Vol. 14, Jan. 31, 1932, page 6.

The addition of even small amounts of Al (0.1%) prevents the evaporation of Zn entirely and increases the resistance to oxidation at high temperature. The material is especially useful for condenser tubes. A composition of 70% Cu, 30 Zn with 2% Al does not show any surface dezincification and oxidation at 775° C. Ha (29)

Torsion Testing Machine. (Machine d'essai a la torsion). R. Guillery. *Revue de Métallurgie*, Vol. 29, Jan. 1932, pages 52-64.

Torsion testing machine for wires is described. It is particularly suitable for the determination of the torsional strength at elevated temperatures. The torque is created by an oil damped spring. Means are provided for automatic registering of the torque, angle of torsion and number of revolutions. JDG (29)

Strength of Material and Future Development of the Steam Process. (Materialfestigkeit und weitere Entwicklung des Dampfprozesses.) K. Baumann. *Die Röhrenindustrie*, Vol. 24, Jan. 1, 1931, pages 3-5; Jan. 15, 1931, pages 16-18; Feb. 12, 1931, pages 51-53; Mar. 12, 1931, pages 63-65.

Tabulated data on 28 recently erected power plants, show the steady increase of pressure and steam temperature. The phenomenon of creep and the failure of Hooke's law at elevated temperatures is discussed. The minimum creep velocity of bolts is computed, the limit being 10^{-8} for 2 year's service. Fortunately no creep occurs in the longitudinal direction. The maximum creep velocity for different power plant parts is given as follows: steam pipes with welded joints and boiler tubes, 10^{-7}; superheater units, 10^{-6}-10^{-5}; turbine blades, 10^{-6}; screwed-on flanges of turbine housings, 10^{-8}. The properties of different materials at elevated temperatures are dealt with. The data are presented in 4 sets of curves, referring to a low carbon (0.15%) steel and to a Cr-Ni-Mo steel. The admissible stresses in steam pipes at high pressures and elevated temperatures, the stresses in tubes which transfer heat, the construction of tube flanges and their imperviousness and the behavior of flanges, when being put into operation are discussed. EF (29)

Apparatus for Long Period Temperature-Stress Tests on Metals. W. H. Hatfield, G. Stanfield, J. Woolman & N. B. McGregor. *Journal of Scientific Instruments*, Vol. 9, May 1932, pages 150-153.

An apparatus for high temperature mechanical testing suitable for accurate determination of creep and allied effects is described and illustrated, and the order of sensitivity indicated. The apparatus includes a sensitive optical extensometer reading to 0.3 millionths in./in. The test piece has an 8" gage length. A method of controlling the temperature of the specimen to ± ¼° C. in an electric resistance furnace makes use of a Pt resistance coil placed in the furnace, and which forms part of a Wheatstone bridge and through a control indicator and relay operates the adjustment of the furnace current to compensate for minor fluctuations from various causes. The loading device is a simple lever system equipped with knife edges, the load being applied by means of a screw placed under the 20:1 lever arm. WAT (29)

Investigation of the Hardness of Copper. I. E. Gorshkov & V. O. Gagen-Torn. *Metallurg* (Russia), Vol. 6, 1931, pages 173-176.

The change in the hardness of Cu at high temperatures and its relation to the O content were investigated. The hardness was found to increase proportionally with the O content within the limits of 0-0.28% O_2, corresponding to 0-2.5% Cu_2O. The temperature has a more marked effect than the O content on the hardness. (29)

The Cold Treatment of Certain Alloy Steels. G. V. Luerssen & O. V. Greene. *Transactions American Society for Steel Treating*, Vol. 19, Apr. 1932, pages 501-552.
See *Metals & Alloys*, Vol. 3, May 1932, page MA 150. WLC (29)

Symposium on Effect of Temperature on Metals. A.S.T.M. and A.S.M.E., Philadelphia and New York, 1932. Cloth, 6 x 9¼ inches, 829 pages. Price $6.00.
There is probably little realization of the tremendous amount of study of high temperature properties, which is going on at the present time. It requires a symposium such as the one sponsored by the A. S. T. M. and the A. S. M. E. to give us some realization of the scope of the work.
A review of such a symposium encounters the same difficulties as the review of an encyclopedia, and so we must mention every article in the symposium, lest we fail to convey the correct impression as to the multiplicity of subjects.
The authors and their subjects are as follows:
Kerr, on power plant industry; high temperature properties needed in immediate future; mostly tubes also weld metal. Allen, on Steam turbine materials; .01% per year creep allowable; much 12% Cr in use. Martin, on Steam piping; pipes and fittings—3% creep in 200,000 hours (22 years) allowable = .14% per year. Dixon, on Oil industry; creep stress; thermal conductivity, coefficient of expansion, corrosion; *indications of impending failure* (swelling). Rhodes, on Chemical industries; attack by H_2SO_4, HCl, alkali, tar distillates, H_2. Woodson, on Ferrous metal industries; resistors, japanning ovens, etc.; heat treating furnace parts; emphasize design of parts. Brown, on Non-ferrous industries; (roasting, smelting, refining). Roasting furnaces, in retorts; lead smelting; flue dust recovery. Boegehold and Johnson, on Automotive industry; auto and Diesel engines; pistons, valves, cylinders, bearings; aircraft likewise. Williams, on Ceramic industry; firing in kilns; firing refractories; china ware; vitreous enamel; glass industry. Bailey, Dickenson, Inglis and Pearson, on Trend in Great Britain; power plant, design, effect of creep on calculations; individual elements, Cr, Ni, Mo. Chevenard, on Properties at elevated temperatures; studies of metal deformation in regard to internal friction and viscous deformation.
Anderson, on Zinc alloys; hot mechanical properties of rolled, cast, extruded zinc and of zinc alloys with Cd, Cu, Sn, Al, Mg. Templin and Paul, on Aluminum and Magnesium; effect of alloying additions on strengths of Al and Mg. Darby, on Bearing metals; mechanical properties vs. temperature, and factors affecting usefulness and life. Price, on Cooper and its alloys; mechanical properties vs. temperatures; discussion by Bassett, also others. Spooner and Foley, on Creep of steels; compilation of data on ordinary and low alloy steels. Bull, on Cast steels; cast carbon and low alloy, above and below room temperature. Bolton and Bornstein, on Gray iron and Malleable iron; properties, structure and a discussion of "growth." Aborn and Bain, on Wrought austenitic alloys; mechanical, structural and corrosion characteristics of the wrought austenitic Cr-Ni steels. Pilling and Worthington, on Iron-chromium-nickel alloys; effect of variations in Ni and Cr on short time tests and long time tests for strength; also oxidation resistance. Crawford and Worthington, on Nickel alloys; high temperature mechanical properties of nickel and alloys of nickel. MacQuigg, on High chromium steels; mechanical and corrosion properties of chromium irons. Swanger, on Rare metals; silver, gold, tantalum, platinum and their groups. Harder, on Nitrided alloys; mechanical and other high-temperature properties of nitrided steels. Russell, on Low-temperatures; mechanical properties at medium low and very low temperatures. Mochel, on Thermal expansion; expansion values, their applications, and a very complete tabulation for a long list of materials. VanDusen, on Thermal conductivity; consideration of conditions in practice. Miss McCombs, Bibliography; 615 references, most of these in the last three years.
One of the first impressions on reading the book is that of being face to face with a new aspect of industry, one that is suddenly becoming of very great importance, and one in which the data are only beginning to be satisfactory.
Most of the authors published test data and gave the results of their own experience. A number of authors went further, and ascertained opinions throughout their branch of the industry. These opinions were obtained through questionnaires and are exceedingly valuable because of the different views expressed.
The value of the papers is also enhanced by the active discussion aroused, as for example in the case of Dixon on Oil Industry, Boegehold and Johnson on Automotive Industry, Price on Copper and Its Alloys, and Spooner and Foley on Creep of Steels.
Impressive also is Miss McCombs' list of 615 articles related to these subjects, a large proportion of these having appeared in the past few years.
With such a wealth of material it seems captious to criticize. From the practical point of view, however, it might be useful in a future symposium to give more data on actual service records. Some such service records are given, and these assuredly enhance the value of the book.
From the theoretical and design standpoint, it is unfortunate that we have resorted often to short time tests, when the information desired is in reality creep. Since the nature of the deformation in creep is quite different from deformation in rapid loading, it will be necessary to have actual creep data before much reliance can be placed on high temperature tests. We may as well face this condition, and accept the fact that we must carry out the tests over a long period of time.
While it is always possible to point out shortcomings, nevertheless the fact remains that the book under discussion is not only an outstanding contribution to the industry but is also indispensable to any one interested in the many phases of high temperature service.
M. A. Grossman (29) -B-

Metallurgical Investigations. *Iron & Coal Trades Review*, Vol. 124, Jan. 15, 1932, page 82.
Progress in research on creep phenomena in steel ingots and castings, cracking of boiler plates and inclusions in steel is briefly reviewed. Ha (29)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

The Parkerizing and Bonderizing Rust-Proofing Processes. *Engineering*, Vol. 132, Oct. 9, 1931, page 475.
Describes processes as carried out in the plant of The Pyrene Company, Ltd. at Brentford, Middlesex, England. Parkerizing is a process in which the surfaces of Fe and steel articles are converted by chemical means into phosphates which are insoluble in water and permanent in air. The solution used is made from "Parco" powder consisting mainly of Mn phosphate. The coating is less than 0.0002" thick. The Bonderizing process is similar, the solution being made from a powder consisting of Mn phosphate with a small amount of Cu salt. LFM (32)

Painting of Iron and Copper Sheets. (La Peinture sur Tole de Fer et sur Toles de Cuivre.) J. Meyral. *Cuivre et Laiton*, Vol. 5, Mar. 15, 1932, page 117.
The replacement of Fe sheets by Cu sheets is recommended as even a coat of paint is not an absolute protection from rust; the self-oxidizing of Cu on the other hand, is, with or without paint, absolute protection in Cu. Ha (32)

A Gas-Heated Japanning Oven. Applying the Finish to Electrical Equipment. *Gas World*, Industrial Gas Supplement, Vol. 96, Apr. 16, 1932, pages 15-16.
Abstracts an article by W. J. Miskella in "Industrial Gas," which describes the particulars of a gas-heated oven installation for japanning electrical equipment. MAB (32)

Aluminum Paint in Apparatus Construction. (Aluminiumanstriche im Apparatebau.) E. Becker. *Apparatebau*, Vol. 44, Apr. 1, 1932, pages 59-60.
Al paints for apparatus offer the following advantages: low weight, low capacity of heat radiation (it amounts at 40° C. only to about 30% of the internal heat of a black body and, therefore, makes it suitable as paint for boilers, furnaces, etc.) high capacity of reflection (about 60-75% of the impinging light is reflected) high resistivity to sulphur compounds, high resistivity to the effects of sun beams. Al paint is suitable for any material, such as steel, wood, cement, pasteboard, etc. The preparation of Al paints and the methods of painting are described. GN (32)

Gypsum as Insulator for Structural Steel. Henry Schwein. *Iron & Steel of Canada*, Vol. 15, Mar. 1932, page 25.
Deals with the subject of fire test on gypsum and gypsum products and the value of such products as protection for structural steel against high temperatures. Tests conducted by Hull and reported in Technical Paper No. 130 (Bureau of Standards) are dealt with in some detail, as are also the tests conducted in 1922 at Columbia University on floor construction composed of precast gypsum floor slabs supported on 10-inch, 15-pound channels. OWE (32)

Evaluation of Clear Nitrocellulose Metal Lacquers. G. C. Shakour & L. W. Munchmeyer (du Pont Co.). *Metals & Alloys*, Vol. 2, Dec. 1931, pages 331-336.
4 types of clear metal lacquers are briefly discussed, phenol condensation lacquers, lacquers from condensation products of polyhydric alcohols and polybasic acids, gum lacquers and nitrocellulose lacquers. Tests for various types of defects occurring in lacquered metal work are discussed. Corrosion tests of lacquer films, evaluation of such properties as adhesion, hardness and flexibility are described. Rating of lacquers is effected by dividing into 3 groups: (a) ratable properties, those of primary importance for the use in question, properly weighted from 0 to 100, (b) minimum requirements, of secondary importance but must be had to a certain degree; (c) economic factor. An example of the system of rating applied to 2 lacquers is shown. The essential detail in successful lacquering is cleanliness; short cuts around it are apt to be costly. WLC (32)

The Japanning of Steel. William J. Miskella. *Metals & Alloys*, Vol. 2, Dec. 1931, pages 318-323.
Japanning is a metal finishing process involving the application of a mineral substance similar to asphalt in proper thinner with a black pigment and finally drying by baking at a temperature in excess of 325° F. Such a coating is very long lived and resistant and is cheapest known surface protection. Modifications of japan by the addition of varnish gums, various applications, methods of application and baking are described. WLC (32)

What Should We Pay for Pipe Coating. H. B. Truett (Associated Oil Co.). *Oil & Gas Journal*, Vol. 30, June 4, 1931, pages T-45, T-47.
The economics of pipe line protection is discussed, an equation formulated and curves given. VVK (32)

Some Methods of Pipe Line Protection. *Petroleum World*, London, Vol. 28, May 1931, pages 164-170.
A coöperative group of coating manufacturers offer a few worthwhile suggestions. Proper application of pipe coatings is most important in obtaining lasting results. (32)

Report on the Results of Series Tests on White Paint Coatings with Reference to Atmospheric Stability and Protective Effect against Corrosion. II. Part: Results of 2½ and 3 Years Tests. (Bericht über die Ergebnisse einer Reihenuntersuchung von Weissfarben-Aussenanstrichen auf Wetterbeständigkeit und Rostschutzvermögen. XII. Teil: Ergebnisse nach 2½ und 3-jähriger Versuchsdauer.) E. Maass & R. Kempf. *Korrosion und Metallschutz*, Vol. 7, Dec. 1931, pages 293-302.
The second and third set of samples previously described were exposed to atmospheric destruction during a testing period extended to 2½ and 3 years respectively. Generally speaking, the coatings on Fe proved to be in a materially better condition than those on wood, while the paint coatings on the brick walls was about between the Fe and wood paint coatings. The testing results are presented in tabular form. The order of merit of the different paint coatings employed on Fe may be reproduced. The following groups could be clearly distinguished: (1) Pure lead chromate, lead white, sulpho-lead white, zinc white and compositions of lead chromate/lithopone and of zinc white/Titanox B. (2) Less favorable: pure titanium dioxide and mixtures of lead white/lithopone, sulfo-lead white/lithopone and partly zinc white/lithopone. (3) The lowest grade of paint coatings proved to be all the 3 kinds of pure lithopone and part of the mixtures zinc white/lithopone. EF (32)

Experimental Tests on Gold Ore from the Beardmore Gold Mines, Ltd., Port Arthur Area, Ontario. J. S. Godard. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 11-17.

Amalgamation of an ore essaying Au 0.93 oz. and Ag 0.13 oz./ton and Pb 0.03%, Zn 0.02%, Cu 0.02%, Fe 4.12%, As 1.02% and insoluble 79.51% gave recoveries of Au of 57% at 8% plus 48 mesh and 79% at 5% plus 100 mesh. Flotation with K Xanthate 0.15 lb. and pine oil 0.08 lb./ton after ball milling with coal tar creosote 0.20 lb./ton gave 83.6% of the ing gave 13.7% more in a product containing 2.46 oz., a total Au in a concentrate assaying 9.58 oz./ton; tabling the tailing gave 13.7% more in a product containing 2.46 oz., a total of 97.3% in a 6.79 oz. product. Cyanidation of minus 100 mesh ore gave recoveries of 97-98.5% with consumption of KCN of 0.53-0.61 lb. and CaO of 5.3-6.9 lb./ton. AHE (33)

The Development of Processes for the Treatment of Crude Ore, Accumulated Dumps of Tailing and Slime at Broken Hill, New South Wales. Members of the Broken Hill Branch of the Australasian Institute of Mining and Metallurgy. *Proceedings Australasian Institute of Mining and Metallurgy* No. 80, 1930, pages 379-444.

The development of the various processes which have led up to the metallurgical practice of the present day at Broken Hill are described. These include blast furnacing, gravity concentration, magnetic separation, the Potter process (use of hot acidulated flotation solutions), Delprat process (flotation using salt cake), the Cattermole process (aggregation in water suspension of selectively oiled particles), the DeBavay process (film flotation), the Elmore vacuum process (aeration during flotation by release of dissolved gases by vacuum), the minerals separation process (flotation-refinement of Cattermole process), Murex magnetic process (differential application of magnetic coating), Henderson's process for oxidized Pb, and differential flotation [Horwood, Lyster, Bradford ($NaCl-H_2SO_4$), Lowry and Greenway, Owen and Bradford ($CuSO_4$) processes.] Present practice with reagent consumption, assays and recoveries for each company is presented and trends in the field are discussed. AHE (33)

Laboratory Concentration of Wabana Iron Ore. T. W. Hardy & H. H. Bleakney. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 195-198.

Even after grinding to minus 200 mesh, 41.6% of the insoluble and 42.8% of the P are still locked with the Fe and are retained in concentration, making it too low grade for sponge Fe. AHE (33)

The Treatment of Gold Ores from the English Brook Area, Rice Lake District, Manitoba. C. S. Parsons. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 164-169.

A siliceous ore containing a small amount of sulphide and Au, principally native, from 3 claims, assaying 0.81 oz., 0.77 oz., and 0.28 oz. of Au/ton gave recoveries of 71.6%, 92.2% and 67.9% by amalgamation. Cyanidation recovered 96.3%, 96.1% and 96.5% with normal reagent consumption. Flotation concentrates carried 70.7%, 85.1% and 71.8% of the Au. Amalgamation followed by flotation recovered 97.7%, 93.9% and 93.9%. Cyanidation of these concentrates gave 92% recovery with normal reagent consumption. AHE (33)

Eagle-Picher's Central Milling Project in the Tri-State District. R. J. Stroup. *Advance Paper, American Zinc Institute*, Apr. 1932, 11 pages.

The mill hopper at each change from one ore to the other is emptied and the concentrates produced from each tract are placed in separate bins. Automatic devices are arranged to keep the ores entirely separate and prevent filling the hoppers if they are not emptied. The advantages of a central milling plant over scattered units are better recovery due to better equipment and better supervision than at a large number of units, continuous operation and uniform feed; lower milling costs because of the large tonnage handled per man, lower power costs and lower costs of repairs and supplies; better control of grade of concentrate produced, elimination of duplication costs and reduction of overhead costs; and the investment is less than for individual units. Ha (33)

Experimental Tests on Gold Ore from the Arrowhead Consolidated Mines, Ltd., Joannes Township, Rouyn Area, Quebec. J. S. Godard. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 24-29.

A Au ore containing 1.21 oz./ton was floated and the tailing tabled, amalgamated and the tailing floated, amalgamated at various sizes, and cyanide at various sizes. At minus 100 mesh 98-99% can be recovered by cyanidation with consumption of KCN of 0.4-0.5 lb. and of CaO of 3.5-4.4 lb./ton. AHE (33)

Milling Methods and Costs at the Lead Concentrator of the Hecla Mining Co., Gem, Idaho. W. L. Zeigler. *United States Bureau of Mines, Information Circular* No. 6600, Apr. 1932, 16 pages.

A milling ore containing galena and marmatite averaged (1930) Pb 8.7%, Zn 1.2%, Fe 7.1%, insoluble 68.8%, and Ag 4.77 oz./ton is treated by combined gravity and flotation methods. The jig concentrate assayed Pb 52.02%, Zn 3.5%, and Ag 27.09 oz./ton and contained 65.8% of the Pb, 40.1% of the Zn and 62.5% of the Ag. Flotation of the reground jig middling (Pb 6.3%, Zn 3.0% and Ag 3.0 oz./ton), primary slimes and original minus 16 mesh ore using soda ash 0.1 lb., $ZnSO_4$ 0.3 lb., cresylic acid 0.1 lb., aerofloat (25%) 0.03 lb./ton gave a Pb concentrate assaying Pb 61.3%, Zn 5.0%, and Ag 34.6 oz./ton, containing 25.9% of the Pb, 16.6% of the Zn and 26.9% of the Ag. Flotation of the tailing with $CuSO_4$ 0.3 lb., aerofloat (25%) 0.05 lb. and Barrett No. 4 oil 0.05 lb./ton gave a Zn concentrate assaying Pb 9.3%, Zn 46.7% and Ag 10.1 oz./ton, containing 0.7% of the Pb, 27.7% of the Zn, and 1.2% of the Ag. The tailing contains only Pb 0.5%, Zn 0.3% and Ag 0.4 oz./ton. 1.2%, 5.6%, and 1.7% of the respective metals. The jig tailings, Pb 0.9%, Zn 0.1% and Ag 0.6 oz./ton, were floated to give a concentrate of Pb 46.0%, Zn 4.0% and Ag 31.4 oz./ton. 6.0% of the Pb, 4.0% of the Zn and 7.2% of the Ag. The tailing assays Pb 0.1%, Zn trace, and Ag 0.06 oz./ton, containing 0.6% of the Pb, 1.8% of the Zn and 0.8% of the Ag. AHE (33)

Milling Methods and Costs at the Concentrator of the Miami Copper Co., Miami, Ariz. H. D. Hunt. *United States Bureau of Mines, Information Circular* No. 6573, Apr. 1932, 25 pages.

The Miami ore is of chalcocite and pyrite with subordinate amounts of oxidized Cu minerals disseminated mainly in a quartz-sericite schist. The chalcocite is secondary and occurs chiefly as films on the pyrite. The oxidized Cu minerals are silicate (predominately), carbonates and oxides. Sulphides are removed from a mill feed assaying (average for 1930) Cu 0.716%, oxide Cu 0.112%, sulphide Cu 0.604% by bulk flotation by over oiling and adding flotation reagents in stages. The resulting coarse concentrate is reground and reconcentrated. The low-grade Cu concentrate from the cleaner cell of the primary circuit is reground and selectively floated to give a concentrate, assaying about Cu 40%, Fe 20% and insoluble 3%. The consumption of flotation reagents was (1930) pine oil 0.1619 lb., K xanthate 0.1481 lb., Na xanthate (experimental) 0.0024 lb., Na_2S (experimental) 0.0059 lb., reagent No. 323 (experimental) 0.0005 lb., lime 2.3426 lbs./ton of ore treated. Total costs were $0.29671/ton of ore. AHE (33c)

Milling Methods at the Balmat Mine of the St. Joseph Lead Co., Balmat, St. Lawrence County, New York. John B. Knaebel. *United States Bureau of Mines, Information Circular* No. 6574, Apr. 1932, 28 pages.

A sphalerite-pyrite-galena ore assaying Zn 12.29%, Pb 1.66% and Fe 12.93% was concentrated during 1930 by differential flotation to give 3 concentrates averaging as follows: Zn 55.88%, Pb 53.05%, and Fe 43.80%, respectively, with recovery of Zn 81.42%, Pb 59.01%, and Fe 45.08% (recoveries for first ½ of 1931 were 82.3%, 64.2%, and 66.2%, respectively). Tailings assayed Zn 1.90%, Pb 0.58%, and Fe 8.95%. Reagents in the Pb circuit are thiocarbanalid 0.1073 lb., cresylic acid 0.0307 lb., K xanthate 0.0239 lb., and NaCN 0.0954 lb.; in the Zn circuit $CuSO_4$ 2.2964 lbs., Na aerofloat 0.1280 lb., pine oil 0.1840 lb., lime 0.1840 lb., K xanthate 0.0208 lb.; in the pyrite circuit Barrett No. 4 0.0358 lb., K xanthate 0.1090 lb., $CuSO_4$ 0.1312 lb., Na_2S 0.1669 lb./ton of ore. AHE (33c)

The Flotation of Copper and Iron Pyrites in the Ore of the Aldermac Mine, Rouyn Area, Quebec. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 4-12.

A sulphide ore assaying Cu 1.98%, Zn 0.49%, Fe 40.5%, Au 0.09 oz. and Ag 1.18 oz./ton was floated to give a Cu concentrate, a Zn concentrate, a pyrite concentrate, and a pyrrhotite tailing. The use of soda ash-cyanide, lime-cyanide, or lime for conditioning agents gave Cu recoveries of 89.7%, 73.0% and 86.2%, respectively, in a product assaying Cu 14.75%, 18.91%, and 23.28%, respectively. For the most satisfactory test the following reagents were used: ball mill—lime 6.0 lbs.; Cu circuit—K xanthate 0.06 lb., pine oil 0.04 lb.; Zn circuit — K xanthate 0.05 lb., $CuSO_4$ 1.0 lb., pine oil 0.04 lb.; Fe circuit — amyl xanthate 0.30 lb., H_2SO_4 5.0 lbs., pine oil 0.06 lb./ton. Acidifying the pulp after Zn flotation yields the highest recoveries of pyrite (50-60%) in a product containing 48-50% S and 0.10-0.05% Zn. Dewatering the tailing from the Zn flotation prior to acidifying saves acid and does not affect pyrite recovery. AHE (33c)

Experimental Flotation Tests on Cobalt Ore from the Yorkshire Cobalt Mines, Ltd., Cobalt, Ont. J. S. Godard. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 160-163.

Cobaltite occurs in fine crystals in a diabase gangue assaying (2 lots) Co 2.19%, 2.70%; Ni 0.04%, 0.03%; As 2.85%, 3.55% and Ag 1.18 oz., 0.46 oz./ton. Flotation gave Co recoveries of 78% and 83%. The ore is slow to respond to flotation. Tabling of the tailings gives a low-grade product. AHE (33c)

Depression by Cyanide in Flotation Circuits. T. B. Brighton, G. Burgener & John Gross. *Engineering & Mining Journal*, Vol. 133, May 1932, pages 256-260.

The depressing effect of cyanide on sphalerite is less than on pyrite under the same conditions. The amount of cyanide required for complete depression of these minerals is inversely proportional to that abstracted by them. A study of the solubility of metallic xanthates indicates the formation of metallic xanthates on the mineral surface. Reagents reacting chemically with galena, such as dichromates, may also act as depressants. The xanthate coating may be due to the formation of a precipitate, a weak salt, or a complex ion. Some other effects of cyanides probably contributing to the depressing action on certain sulphides are: (1) with $ZnSO_4$, $Zn(CN)_2$ may be adsorbed, (2) complex cyanides and CN ions tend to change the polarity of the charge adsorbed on the sulphide surface, and (3) hydrolysis. CN affects the alkalinity of the pulp. WHB (33c)

Milling Methods and Costs at the Morning Concentrator of the Federal Mining and Smelting Co., Mullan, Idaho. M. P. Dalton. *United States Bureau of Mines, Information Circular* No. 6587, Apr. 1932, 11 pages.

The Morning mine ore consisting of an intimate mixture of Pb and Zn sulphides containing Ag, associated chiefly with siderite and quartz and assaying (typical) Pb 9.2%, Zn 6.70%, Fe 15.9%, Mn 1.9%, S 4.7%, CaO 1.2%, insoluble 39.3%, H_2O 3.5% and Ag 3.7 oz./ton is floated in 2 circuits to give a Pb and a Zn concentrate. Reagent consumption in the Pb circuit is $ZnSO_4$ 0.20 lb., Minerec A 0.11 lb., Barrett No. 4 0.05 lb., and Na_2CO_3 0.21 lb./ton of ore (cost $0.071) to give a concentrate of Pb 74.2%, Zn 5.8% and Ag 24.9 oz./ton for recoveries of Pb 91.0%, Zn 9.7% and Ag 81.1%. The Zn tailings assaying Pb 0.95%, Zn 6.50% and Ag 0.74 oz./ton are fed to the Zn circuit, treated with $CuSO_4$ 0.51 lb., Na xanthate 0.19 lb. and Barrett No. 4 oil 0.18 lb./ton of ore (cost $0.067), and yield a concentrate assaying Pb 2.8%, Zn 56.2% and Ag 4.8 oz./ton for recoveries of Pb 3.1%, Zn 85.7% and Ag 14.2%. Zn circuit tailings assay Pb 0.67%, Zn 0.38% and Ag 0.20 oz./ton. Pine oil (0.13 lb.) is added to the Pb concentrate to give a drier filter cake; lime (0.43 lb.) is used to assist in settling concentrates. Total costs for 1930 were $1.029/ton of ore milled. AHE (33c)

Principles of Flotation—An Experimental Study of the Effect of Xanthates on Contact Angles at Mineral Surfaces. IAN WILLIAM WARK & ALWYN BIRCHMORE COX. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 461, Feb. 1932, 48 pages.

Bibliography of 30 references. Refinements in the captive bubble method of Taggart, Taylor and Ince for measurements of contact angle between gas, liquid and mineral indicate errors in the pioneer work. Air does not displace water from the surfaces of many minerals, sulphides included, unless they be modified by some reagent. If a surface has been exposed to air before treatment with water, displacement of air by water may be slow. In a dilute solution of any xanthate (in some cases activating agents are necessary) contact of air with sulphide minerals is obtained. Gangue minerals, even in the presence of activators, do not respond to xanthates. Whenever contact is obtained, the angle is a constant for any particular xanthate, irrespective of the composition of the mineral; it increases with an increasing number of C atoms in the non-polar group of the xanthate. Evidence is presented that the adsorbed xanthate film is orientated with the ethyl group outward, being packed as closely as possible. The contact angle, therefore, is independent of the anchoring (polar) group. The effect of pH and cyanide on contact angle was investigated. JLG (33c)

Milling Methods and Costs at the Arthur and Magma Concentrators of the Utah Copper Co. H. S. MARTIN. *United States Bureau of Mines Information Circular* No. 6479, July 1931, 25 pages.

A monthly composite of mill heads contains (on basis of original ore) pyrite 2.60, chalcopyrite 1.71, chalcocite 0.21, covellite 0.17, bornite 0.11, total sulphide Cu 0.932, total non-sulphide Cu 0.052%. Average flotation reagent consumptions are, per ton of ore milled: CaO 3.79 (to give pH of 8.8-9.2), Na aerofloat 0.017, raw cresylic acid 0.18, and Aero brand cyanide 0.05 lb. Concentrates for April, 1930, assayed Cu 31.488, Fe 26.01, insoluble 5.29, S 35.20%, Au 0.242 and Ag 2.56 oz./ton. Recoveries were Cu 89.37, sulphide Cu 92.14, Au 72.98 and Ag 78.54%. Costs, which are detailed, total 30.217 cents/ton milled. AHE (33c)

Milling Methods and Costs at the Montana Mine Concentrator of the Eagle-Picher Lead Co., Ruby, Arizona. D. E. ANDRUS. *United States Bureau of Mines Information Circular* No. 6497, Sept. 1931, 14 pages.

Ore analyzing Pb 5.13, Zn 5.98, Cu 0.390%, Au 0.071 and Ag 8.17 oz./ton and consisting of galena, sphalerite and pyrite with subordinate amounts of chalcopyrite and tetrahedrite is concentrated by flotation. A Pb concentrate analyzing Pb 57.05, Zn 10.06, Cu 3.094%, Au 0.674 and Ag 74.02 oz./ton gives recoveries of Pb 92.59, Zn 14.02, Cu 65.33, Au 78.31 and Ag 75.49%. A Zn concentrate analyzing Zn 52.36, Pb 2.79, Cu 0.720%, Au 0.07 and Ag 12.40 oz./ton gives recoveries of Zn 68.29, Pb 4.23, Cu 14.41, Au 7.89 and Ag 11.92%. Tailings analyze Pb 0.19, Zn 1.26, Cu 0.095%, Au 0.011 and Ag 1.22 oz./ton, representing losses of Pb 3.16, Zn 17.68, Cu 20.24, Au 13.78 and Ag 12.58%. Reagents used, per ton of ore treated, are: CaO 0.995, Na_2CO_3 0.735, ethyl xanthate 0.057, thiocarbanalide 0.028, aerofloat 0.031, cresylic acid 0.150, pine oil 0.042, NaCN 0.219, $ZnSO_4$ 0.0640, Na_2SO_4 0.028, $CuSO_4$ 0.641 and Na silicate 0.258 lb. Costs from Oct. 1, 1929, to Apr. 1, 1930 were, in cents/ton: crushing and screening 32.12, grinding and classifying 25.20, flotation 59.81, filters 5.03, tailings disposal 6.23, water supply 7.55, miscellaneous 84.26 and total \$2.2020. AHE (33c)

Physical Chemistry of the Flotation Process. III. The Influence of Flotation Reagents on the Selective Wetting as the Physico-Chemical Characteristic of Their Collecting Power. M. E. LIPITZ & M. M. RIMSKAYA. *Tzvetnuie Metallui*, Aug. 1931, pages 990-1003.

The collecting ability of flotation reagents was determined by measuring the effect of their aqueous solutions of different concentrations on the wetting of paraffin (wetting isotherms). Measurements of the flotation activity of homologous series of alcohols, fatty acids, amines, phenols and xantates showed that the flotation activity increases with the lengthening of the hydrocarbon part of the molecules (with increasing assymmetry) parallel with the surface activity (i.e. in accordance with the rule of Traube), and with the decrease in solubility of the reagent in water. Only undissociated molecules actively influence the wetting of paraffin. Measurements of the flotation activity showed that xantates are analogous to other series of surface active substances. Measurements were made also of the flotation activity of soaps and oxidized paraffins. BND (33c)

Milling Methods and Costs of the Minas de Matahambre, S. A., Concentrator. A. R. KIRCHNER, J. V. GALLOWAY & W. P. SCHRODER. *United States Bureau of Mines Information Circular* No. 6544, 1931, 11 pages.

The ore consists of primary chalcopyrite associated with pyrite. Heads (1930) averaged 13% chalcopyrite, 7% pyrite, and 4.55% Cu; concentrates (flotation) 29.20% Cu and recovery 95.96%. Reagent consumption is potassium ethyl xanthate 0.409 lb., pine oil 0.272 lb., NaCN 0.031 lb., and lime (90-94% CaO) 0.206 lb./ton. Costs for 1930 were crushing and sorting 13.0 cents, concentrating 61.7 cents and total 74.7 cents per ton. AHE (33c)

The Concentration of a Lead-Zinc-Silver Ore from the Regal Silver Mines, Ltd., Albert Canyon, British Columbia. A. K. ANDERSON. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 112-115.

Five samples of sulphides of Pb, Zn and Fe in siliceous gangue assaying Pb 4.02-11.67%, Zn 1.20-3.17% and Ag 3.88-10.70 oz./ton gave recoveries of over 90% of the Ag and Pb by flotation using soda ash, cyanide and $ZnSO_4$ in the ball mills. Aerofloat No. 25 or K xanthate in the Pb cells and Aerofloat No. 25 + $CuSO_4$ or K xanthate + pine oil in the Zn cells. AHE (33c)

Flotation: Some Operating Details. KENELM E. ARMYTAGE. *Bulletin Institution of Mining & Metallurgy*, No. 329, Feb. 1932, 14 pages; discussion, No. 330, Mar. 1932, pages 15-24; No. 331, Apr. 1932, pages 27-28.

Methods of making an elutriation test of floatation pulp, the layout of a laboratory mill and classifier, an accurate dropper for laboratory flotation tests, a continuous feeder for testing plants, a laboratory cleaner cell, use of pH and a vacuum filter for preparing flotation solutions for pH determinations are described. AHE (33c)

Milling Methods and Costs at the Page Concentrator of the Federal Mining and Smelting Co., Kellogg, Idaho. G. S. PRICE. *United States Bureau of Mines, Information Circular* 6590, Apr. 1932, 6 pages.

Ore, consisting of an intimate mixture of Pb and Zn sulphides in a quartzite gangue, is concentrated by flotation. For the first 6 mos. of 1931, from a feed assaying Ag 4.32 oz./ton, Pb 10.95% and Zn 2.79%, a Pb concentrate assaying Ag 27.2 oz./ton, Pb 70.8% and Zn 6.9% with recoveries of Ag 88.9%, Pb 91.5% and Zn 35.1%, and a Zn concentrate assaying Ag 5.3 oz./ton, Pb 3.9% and Zn 51.3% with recoveries of Ag 3.7%, Pb 1.0% and Zn 55.0% were obtained at a cost of \$0.862 per ton of ore. Detailed costs for 1930 are given. Flotation reagents are Pb circuit: $ZnSO_4$ 0.88 lb., aerofloat (25%) 0.18 lb., and cresylic acid 0.07 lb.; Zn circuit: $CuSO_4$ 0.61 lb., Na xanthate 0.04 lb., Barrett No. 4 oil 0.06 lb., and pine oil 0.03 lb./ton of mill feed. AHE (33c)

Flotation Tests on Ore Sample from Sherritt-Gordon Mines, Ltd., Sherridon, Manitoba. G. B. WALKER. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 18-24.

An ore assaying Cu 2.53% (chalcopyrite), Zn 4.98% (sphalerite), Fe 38.65%, insoluble 21.50%, Au 0.01 oz. and Ag 0.51 oz./ton gave Cu recoveries by flotation of 90-94% in a 12-15% rougher concentrate depending on the reagent used. The flotation of the sphalerite in a high-grade concentrate presents considerable difficulty due to the fast floating pyrrhotite. AHE (33c)

Recent Improvements in Metallurgical Practice in Western Australia. B. H. MOORE. *Chemical Engineering & Mining Review*, Vol. 24, May 5, 1932, pages 263-266.

The main requisites for flotation are grinding to the proper fineness, formation of bubble or froth and selective action of the bubble on sulphide mineral. Flotation of Wiluna and Kalgoorlie ores has been entirely successful. The all-flotation plant of the Wiluna Co. started operation in 1931, and Lake View and Star Ltd. have introduced flotation with satisfactory extraction and cost of treatment. Concentrates from these ores can be roasted successfully without the use of extraneous fuel, except for the initial heating. Roasting must be conducted at a low temperature until the first S of pyrite is oxidized, after which the temperature is raised without harmful effect. Cyanidation of the roasted concentrates presents no difficulties. Bromocyanidation will soon be employed at the new plant of the Boulder Perseverance Co. This purely chemical process requires wet grinding to 200-mesh, agitation for 2 hours with cyanide solution, addition of 1 lb. of cyanogen bromide/ton, further agitation for 1 hour, addition of sufficient CaO to insure precipitation and filtration. The cyanogen bromide should be added with the alkalinity not over 0.002% CaO. WHB (33c)

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912

of METALS & ALLOYS, published monthly at Pittsburgh, Pa., for October, 1932. State of Pennsylvania, County of Allegheny, ss.

Before me, a notary public in and for the State and county aforesaid, personally appeared Richard Rimbach, who, having been duly sworn according to law, deposes and says that he is the editor of the METALS & ALLOYS and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 411, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, Chemical Catalog Company, Inc., New York; Editor, Richard Rimbach, Pittsburgh; Managing Editor, Richard Rimbach, Pittsburgh; Business Manager, Philip H. Hubbard, New York.

2. That the owner is: (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding one per cent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a firm, company, or other unincorporated concern, its name and address, as well as those of each individual member, must be given.) The Chemical Catalog Company, Inc., New York; R. W. Reinhold, New York; L. N. Thompson, New York; F. M. Turner, New York.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.) None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stocks, bonds, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date shown above is (This information is required from daily publications only.)

RICHARD RIMBACH, Editor.

Sworn to and subscribed before me this 23d day of September, 1932. [Seal] E. T. CHANCE, Notary Public.
(My commission expires March 7, 1933)

MANUFACTURERS' LITERATURE REVIEWS

500 **Blowers**—Bulletin 21-B14 of the Roots-Connersville-Wilbraham Co., Connersville, Ind., is devoted to their R-C-W blowers for pressure or suction service in connection with gas burners, crucible furnaces, annealing furnaces, annealing furnaces, smelting furnaces, drying ovens, etc. Other bulletins available are 22-B-10 for blowers used in ceramics, chemical processes, foundry cupolas, etc., and 23-B-10 for heavy duty blowers.

501 **Repairing for Profit**—A pamphlet with this title has been issued by the Linde Air Products Co., New York, N. Y. It contains two articles, one entitled "Oxy-Acetylene Welding in Automotive Repair" and the other, "Selling Auto Repairs Does Pay."

502 **Operating Recorder**—The Amthor Testing Instrument Co., Inc., 309 Johnson St., Brooklyn, N. Y., have prepared a leaflet describing their operation recorder which automatically records the entire operation of the machine on which it is installed.

503 **Lead Pipe**—A 23-page booklet prepared by the Lead Industries Association, 420 Lexington Ave., New York, N. Y., contains the new standards for lead pipe sizes and weights.

504 **Engineering Achievements, 1931**—The Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has reprinted from the *Electric Journal*, a group of articles which portray the accomplishments of engineering during 1931.

505 **Nickel Cast Iron Chart**—The International Nickel Company, 67 Wall St., New York, N. Y., has prepared a most convenient chart to assist engineers and foundrymen in the selection of suitable alloy compositions to meet special service requirements.

506 **Wire List**—The American Steel & Wire Co., 208 S. LaSalle St., Chicago, Ill., has issued a pocket-size booklet listing the products they make, from wire nails to elevator cables.

507 **Tool Steel Handbook**—The Columbia Tool Steel Co., Chicago Heights, Ill., has just sent out the fifth edition of their Tool Steel Handbook. It is a complete treatise on the use and handling of Columbia tool steels, together with new data and information supplementing previous editions.

508 **Plating Rolled Zinc and Zinc Die Castings**—A recent research bulletin published by the New Jersey Zinc Co., 160 Front St., New York, N. Y., has for its purpose the assembling, in as complete and concise a form as possible, the information necessary for the practical plating of rolled zinc and die cast zinc parts. The same company has prepared a wall chart giving the plating procedure step by step.

509 **Conveyor Belts**—The Wickwire Spencer Steel Co., 41 East 42nd St., New York, N. Y., has compiled a handbook devoted to metal conveyor belts. Each type is described and illustrated.

510 **Insulating Brick**—The Armstrong Cork & Insulation Co., Lancaster, Pa., has issued a 10-page booklet discussing their high temperature insulation for equipment in soaking pits, blast stoves, mill furnaces, etc.

511 **Case Hardening**—A 12-page leaflet sent out by the American Cyanamid & Chemical Corp., 535 Fifth Ave., New York, N. Y., describes the Aerocase process for case hardening steel in a liquid bath and gives applications of the process. Graphs illustrating the case structure are given.

512 **Electric Furnaces**—A leaflet prepared by the Falls Electric Furnace Corp., Buffalo, N. Y., shows examples of standard types of Falls electric furnaces of box and pot types.

513 **Heat Treatment**—The research staff of E. F. Houghton & Co., Philadelphia, Pa., has prepared a booklet entitled "Liquid Baths for the Heat Treatment of Steel." It presents the results of the study which the staff has devoted to this subject.

514 **X-Ray and the Airplane**—A leaflet sent out by the Kelley-Koett Mfg. Co., Covington, Ky., suggests a few of the many uses of X-ray equipment in the aircraft and allied industries.

515 **Alloy Metal**—The Jewell Steel & Malleable Co., Buffalo, N. Y., has sent out a leaflet showing the comparative physical properties of common castings and comparative machining tests of Jewell Alloy and other metals. Jewell Alloy is a heat-treated, white fracture, ductile iron of high yield and ultimate strength with an elongation of over 6%. It is said to be adaptable for all parts subjected to extreme heat, abrasion or corrosion.

ALPHABETICAL INDEX TO ADVERTISERS

◆ ◆ ◆

516 **Staybolt Steel**—The Bethlehem Steel Co., Bethlehem, Pa., has issued a leaflet devoted to their Mayari nickel-chromium steels for railroad staybolts.

517 **Gas Furnaces**—A booklet issued by the American Gas Furnace Co., Elizabeth, N. J., describes their gas carburizing machines, gas heating machines for continuous heat treating and their gas oven furnaces. A leaflet published by the same company illustrates their equipment for steel treating on a production basis.

518 **Steel**—According to a circular sent out by the Union Drawn Steel Co., Massillon, Ohio, they are prepared to furnish cold drawn and turned and polished steel, turned and ground shafting, free cutting screw steel, rounds, squares, flats, hexagons and special shapes. A leaflet prepared by the same company describes their Field Metallurgical Service.

519 **Steel**—A booklet prepared by the Jones & Laughlin Steel Corp., Pittsburgh, Pa., contains a detailed description and illustration of each group of products shown by the company at the 14th National Metal Exposition.

520 **Die Castings**—The Aurora Metal Co., Aurora, Ill., has sent out their Bulletin No. 3 describing their aluminum bronze die castings, giving their composition and characteristics.

521 **Arc Welding Supplies**—Section No. 3304 published by the Lincoln Electric Co., Cleveland, Ohio, describes their line of welding supplies and gives prices for them.

522 **Soldering System**—A leaflet recently issued by the Selas Company, Philadelphia, Pa., describes the new design and construction of their soldering irons. A chart shows their application to different plant requirements. The same company has prepared leaflets devoted to their sieve-cap burners, Bunsen burners and spear-flame burner tips.

523 **Ultramicroscope**—A recent folder of the Bausch & Lomb Optical Co., Rochester, N. Y., illustrates their slit ultramicroscope, a new instrument to simplify the study of colloids.

524 **Bronze Welding Rod**—The Linde Air Products Co., New York, N. Y., has just sent out a 20-page booklet describing the physical and welding characteristics of their Oxweld No. 25 M. bronze welding rod. It includes recommendations on a new technique for bronze-welding and for the fusion welding of brasses and bronzes.

525 **Ferro Carbon-Titanium in Steel Making**—A most attractive 110-page book published by the Titanium Alloy Manufacturing Co., Niagara Falls, N. Y., is a complete discussion of the use of ferro carbon-titanium in steel for forgings, rail steel, steel for castings, etc. The book is well illustrated.

526 **Welding Electrodes**—Bulletin GEA-1546A of the General Electric Co., Schenectady, N. Y., is devoted to their welding electrodes and accessories. Electrodes for cast-iron welding, for automatic welding and for building up hard surfaces are illustrated. Bulletin GEA-1593 of the same company describes their electric equipment for mine hoists.

527 **Darkfield Microscopy**—Bulletin No. 2 of E. Leitz, Inc., New York, N. Y., describes a novel illumination device and a new series of objectives which are said to contribute very materially to the enhancement of microscopical diagnosis of metal structures. Bulletin No. 3 of the same company discusses their simplified model MM-2 micro-metallograph.

528 **Grinding Wheels**—A leaflet sent out by the Manhattan Rubber Mfg. Division, Passaic, N. J., describes their rubber-bonded abrasive wheels and gives a list showing their range of application.

529 **Industrial Gas Equipment**—A folder prepared by Charles A. Hones, Inc., Baldwin, N. Y., shows illustrations and prices of their various types of burners, automatic blast gas soldering and bench furnaces, and soft metal furnaces.

530 **Metal Degreasing**—Bulletin 18 of the Dow Chemical Company, Midland, Mich., discusses their solvents for use in metal cleaning and degreasing work. A sketch of a very generalized degreasing system is shown.

531 **The Titusville Forge Company**—A short description of their history, plant facilities, products and organization has been prepared by the Titusville Forge Co., Titusville, Pa.

532 **Welder's Manual**—The American Steel & Wire Co., Chicago, Ill., has published a 32-page welder's manual which illustrates the right welding wire for each job. Methods for gas and electric welding are discussed.

533 **Testing and Balancing Machines and Instruments**—Bulletin No. 9 of the Tinius Olsen Testing Machine Co., Philadelphia, Pa., is devoted to their pendulum dial load indicator lever weighing system and recorder.

The Place of Research in Industry. F. B. JEWETT. *Proceedings American Petroleum Institute,* Section III, Dec. 1931, pages 27-33; *Bell Telephone Laboratories,* Mar. 1932, 14 pages.

The activities of the industrial research group are motivated by the same considerations and governed by the same rules as those which apply to other parts of the organization. The group itself differs from the other groups primarily only in the character of training of its members. They are skilled in a knowledge of the facts and methods of science rather than in the facts and methods of efficient factory operation, finance, purchasing, salesmanship, etc. Generally it is not the largest unit of the industry but in many it is organized both within and without as a most substantial bulwark, not only in the direction of continued progress but against the vicissitudes of hard times. The research laboratory has proved itself time and again to be the saving factor in what might otherwise have been a very unpleasant situation. Of all the types of work which are to be found in industry there is no group in which it is so difficult to recruit rapidly a trained and efficiently working personnel as in the group which comprises the industrial research organization. The period of preliminary training is long and arduous and can be undertaken only by men of ability who have an inclination toward the rigors of a scientific life. The period of acquainting even trained men with the intricacies of the applications of science to any particular industry is likewise long. Further the period necessary to mold wholly efficient men into an efficient team is long. These men not only have to be of proper caliber and thoroughly trained in their own field, but they likewise have to be properly organized and their group properly coördinated with the other parts of the business. If their inclinations lead them to delve somewhat in scientific research fields foreign to the one they are cultivating, no obstacles should be placed in their way provided they still continue to be of value as cultivators of their own field. Where material of patentable novelty develops as a result of industrial research work, the strongest possible patents must be sought for and obtained if the work is to bear full fruit and the industry is to be protected in the time, knowledge, labor and expenditure which it has given. Engineering Efforts of 1931 Directed Toward Economy in Operations. E. F. ROSS. *Steel,* Vol. 90, Jan. 4, 1932, pages 155, 159.

In spite of the continued depression, 1931 witnessed many new and remarkable accomplishments in the iron and steel industry. Blast furnace stacks were kept idle for short periods of time and restarted quickly without affecting pig iron quality. Mechanical control was introduced in open-hearth practice. Steel of the highest quality was produced at a lower cost. The forging industry developed a new method of pressure forging and the welding industry adopted codes governing fusion welding. Other developments include improvements in rolling mill equipment and control apparatus, improvements in heat treating methods, furnaces and refractories, improvements in machine tool design and in handling equipment, and the introduction of stainless steel rivets in fabrication. Proceedings of the American Society for Testing Materials. Part I. Committee Reports and Tentative Standards. Part II. Technical Papers. Vol. 34. American Society for Testing Materials, Philadelphia, 1931. Paper, 6 × 9 inches, 1119 pages, 1027 pages. Price $5.50 each.

About 330 pages of part 1 and 430 of part 2 refer to metallic materials. Besides the material included in these volumes, the Society has separate publications including 11 papers in a symposium on welding and 28 papers in a symposium on effect of temperature on properties of metals. The Society is active in research along metallurgical and metallurgical testing lines and its publications are always of extreme value to metallurgists. These volumes are no exception.

One of the highly important steps is the recommendation of the committee on mechanical testing that the term "yield strength" with a statement of the permanent set at that strength be used instead of "yield point." Thus the confusion caused by giving data for elastic limit, proportional limit, yield point, etc., in technical literature without adequate information as to the amount of plastic deformation taken as the criterion, may be avoided.

The metallurgical articles have been abstracted in *Metals & Alloys* from preprints on their appearance and have also been again listed to give the page reference in the final publication and include information brought out in discussion. H. W. Gillett (0) -B-

PROPERTIES OF METALS (1)

Mechanical Properties of Copper. (Proprietés mécaniques du cuivre.) Alexandre Krupkowski. *Revue de Métallurgie,* Vol. 28, Oct. 1931, pages 529-545; Nov. 1931, pages 598-609; Dec. 1931, pages 641-660; Vol. 29, Jan. 1932, pages 16-33; Feb. 1932, pages 74-92.

Formulas given by C. Bach and C. A. Bartella for elongation of usual tensile specimens per unit of length are only approximate. On the basis of theoretical consideration new formulas for Cu are proposed which, after experimental determination of the constants for annealed Cu become:

$$\text{Elongation } A = 0.409 + \frac{2.59}{3.1\,m + 1}$$

Distance between the punch marks expressed in original diameter of the test bar

$$m' = m\,(1.408 + \frac{2.59}{3.1\,m + 1})$$

$$\text{Reduction of area } \frac{d}{d_o} = \sqrt{\frac{1}{1 + \left[0.409 + \frac{2.59}{(3.1\,m + 1)^2}\right]}}$$

These formulas checked well with the results of tests made on annealed copper. A slight tendency towards giving lower values for diameters was observed. The amount of elongation for any given load lower than the one necessary for production of striction can be expressed by the formula $A_s = A + \frac{1}{2}(A\text{-}3a - 2)z$ where A is the total elongation obtainable on the material, z the percentage of deformation, a is the elongation before the beginning of striction.

Tensile strength is given as $R_z = R/(1 - z)$

Reduction of area is expressed as $\Theta_z = 1 - (1 - \Theta)/(1 - z)$

The work consumed in production of any elongation before the striction begins is

$$L_a = \frac{R.a.l_o.S_o}{10^3}\,(0.75 + 0.25\,\frac{E}{R})\ \text{kg./m.}$$

where a is elongation before the beginning of the striction, R. tensile strength in kg./mm.^{2}, l_o initial length, S_o initial cross-section in mm.^{2}, E elastic limit in kg./mm.^{2} Total work required for breaking a specimen can be expressed:

$$L_A = \frac{R \cdot A \cdot l_o \cdot S_o}{10^3}\,(\,1\text{-}0.25\,\frac{a}{A} + 0.25\,\frac{E}{R}.\frac{a}{A})\ \text{kg./m.}$$

where A is elongation after rupture. Figures calculated from these formulas agree with the results of tensile testing of drawn Cu wire. The possibility of latent heat of deformation was checked by proper measurement of the temperature of bars under test but it was found that almost all work required for fracturing is transformed into heat, proportionally raising the temperature of the bars. After a comprehensive survey of work already done on physical properties of Cu a set of experiments for the determination of physical properties of Cu at elevated temperatures is described. Provisions for testing in different atmospheres were made. Recrystallization of drawn commercial electrolytic Cu begins at 320° and is completed at 340°C. Testing annealed Cu in nitrogen showed that there is a hardening range for Cu between 150° and 500°C. as was reported by previous investigators. Within it tensile strength reaches its maximum; yield point remains practically constant; elongation drops slightly near the recrystallization point but recovers again and begins to decrease steadily only after 650°C. Starting with 567°C. all specimens were reduced to a point in breaking. In the malleable range from 500° to 800° C. the strains are relieved instantaneously. At 850° the cohesion between the grains is much reduced and the specimens break under a light load without any deformation. Testing in air and CO_2 showed that the physical properties were the same as when tested in neutral gases. Electrolytic Cu not remelted but annealed in CO_2 and pulled in CO_2 had elongation and reduction of area decreased to about 50% of the normal due to the lack of homogeneity of metal. Freed from hydrogen by heating for 10 hours in vacuum at 600° C. cathode Cu tested in hydrogen at room temperature did not exhibit any changes, but at high temperatures lost its ductility. Liquid air temperatures do not reduce the ductility of Cu. Brinell and Meyer formulas for hardness as applied to copper were checked. Meyer's relation $P = a.d^n$ is exact and his hardness represents the true hardness of the underlying metal while Brinell's does not. The detailed mathematical analysis and experimental study with cones of different angles showed that the difference between hardness numbers obtained with a cone and with balls depends on the difference in the processes of cold deformation depending on the shape of indenting tool and the charge. Meyer's formula shows therefore that for the metals which harden by straining under a charge the charge grows faster than the lateral surface, implying the relation between the charge and the amount of strain of the underlying metal. There is no need for introducing a coefficient of friction to explain the difference between cone and ball readings. The curve of hardness expressed as load per unit of lateral area varies as a function of the angle of the cone, passing through a maximum. Hardness expressed as load per unit of area of circular section increases with the diminution of the angle of the cone. The relation between the hardness figures obtained with a cone and with a ball is not constant depending both on the exponent (n) and the hardness of the metal. Taking readings of the impressions made on identical spots with the same instruments and after repeated annealing in neutral atmosphere the hardness of annealed Cu was found to be 13.5 Meyer units being independent of the shape of indenting tool and the load. Applying geometrical considerations a formula was derived for the rim formed around the impression obtained in hardness testing. It was checked experimentally on Cu having different degrees of strain. For dead soft Cu the edges are drawn down forming a funnel shaped impression. With about 4% strain the edge of impression exactly corresponds to the surface plane of the specimen. With higher strain a ridge above the surface of the specimen is formed. The coefficient of the rise of this ridge becomes constant above 17% strain. The shape of the ring formed by this ridge can be calculated by the formulas given, both for ball and cone impressions. The spread of the ring of deformation is a function of the elastic limit and the hardness corresponding to the average pressure. After critically reviewing previous work hardness determinations on strained cylinders and drawn wires were made. The hardness of Cu increases rapidly up to 30% of straining, and more slowly thereafter. Strained approximately 55%, hardness expressed as average load is given by a number independent of the shape of the tool and the load. The experimental procedure of the previous workers for determination of hardness of Cu at elevated temperatures is described pointing out the probable sources of error. Hardness at high and low temperatures was determined by impressions made with a stellite cone either immersed together with the specimen in properly controlled cooling bath or inserted in an electric furnace in a CO_2 atmosphere. Two series of annealed Cu and one of strained were tested. The curves of hardness change their slope at the temperature of recrystallization. Hardness of cold worked Cu drops rapidly until the recrystallization temperature remains constant for a while and then merges with the curve for annealed Cu. The latter is formed of 2 branches convex towards the axis of the temperature and uniting at the point of the recrystallization. The relation between Brinell hardness and tensile strength is very close for Cu. After a comprehensive review of opinions and experiments already done on the impact value of Cu a proper set up was devised. Notched bar specimens were broken on a Charpy machine. An accurate thermocouple was soldered inside of the notch. The supporting anvil was water cooled while the specimen was brought up to the desired temperature by means of a blow torch. The actual temperature at the moment of breaking was read directly. For low temperature testing the same arrangement was used only the specimens and the thermocouple were placed either into liquid air or a mixture of acetone with dry ice. For strained Cu the impact value decreases continuously to 500° C. with only a slight increase at the recrystallization temperature. Above 500° C. it increases rapidly reaching at 700° C. the value for annealed Cu. For Cu annealed in an inert gas (nitrogen) the maximum impact value is around the temperature of recrystallization (340° C.) after which it decreases. When the Cu is annealed in hydrogen its impact value remains practically constant between 50 and 500° C. 52 tables, 110 diagrams and microphotographs, 135 references. JDG (1)

Determination of Some Physical Properties of Magnesium Crystals. (Bestimmung einiger physikalischer Eigenschaften von Magnesiumkristallen.) E. Goens & E. Schmid. *Naturwissenschaften,* Vol. 19, May 1, 1931, pages 376-377.

The elastic and torsional moduli of differently oriented crystals of pure Mg were determined dynamically and from the results obtained the following elastic parameters have been calculated (in 10^{-13} cm.^{2}/dyne): $S_{11} = 22.3$; $S_{33} = 19.8$; $S_{44} = 59.5$; $S_{12} = -7.7$; $S_{13} = -4.5$. Addition of up to 2.3% Zn scarcely affects the elastic modulus. The thermal coefficient of expansion varies very little with change of orientation. The limiting value of the electrical resistance of the crystal is about $3.77 \times 10^{-6}\ \Omega$ cm. parallel to the hexagonal axis and $4.54 \times 10^{-6}\ \Omega$ cm. perpendicular to this axis. The dependence of the above properties on the orientation is compared with that previously found in the case of Zn and Cd. The differences cannot be explained on the deviation of the lattice from that of the most densely packed hexagonal lattice. WHB (1)

Emission from Aluminum and Its Alloys. (Emission von Aluminium und seinen Legierungen.) R. Hase. *Zeitschrift für technische Physik,* Vol. 13, No. 3, 1932, pages 145-155.

The radiation properties of Al are investigated as a function of the quality of the surface, of temperature, of wave length and of the angle of emission. The comparison with a black body shows in the range of 1 to 10 μ and at 400° C. a very small emission, particularly for rough surfaces, while a thick oxide layer gives approximately half the radiation of that of the black body in the same wave-range. Wien's law of dislocation takes the form of λ max. $\times$ T = 2700. Further the law of Stephan was confirmed whereby the emission increases with the fifth power of the absolute temperature; the formula for polished Al is $Q = 0.58 \times \left(\frac{T}{100}\right)^5 \frac{\text{kg. cal.}}{\text{m.}^2\ \text{hr.}}$ for vertical radiation. A great number of numerical values is given for powder and alloys of Al. 8 references. Ha (1)

On the Elastic Anisotropy of Iron. (Über die elastische Anisotropie des Eisens.) E. Goens & E. Schmid. *Die Naturwissenschaften,* Vol. 19, June 5, 1931, pages 520-524.

Sufficiently large Fe-single crystals (Armco) were prepared by recrystallization after critical stretching and the moduli of elasticity were determined dynamically by transverse vibration and the torsion moduli by a static method. The data obtained, show the remarkable anistropy of Fe crystals: $E_{(100)} = 13{,}500$ kg./mm.^{2}, $E_{(111)} = 29{,}000$ kg./mm.^{2}, $G_{(100)} = 11{,}800$ kg./mm.^{2}, $G_{(111)} = 6.100$ kg./mm.^{2} Measurements and interpretations of the anisotropy of cold-rolled electrolytic Fe are set forth. A minimum of the elasticity modulus was noticed at a 40°-45° angle with the direction of rolling. A deviation of 35% from the maximum perpendicular to the same direction was established. EF (1)

The Increase of Heat Radiation of Aluminum by Surface Treatment. (Ueber die Erhöhung der Wärmestrahlung des Aluminiums durch Oberflächenbehandlung.) G. Eckert. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 4, Jan.-Feb. 1932, pages 31-32.

A few experiments are described which the author believes point to a remarkable possibility of an increase of the heat radiation from Al surfaces. An ordinary piece of Al pipe heated in the middle by a Bunsen flame of 1170° C. melted after 2¼ minutes but did not if the piece was coated with a very thin layer of sodium silicate. Ha (1)

PROPERTIES OF FERROUS ALLOYS (3)

Hollow Boring Tools. (Hohlbohrstähle.) R. Hohage. *Glückauf,* Vol. 67, May 23, 1931, pages 709-710.

The steel used for these tools must be of highest quality as they are subject to several vibration stresses. A few examples are shown where invisible defects on the outer and inner surface led to fracture. A refined electric-steel with 0.75% C which is used for these drills had a tensile strength of 73.6 kg./mm.², an elongation of 11.2%, a reduction of 40% and a notch toughness of 4.1 mkg./mm.². Ha (3)

Develops New Steel for Piercing Points and Plugs in Seamless Tube Making. *Steel,* Vol. 90, Jan. 18, 1932, page 25.

Crusco Steel is a new, superior alloy steel developed by the Crucible Steel Casting Co. for the manufacture of piercing points and rolling mill plugs. The alloying constituents are Cr, V, W, Co, and Ni. JN (3)

Steels for Rolling Mills and Grinding Mills. (Stähle für Walzwerke und Rollergänge.) *Tonindustriezeitung,* Vol. 56, Jan. 14, 1932, page 64.

With due consideration that steels for the above purposes must combine hardness and toughness, the following materials are considered as to their suitability: cast steel, Mn hard steel, chilled cast iron, common open hearth steel, Cr steel and Mn steel. The properties of these materials are dealt with. GN (3)

The Properties of Some Silico-Manganese Steels. G. Burns (Research Department, Woolwich). *Iron & Steel Institute, Advance Copy* No. 6, May 1932, 22 pages.

The results of an extensive study of the properties of steels containing as much as 2.6% Si and 2% Mn are reported. The C ranged from 0.36 to 0.54%. In normalized steels suitable for structural purposes, both Si and Mn raised the elastic limit, yield point, and tensile strength, and lowered the elongation and impact values. With more than 1% Mn, over 1% Si produces quite low impact values. It is doubtful if any of the high-Si steels show properties that can not be equalled or excelled by Mn steels with normal Si. In the hardened and tempered condition, both Si and Mn increase strength and lower ductility. Mn has the greater effect. The Si-Mn steels require a high quenching temperature. These steels are quite susceptible to mass effect, and it is sometimes desirable to quench in water. Steels that are to be quenched in water should not contain over 0.45% C. Mn is more effective than Si in decreasing the mass effect. Steels lying at the extreme limits of composition usually specified for heat-treated springs were investigated. The yield ratio increased with the Mn content. Fatigue tests indicated that a high-Si, low-Mn steel was less resistant to surface irregularities than other steels. On the other hand, the steels with a low Mn content are more readily decarburized. 18 references. JLG (3)

The Effect of Cold Working Prior to Heat Treatment on the Physical Properties of Steels. (Der Einfluss vor der Wärmebehandlung vorgenommen Kaltbearbeitung auf die Festigkeitseigenschaften von Stählen.) Erich Greulich. *Archiv für das Eisenhuttenwesen,* Vol. 5, Mar. 1932, pages 487-491.

Cold working prior to annealing generally accelerates the structure changes produced by annealing. Studies were made of 7 C-steels and austenitic Cr-Ni-steels for effect of cold rolling on changes in tensile strength and elastic limit. These properties are closely connected with transformation of banded pearlite into granular cementite and also with precitation hardening during heat treatment. Composition of the 7 steels studied is given in following table:

		Composition in %						
No.	Material	C	Si	Mn	P	S	Ni	Cr
1	St C 16.61	0.12	......	0.40	0.017	0.024	......	......
2	St C 25.61	0.29	0.06	0.40	0.020	0.013	......	......
3	St C 45.61	0.46	0.30	0.75	0.021	0.028	......	......
4	St C 60.61	0.61	0.34	0.83	0.022	0.016	......	......
5	Ni steel	0.18	0.26	0.49	0.020	0.021	5.14	0.03
6	Stainless steel	0.19	0.56	0.45	0.019	0.010	0.56	14.50
7	Stainless steel	0.37	......	2.02	0.028	0.033	35.20	10.50

With C steels containing more than 0.3% C crystal change of cementite and softening of steel by annealing below A_1 are rapidly accelerated by cold rolling. Ordinary C steels are strengthened from annealed condition greater by cold rolling and also are weakened quicker by annealing in range of decreased tensile strength, than steels with banded pearlite. With Cr-Ni steels, increase in tensile strength and elastic limit as affected by precipitation hardening was greater after slight amount of cold rolling and could be produced with shorter annealing time, as well as any higher range of temperature than with cast steels. With about 10% cold rolled reduction, amount of improvement in physical properties is decreased, and from 10% up to roughly 25% no further increase in tensile strength and elastic limit was obtained. With very uneven cold rolling, carbide segregation during subsequent annealing led to cracks. Effect of cold rolling, approximately 25% cold roll reduction, followed by annealing below A_1 on the physical properties of 6 steels is given in table below, each cold rolling was approximately 5% cold roll reduction:

		Number of Cold Rollings and Intermediate Anneals

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Note on the Interaction of Aluminum and Water Vapour. Richard Seligman & Percy Williams. *Institute of Metals, Advance Copy* No. 597, Mar. 1932, 4 pages.

Briefly reviews conflicting results reported on reaction of Al with steam. Subjected Al sheets of varying purity and an Al-Si alloy to steam at 300-350° C. No serious attack was observed, even when air was excluded from the system. Care was taken to prevent contact of the samples with liquid water. 5 references. JLG (4)

The Phenomenon of "Friction-Oxidation" with Electrolytic Copper. (Die Erscheinung der Reiboxydation an Elektrolytkupfer.) M. Fink & U. Hofmann. *Zeitschrift für Metallkunde,* Vol. 24, Mar. 1932, pages 49-54.

The friction set up between two Cu discs under a load of 40 kg., rotating at 250 r.p.m. with and without slip was measured as a function of time in an Amsler friction machine, in an atmosphere of air, nitrogen, and oxygen, and the abraded dust collected for chemical and X-ray crystallographic analysis. The powder formed in air increases in oxygen content as the test proceeds, is mostly Cu_2O but contains some CuO with Cu present also. Practical examples of the process of "friction-oxidation" are discussed. RFM (4)

Resistance of Copper and Its Alloys to Corrosion. (Le cuivre et ses alliages devant la corrosion.) A. Matagrin. *Industrie chimique,* Vol. 18, Mar. 1931, pages 160-163; May 1931, pages 317-318.

Describes the chemical properties of cuprous oxide, resistance of Cu to atmospheric corrosion, resistance of cuprous oxide to mineral acids and resistance of pure Cu to organic reagents. WHB (4)

The "Fogging" of Nickel. W. H. J. Vernon. *Institute of Metals, Advance Copy* No. 600, Mar. 1932, 14 pages.

Describes a study of the characteristic filming or "fogging" that occurs on polished Ni. By exposing similar samples in transparent and opaque jars it was observed that light increased the rate of fogging. In the early stages the film consists of Ni SO_4 with free H_2SO_4. In the later stages it consists of basic Ni SO_4. The conditions most favorable for forming the Ni film are not favorable for the tarnishing of Cu. The fogging of Ni is attributed to the catalytic oxidation of atmospheric SO_2 at the Ni surface. The formation of the film may be largely suppressed by preliminary exposure to dilute H_2S, which supposedly poisons the catalyst. Fogging may be prevented by alloying Cr with the Ni. It cannot be suppressed by producing an oxide coating by heating to low temperatures. 6 references. JLG (4)

Grain Size, Eutectic Alloys and Corrosion. (Korngrösse, Eutectikum und Korrosion.) M. Werner. *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, pages 85-87.

A discussion of the corrosion of Pb. Large grains increase corrosion. It is shown that impurities which form solid solutions increase the grain size greatly. Local galvanic elements may afford corrosion protection, if the addition forming the local element is more noble than Pb. This effect is lost if the addition forms appreciable quantities of eutectic with Pb, though if the addition is worked into Pb mechanically (rather than melted with Pb) the effect may again be present. RFM (4)

The Influence of Moisture on the Reaction Between Sulfur and Silver. John Wm. Smith. *Journal Chemical Society,* Apr. 1931, pages 860-863.

To determine if moisture is necessary for the reaction between S and Ag, experiments were performed in which powdered S in contact with Ag-strips was sealed in glass tubes with and without P_2O_5. In the tube containing moisture the Ag strip was appreciably tarnished within a day, and after a year had almost entirely disintegrated. In the tube containing P_2O_5, however, the strip remained completely unchanged for a year, increasing the temperature up to 150-160° C. having no effect. Drying with $CaCl_2$ instead of P_2O_5 also inhibits the reaction considerably. It is shown that the reaction is not dependent on the presence of O_2. Ha (4)

Some Causes of the Staining of Strip Brass in Process. Charles K. Skinner. *Metal Industry,* N. Y., Vol. 30, Apr. 1932, pages 140-142.

Brown, black and red stains result from the annealing operation or from the combination of annealing and pickling. Black stains appear readily on annealing in an oxidizing atmosphere. Red and brown stains from annealing are scarce. Red stains are caused by pickling stock in hot solutions or in solutions having high localized acid concentration if stock has black oxide of Cu on it. Another common cause is having 2 adjacent laps of coiled stock whose surface is covered with oxide, in contact while pickling. Impure wash water brings about staining. With proper annealing equipment to eliminate oxidation and with proper attention to the other factors, red stains can be practically prevented. PRK (4)

The Protection of Magnesium Alloys Against Corrosion. H. Sutton & L. F. Le Brocq. *Engineering,* Vol. 132, Dec. 18, 1931, pages 771-772.

Condensed from paper read before the Institute of Metals, Zürich, Sept. 14, 1931. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA6. LFM (4)

Corrosion of Steels at High Temperature. L. Losana. *Industria Chimica,* Vol. 6, Jan. 1931, pages 11-15; *Vancoram Review,* Vol. 2, Oct. 1931, pages 147-148.

24 samples of steel with different contents of Ni, Cr, W, V, Mo were exposed to the action of air as well as to exhaust gases at 600°-1050° C. Mo was found to retard corrosion greatly, with low as well as high Ni. W had little influence except in combination with Mo. V above 1% increased corrosion. The results are of the same order in air as those in exhaust gases. Ha (4)

Water Pipe Conduits with Protective Layers on the Inside. (Wasserleitungsröhren mit innen angebrachter Schutzschicht.) *Die Röhrenindustrie,* Vol. 24, July 2, 1931, page 159.

The various methods leading to the formation of an inside protection (a) while being in use and (b) to the artificial protective layer before the installation, are reviewed. The latter group refers mainly to a discussion on galvanized tubes and pipes with bituminous and concrete layers. The utilization of Pb and Cu pipes is considered. EF (4)

Corrosion in Spots Through Drops. (Lochartiger Anfrass durch Tropfen.) W. Werner. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

The author endeavored to prove experimentally Evans prediction on the electro-chemical mechanism of spot corrosion under a drop of water. This was made possible by electrically isolating from its surrounding part of the iron surface below the drop of water. The largest e.m.f. measured was somewhat above 100 mv. It is further shown that aired electrodes are nobler than electrodes which are not aired when whirls of water are absent. Evans theory fits the observations of the authors, but they contradict the theories which have been developed by Maass & Liebreich. GN (4)

Effect of Oxygen Concentration on Corrosion Rates of Steel and Composition of Corrosion Products Formed in Oxygenated Water. G. L. Cox & B. E. Roetheli. *Industrial & Engineering Chemistry,* Vol. 23, Sept. 1931, pages 1012-1016.

Bibliography of 20 references. With varying amounts of O in water, the corrosion rates of steel are shown to be proportional to the O concentrations approximately for concentrations below 5.5 cc. per liter. At higher values the relationship is not linear, and the deviations become more pronounced as the O concentrations increase, indicating that the resistance to the transfer of O to the metal surface increases because of changes in the nature of the corrosion products. MEH (4)

Corrosion Rates of Steel and Composition of Corrosion Products Formed in Oxygenated Water as Affected by Velocity. B. E. Roetheli & R. H. Brown. *Industrial & Engineering Chemistry,* Vol. 23, Sept. 1931, pages 1010-1012.

It has been found that, as the rotational velocities of steel in oxygenated water increased, the corrosion rate increased to a maximum, decreased to a very low value, and increased again to a somewhat higher value at very high velocities. The variations in corrosion rate are due to (1) differences in the type and uniformity of corrosion-product film formed, (2) changes in liquid-film thicknesses, (3) erosion. (4)

Corrosion and Its Technological Aspects. (Die Korrosion in ihre technologischen Zusammenhängen.) E. H. Schulz. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker,* Oct. 20, 1931, Berlin.

The process of corrosion of a metal under given conditions can safely be judged only when all factors that affect the process are known. Some examples are given which show that in many cases slight differences in the nature of the corroding medium have a much greater effect upon corrosion than have variations of composition of the material subjected to corrosion. It is incorrect to speak of corrosion resisting alloys; there are only materials which are resistant to one or several media of corrosion. The factors which influence corrosion are classified: (1) composition and treatment of the material, (2) construction and shape of the material, (3) the media of corrosion which, in turn, are subjected to a great variety of conditions, (4) additional conditions such as wear, vibrations, stray currents and others. The importance of many individual effects upon corrosion is still underestimated. GN (4)

The Fight Against Rust. (Im Kampf gegen den Rost.) H. Wehner. *Gesundheits-Ingenieur,* Vol. 54, Jan. 3, 1931, pages 1-6.

Free and combined CO_2 as factors which cause rust are discussed. WHB (4)

Intergranular Corrosion. *Chemical & Metallurgical Engineering,* Vol. 39, Mar. 1932, page 129.

Abstract of paper by P. Payson given before American Institute of Mining and Metallurgical Engineers, Feb. 1932. Intergranular corrosion of steel of the 18-8 class is discussed. See *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 238. (4)

The Results of Accelerated Corrosion Tests on Stainless Steels (Résultats d'essais activés de corrosion sur aciers inoxydables). Jean Cournot. *Comptes Rendus,* Vol. 193, Nov. 30, 1931, pages 1091-1093.

The author describes the results of a number of corrosion tests made on stainless steels conforming to specifications laid down by the Services Techniques de l'Aéronautics francaise. 7 of the 18-8 type, one containing 10% Cr and 23% Ni, 2 containing 3% Cr and, as a basis of comparison, a pure Fe. The test methods used were as follows: (a) alternate immersion over periods of 10, 20, and 50 days; (b) spray tests over periods of 10, 20, and 50 days; (c) perhydride tests over periods of 1, 2, and 3 days. Artificial sea-water, made to specification, was used. The loss in weight, the breaking stress and deflection in stamping (presumably Erichsen test, and the appearance of the pieces were carefully noted. Cournot concludes that the perhydride test is less sensitive than the others but has the advantage of being extremely rapid. The alternate immersion and emersion method gives the most regular results, particularly in so far as loss of weight measurements are concerned. The spray test shows up variations in mechanical properties due to the formation of pits in the samples. In the stamping test, determinations of breaking strengths are definitely more valuable than deflection determinations. It is concluded that the results obtained by the different methods referred to allow a very clear idea of the resistance of these steels to corrosion. The article is accompanied by a diagram showing the results of the loss in weight measurements obtained. OWE (4)

Special Austenitic Steels for Severe Corrosion Resistance. James A. Parsons, Jr. & Earl Ryder. (Duriron Co.) *Metals & Alloys,* Vol. 3, Mar. 1932, pages 56-60.

The authors discuss the requirements for metal parts in steel pickling equipment where the corrosive is acid with very substantial amounts of ferric and ferrous salts in solution. They describe their methods of test which have been arranged to give as near as possible the service corrosion conditions. Ni-Cr austenitic steels from 8-35% Ni and 2.5-18% Cr, sometimes with small percentages of Mo and Cu added, were tested. The effects of heat treatment and C content upon the intergranular attack are discussed. Suitable increase in Cr, lowering the C content, and the judicious use of added elements are the means of avoiding the intercrystalline attack. WLC (4)

Guarding Against Corrosion in Acetic Acid Equipment. D. F. Othmer. *Chemical & Metallurgical Engineering,* Vol. 39, Mar. 1932, pages 136-139.

Anhydrous acid dissolves or disintegrates fibrous materials such as wood and packing material. Use of wood is limited to strengths of acid up to 25%. Rubber hose is extensively used for handling cold vinegar. Wrought Fe and mild steels are not satisfactory materials. Cu has a satisfactory life in all concentrations and temperatures if liquid is free of dissolved oxygen: Cu vessels and tubing have been successfully Ag-plated to give almost perfect resistance to hot acid vapors mixed with air. Al bronze castings are satisfactory if free of pores. Duriron is unaffected by acid of all concentrations and temperatures even in the presence of oxygen, and it is used in contact with Cu. The latest improved technique of welding of stainless steels of low C content removes the danger of cracking when such joints are used in vinegar or stronger acid. Thin parts made of Ta which has almost perfect resistance to acetic acid, are electroplated with base metal to desired thickness and strength. Pure acid containing less than 4% water has no effect on Al: however if formic acid is present as an impurity, corrosion occurs. PRK (4)

Corrosion and Erosion. *The Steam Engineer,* Vol. 1, Apr. 1932, pages 295-297.

A review is given of the causes of corrosion under different conditions met with in steam plant operation. AHE (4)

Electrical Methods Proposed for Preventing Scale and Corrosion in Steam Boilers. Wm. L. DeBaufre. *Combustion,* Vol. 3, May 1932, pages 21-29.

Comprehensive discussion of 4 proposed electrical methods, (1) Nee-wat system; (2) Kirkaldy system; (3) Hauptvogel system; and (4) Agfil system. Theories and principles involved are explained. Operation of some of the principal methods is described. The writer concludes that there may be some merit in electrical methods of preventing scale and corrosion in steam boilers, but that such methods may not be a preventative in all cases. In any such application the complicated arrangement of tubes, drums, etc. in a modern steam boiler makes it practically impossible to obtain a uniform effect of the impressed electrical current throughout the whole structure. Considerable research will probably be required to make definite determinations, and also whether electrical methods have any advantages over chemical methods or both methods should be used. DTR (4)

New Developments of the Condenser-Tube Problem. Siegmund Hirsch & Alfred Schimmel. *Shipbuilder,* Vol. 38, Mar. 1931, pages 194-195.

In a review of the methods adopted to prevent condenser tube corrosion both in the manufacture of tubes and in their subsequent treatment, it is stated that the reports of the German Corrosion Committee show that it has been possible by these means to appreciably reduce the corrosion in condensers of reciprocating steam engines, but that much damage is still experienced in turbines. Reference is also made to the difficulties encountered in the manufacture of Ni-Cu condenser tubes and to the improvements which have been effected in recent practice. The 80% Cu, 20% Ni alloy is considered the most suitable. WHB (4)

Protective Coatings in Water-Tube Boilers and Steam Turbines. Clarence J. Hunter. *Steam-Plant Engineering,* Vol. 1, Feb. 1932, pages 37-38.

A general discussion. AHE (4)

Tube Failures in 1,400 lb. Boilers. *Power,* Vol. 74, Oct. 13, 1931, pages 542-543.

A report presented at the annual meeting of the German Association of Boiler Owners, 1931. The greatest difficulty encountered in operating the 100 atmosphere pressure boilers at Mannheim was corrosion of boiler tubes. The failures are described in detail with the various treatment methods used. There is no fundamental connection between corrosion and high pressure. Mo steel tubes were used, thus permitting thinner walls due to higher yield point. AHE (4)

Steel, Iron and Alloys. C. E. Plummer. *Factory & Industrial Management,* Vol. 8, Jan. 1931, pages 50-51.

A list of 186 American alloys is tabulated which are grouped as follows: 1. Light-metals, resistant against atmospheric corrosion; 2, Cr alloys, stainless steels, resistant against atmospheric corrosion and HNO_3; 3. Cr alloys, very resistant against atmospheric corrosion and oxidation at high temperatures and HNO_3; 4. Cr-Ni-alloys, resistant against atmospheric corrosion, oxidation at high temperatures, and HNO_3; 5. high Cu-containing bearing metals, very resistant against atmospheric corrosion and H_2SO_4; 6. Ni-Cr alloys, same as 3; 7. Si alloys, resistant against H_2SO_4; W alloys, resistant against corrosion and wear. The components are Al, Cr, Co, Cu, Mn, Mo, Ni, Si, W, C. Ha (4)

The So-Called "Non-oxidizing," Chemically Resistant Steels. (Les Aciers chemiquement resistants dits "inoxydables.") A. Portevin. *Revue Universelle des Mines,* Series 8, Vol. 7, Feb. 15, 1932, pages 198-223.

The various forms and causes of corrosion of steel are reviewed and the means so far used to reduce or eliminate this corrosion by addition of other materials are discussed. These additions must be, by nature, nobler, less liable to attack or passive by forming a protective film; they must be able to enter into solid solution with the steel. The latter property increases with the increase of the melting point of the alloyed elements and with the chemical proximity of these elements in the periodic system, and further with the similarity of the crystalline system. These items are treated in detail and the various forms of structure (martensitic, austenitic, etc.) explained in their relation to corrosion. The fields of application of rustless steels, particularly in the chemical industries are reviewed. Ha (4)

Dissolution Velocity of a Few Zinc-Silver Alloys in Acids. (Lösungsgeschwindigkeit einiger Zink-Silberlegierungen in Sauren.) M. Centnerszwer & M. Straumanis. *Zeitschrift für physikalische Chemie,* Vol. 156, Sec. A, Aug. 1931, pages 23-27.

It is found that Ag accelerates the dissolution velocity only if other, also accelerating additions, are present. In certain Zn-Ag alloys the velocity constant varies in the same magnitude as the molecular conductivity as required by the theory of local elements. Ha (4)

Corrosion by Underground Waters. N. Simpkin. *Iron & Coal Trades Review*, Vol. 124, Mar. 4, 1932, page 402; discussion, Mar. 25, 1932, page 513; *Colliery Guardian*, Vol. 144, Mar. 18, 1932, pages 538-540.

The extreme importance for mining operations of the quality of the water occurring underground is pointed out in its bearing on the equipment, pumps, fittings, pipes, boilers, etc. Especially dangerous is the liberation of hydrogen by the action of acid waters on steel pipes. Methods for overcoming the difficulties and resulting damage and danger are discussed at great length. VVK + Ha (4)

Pipe Line Corrosion and Soil Conductivity. *Engineering News Record*, Vol. 107, July 23, 1931, page 135.

Observations of corrosion, electric current and soil conditions on 9 pipe lines, made by the Bureau of Standards, led to the conclusion of a definite correlation between pipe corrosion and soil resistivity. Where soil conductivity is high, corrosion occurs. A method of measuring soil resistivity with 2 oak rods tipped with Fe, one carrying a small flash light battery and the other, a milliammeter with 100 milliampere scale was used. The rods are pushed down into the ground about 8″ apart. The soil resistivity was measured along pipe lines and all stretches in which the soil was abnormally conductive were found to be regions of corrosion trouble and, generally, of current departure. The soil resistivity at such places was usually below 500 or 600 ohms/ cm.^{3} With higher resistivities, no marked corrosion was found. Ha (4)

The Relative Corrodibilities of Ferrous and Non-Ferrous Metals and Alloys. Part III.—Final Report The Results of Three Years' Exposure at Southampton Docks. Newton Friend. *Institute of Metals, Advance Copy* No. 590, Apr. 1932, 8 pages.

Parts I and II appear in *Journal Institute of Metals*, Vol. 39, 1928, page 111 and Vol. 42, 1929, page 149. The bars were exposed at approximately half-tide level. The products of corrosion were removed and the corrodibility judged by the loss in weight. Results for 72 bars representing many ferrous and non-ferrous metals and alloys are given. Commercially pure Sn and Zn were not as resistant to corrosion as materials of lower purity. Brasses with the smallest grain size were the most resistant. Ni-Cu alloys offered great resistance to corrosion. An arsenical Cu was more resistant than As-free Cu. Tension, riveting, and cold working did not appreciably affect the resistance on Ni-Cr steels, but cracks appeared at welds in these steels. Some of the alloy steels exhibited localized corrosion. 9 references. JLG (4)

Comparisons of Electrolytic Deposits of Zinc and of Cadmium from Point of View of the Protection of Steel Against Corrosion (Comparison des dépots électrolytiques de zinc et de cadmium au point de vue de la protection de l'acier contre la corrosion). H. Figour & P. Jacquet. *Comptes Rendus*, Vol. 194, Apr. 25, 1932, pages 1493-1495.

The authors describe the results of a large number of systematic tests conducted with the view of determining the most satisfactory conditions for utilizing the 2 types of coating referred to in the title. Deposits were made upon plates of basic Bessemer steel containing 0.063% C. Variations were made in the methods of preparing the pieces before treatment, in the composition of the baths, and in the conditions under which electrolysis was carried out. Subsequent to coating, samples were submitted to 3 types of corrosion tests: (a) the salt spray at 15°-20° C., (b) warm, humid atmosphere, and (c) outside atmosphere. Corrosion was measured in 2 ways: (1) by the time of exposure after which there was a definite appearance of rust, and (2) by variations in the weight of the pieces. The results varied slightly, according to the method of producing the deposits. The results of the tests are given in 2 tables which are reproduced below. The results shown in the first table indicate that Cd offers better protection against corrosion than Zn in the salt-spray test and in the warm, humid atmosphere. In the atmospheric test, however, Zn proved to be better than Cd. It was noticed that a definite solution of the coatings, most pronounced in the case of Cd, occurred when the samples were exposed to the outside atmosphere.

Table I

Method of Corrosion	Nature of Deposit	Number of Hours of Exposure Prior to Appearance of Rust (Weight of Deposit) 200 mg./dm.^{2}	400 mg./dm.^{2}	600 mg./dm.^{2}	800 mg./dm.^{2}
Salt-spray	Cadmium	650	1075	1500	1740
	Zinc (B. cyanide)	200	960	1050	1300
	Zinc (B. sulphate)	155	615	945	1165
Warm, humid atmosphere	Cadmium	897	>5550	....	....
	Zinc (B. cyanide)	184	395	2087	2345
	Zinc (B. sulphate)	50	152	378	1525
Outside atmosphere	Cadmium	1056	1968	2736	5700
	Zinc (B. cyanide)	4416	10320	>11600	....

Table II

Method of Corrosion	Nature of Deposit	Increase of Weight (in mg./dm.^{2}) for an Exposure of 175 hr.	225 hr.	465 hr.	800 hr.
Salt-spray	Cadmium	28	30	36	43
	Zinc (B. cyanide)	32	37	73	103
	Zinc (B. sulphate)	31	42	98	148
Warm, humid atmosphere	Cadmium	25	27	30	36
	Zinc (B. cyanide)	65	77	115	150
	Zinc (B. sulphate)	70	89	140	......
		Diminution of Weight (in mg./dm.$_2$) for an Exposure of 550 hr.	1150 hr.	1680 hr.	2200 hr.
Outside atmosphere	Cadmium	40	143	212	266

The Corrosion of Iron; Protective Coatings. (La Corrosion du Fer; les Revetements Protecteurs.) M. R. Arzens. *Revue Fonderie Moderne*, Vol. 26, Feb. 25, 1932, pages 61-69.

The causes of corrosion and in particular of atmospheric corrosion are explained, the chemical transformations resulting from it for different metals and the corrosion products are described and various theories briefly discussed. The metal coatings for rust protection, oxides or salts, enamels, paints and coatings and the manner of preparation of the piece to be protected for the respective coatings are described in detail. 17 references. Ha (4)

Rust Protection of Cadmium Deposits. (Ueber die Rostschutzwirkung der Kadmiumniederschläge.) G. Buchner. *Oberflächentechnik*, Vol. 9, Apr. 1932, pages 80-81.

The paper gives the present views on the superiority of Cd plating as compared with galvanizing. The rust protective action of Cd deposits depends mainly on the nature of the metal on which the deposit is made, on the conditions of plating and the weight of the deposit per unit area. The critical thickness is about 350 to 450 mg./dm.^{2} which with a sufficient margin of safety would mean about 600 mg./dm.^{2} in practice and corresponds to a thickness of 0.0075 mm. All Cd deposits are at first porous and require a further treatment. Ha (4)

The Action of Sea-Water on Mild Steel. G. D. Bengough & A. R. Lee. *Iron & Steel Institute, Advance Copy* No. 3, May 1932, 17 pages.

An acid open-hearth steel containing 0.13% C, 0.15% Si, 0.034% P, 0.034% S, 0.46% Mn, 0.20% Ni, 0.04% Cr, 0.05% Cu and 0.02% O was used. Samples were completely immersed in stagnant sea water and in N/2 solution of NaCl at the constant temperature of 25° C. and under a pressure of 760 mm. Hg. The atmosphere in contact with the solutions was air, O_2, or A. The amounts of O_2 absorbed and the H_2 evolved were determined by ingenious methods. The weight loss was also determined. A large portion of the corrosion in sea water was found to be due to a reaction that liberated H_2, but in the absence of O_2, no H_2 was liberated even after 110 days immersion. The rate of corrosion in sea water was greater than in N/2 NaCl. The greater corrosion rate in sea water was a result of the reaction that liberated H_2. The rate of corrosion in sea water in contact with O_2 was only 20% greater than the rate in contact with air; in N/2 NaCl the rate is increased 2 or 2½ times by replacing air with O_2. It was not found possible to prepare a mixture of inorganic salts, with or without saponin, that would give the high rate of corrosion observed with sea water. The greater rate in sea water is attributed to the presence of organic matter in solution. Oxidation of sea water with permanganate decreased the corrosion rate. It is suggested that the evolution of H_2 may be an important factor in determining the adhesion of paints on steel immersed in sea water. 8 references. JLG (4)

A New Aluminum Light Alloy, Chlumin. Ichiro Iitaka. *Proceedings Imperial Academy*, Tokyo, Vol. 7, Apr. 1931, pages 161-164; *Journal Society Mechanical Engineers*, Japan, Vol. 33, 1930, pages 203-208.

Chlumin, an alloy of Al, Cr, Mg and Fe, is compared with some other well-known Al alloys in regard to its resistance to corrosion in NaCl solution and casting and rolling properties. WHB (4)

Corrosion Protection of Light Metals. (Korrosionsschutz von Leichtmetall.) L. Schiffer. *Deutsche Motorzeitschrift*, Vol. 9, Jan. 1932, pages 10-14.

In addition to the American Alclad and the German Allautal process of coating light metals by pure Al, a double coated Duralumin, designated as Duralplat has been brought on the market (German Patent 244,554) characterized by a corrosion resistant Al coated alloy subject to age-hardening (K 50). Micro-photographs are presented showing the intimate contact due to a diffusion of virgin metal and plate attained by thermal treatment. Enlargements of cross-sections of Brinell indentation marks (load 750, 1000 and 2000 kg.) are given to prove the favorable deep drawing properties of the plated surface layer which is uniformly deformed with the underlying carrier. The physical properties of Duralplat coincide with those of the Duralumin alloy 681: elongation = 15 — 18%, yield point = 26 kg./mm.^{2}, tensile strength = 38 kg./mm.^{2} Various kinds of corrosion tests in North Sea water and atmosphere showed after one year's exposure, that Duralumin lost 38% of the former elongation, 7% of its tensile strength, whereas Duralplat suffered only negligible losses of physical properties. Apart from the favorable bonding properties and the marked corrosion resistance, the resistance to mechanical wear, surface injuries, etc., are stressed in contrast to the soft surface of Alclad and Allautal. EF (4)

Intercrystalline Corrosion of Duralumin. A. J. Sidery, K. G. Lewis & H. Sutton. *Institute of Metals, Advance Copy* No. 598, Mar. 1932, 17 pages.

A short-time test for determining the susceptibility to intercrystalline corrosion was developed. In this test the Duralumin samples were immersed in a 1 *N* solution of NaCl containing 1% HCl by weight. The effects of overstraining on reaction to this test were examined. When overstrained by tension there was a slight tendency towards increased corrosion. When overstrained by compression there was a critical range of stressing, 14-17 tons/in.,^{2} which produced marked attack. From observations on samples quenched from various temperatures, it was found that those quenched from the higher temperatures were less subject to intergranular attack. Quenching in boiling water increased the tendency to intergranular corrosion. The rate of hardening at room temperatures of Duralumin quenched from various temperatures is shown in the form of curves. In general, the quenching temperature (between 470 and 520° C.) did not have a great effect on the subsequent hardening at room temperatures. 7 references. JLG (4)

Solubility of Carbon in Alpha Iron and Changes in Properties of Industrial Iron Produced by Heat Treatment under A_1 Point. (Sur la Solubilité du carbone dans le fer alpha et les variations résultantes des propriétés du fer industriel en cas de traitment thermique au-dessous du point A_1). E. Houdremont. *Revue de Métallurgie*, Vol. 29, Mar. 1932, pages 133-139.

The phenomena of C solution in α-Fe and the variations in properties produced by it and studied by Koester (Archiv für Eisenhüttenwesen, 2, 1929, pages 503-522) form a typical example of the precipitation hardening such as observed in duralumin. Studying the amount of C precipitated and held in solution using colorimetric C determination it was found that quenching above A_1 point has no effect on consequent hardening by aging. Quenched from 680° C. low C deep drawing steels did not stiffen when cooled in the furnace, responded to air hardening when sufficiently thin, and after water quenching and aging at 50° for 36 hours lost most of the deep drawing characteristics. Several day aging at room temperature produces the similar effect. The effect of age hardening is almost inversely proportional to the C content becoming undistinguishable at 0.6% C. JDG (5a)

Metallographic Investigations of Electric Welds. (Metallographische Untersuchungen von Elektroschweissverbindungen.) C. J. Hoppe. *Elektroschweissung*, Vol. 3, Apr. 1932, page 72.

The article summarizes the results of welding tests by Professor Paton, Kiew, Russia. The points investigated in particular are: (1) Effect of super-heating in welding on the structure and change of the mechanical properties of the base metal, (2) depth of the superheated structure of the base metal, (3) changes of the welded joints when subjected to loads (4) failures of weld seams. On the Equilibrium Diagram of Fe-Mo-C System. T. Takei. *Kinzoku no Kenkyu*, Japan, Mar. 1932, pages 97-124; Apr. 1932, pages 142-173.

By means of thermal, dilatometric and magnetic analyses as well as microscopic examination, the equilibrium diagram of alloys containing less than 6% C in the system Fe-C-Mo was constructed as in the figure. A ternary solid solution ω which has been formerly known as a double carbide, is formed by the peritectic reaction melt + $Mo_2C \leftrightarrow \omega$, and this phase forms eutectics with other binary phases. A maximum point P was found on the monovariant curve O_2O_3 and two ternary eutectic points at O_1 and O_3 respectively. The γ phase of Fe is only stable at high temperature and is decomposed by the peritecto-eutectoid reaction $\gamma + \omega \leftrightarrow Fe_3C + \alpha$ (Fe). γ solid solution does not coexist with ϵ (Fe_3Mo_2) phase. ϵ solid solution (FeMo) is stable only at high temperature and is decomposed by the eutectoid reaction as in the binary system. Another ternary phase ξ was often observable in high Mo and high C alloys but this phase has not yet been determined well. KT (5a)

The Magnetic Transformations of Ferro-Magnetic Metals (Die magnetischen Umwandlungen der ferromagnetischen Metalle). Rud. Ruer. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 205, Apr. 20, 1932, pages 230-234.

Recent tests which were carried out with an especially sensitive apparatus have not corroborated the views of Burgess and Crowe which have been held so far, that magnetization is a reversible process. Contrary to expectation, it was shown and confirmed by tests with different kinds of iron that the magnetic conversion at heating is different from that at cooling. This behavior can only be explained by the existence of a phase conversion, that is for an allotropic conversion of the usual type. Ha (5a)

The Application of the Polarization Microscope in the Study of Copper Alloys. (Die Anwendung des Polarisationsmikroskopes bei der Untersuchung von Kupferlegierungen.) M. v. Schwarz. *Zeitschrift für Metallkunde*, Vol. 24, May 1932, pages 97-103.

On the Question of the Allotropy of White Tin and the Equilibrium Diagram of the System Tin-Cadmium. Y. Matuyama. *Kinzoku no Kenkyu*, Jan. 1932, pages 1-32 (Japanese); *Science Reports Tohoku Imperial University*, Vol. 20, 1931, pages 649-680.

The allotropy of white Sn at 150°-200° C. was studied by means of several physical methods of high sensitivity. The result of measurement of electric resistance of pure Sn during cooling from melt (the cooling velocity 0.7° C./min.) showed no abrupt change in the resistance-temperature curve, but was very smooth. In the differential dilatometric measurements no discontinuity or break was observed, the neutral body being pure Ag. The sensitivity of this measurement was nearly 1/530,000. A differential thermal analysis showed also no irregularity, the neutral, in this case, being pure Cd. A silver constantan thermocouple was used for the differential couple, and a platinum gold-palladium couple for the temperature measurement of the specimen. The sensitivity of the apparatus for temperature measurement was such that 1 mm. of the scale deflection corresponds to 1/235° C. In the measurement of the thermoelectromotive force of the couple Cu-Sn, no abrupt change was observed. In X-ray analysis, spectrums were taken at room temperature and at 152-163° C., passing a constant current of 2.1 to 2.2 ampere through the specimen, and also at 220-223° C., the 3 spectrums were identical. From those results it was concluded that Sn has no transformation at a high temperature. Sn-Cd alloys were also studied by the same physical methods and offered an equilibrium diagram shown in the figure. The eutectoid transformation at 130° C. is not caused by the transformation of Sn, as it has often been assumed to be. Cd is soluble in Sn up to ½% at room temperature. The Shapes of Growth of Metallic Crystals. (Die Wachstumsformen von Metallkristallen.) G. Tammann & K. L. Dreyer. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 205, Apr. 8, 1932, pages 77-80.

How the shape of a crystal and its growth is influenced was observed by the separation of a metal from a mixture of 2 metals with widely different melting points, for instance, Cu-Bi, Ag-Pb, Zn-Pb. By changing concentration and cooling velocity the separation temperature and separation velocity can be influenced. A few drawings are given showing the shapes of crystals as they change under different conditions; the former view that crystals can only occur in polyhedric forms is not tenable, as the surface tension can at sufficiently high temperature overcome the strength of the crystal and round off its edges and corners. Ha (5a)

The Velocity of the Displacement of the Grain Borders in the Primary and Secondary Recrystallisation of Aluminum. (Die geschwindigkeit der Korngrenzenverschiebung bei der primären und sekunderen Rekristallisation des Aluminiums.) G. Tammann & K. L. Dreyer. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 191, July 7, 1930, pages 69-73.

The average number of crystals/mm.² which are formed in cold-rolled Al after annealing at 600° C. decreases from 120 after the first minute to 35 within 30 min. and after this time only little with further annealing; this is due to a continuous fine film surrounding the grains. The average linear velocity of the displacement of the grain borders decreases after the first minute from 0.0185 to 0.00011 mm. after 30 min. and to 0.0000076 mm. after 120 minutes. The direction of growth greatly influences the velocity of growth and depends also on the duration of annealing. Ha (5a)

A Study of Common Soft and Dead Soft Steels From the Point of Dilatometric Anomalies. (Etude sur des aciers ordinaires doux et extra doux notamment au point de vue des anomalies dilatométriques.) J. Seigle. *Revue de Métallurgie*, Vol. 29, Apr. 1932, pages 169-182; May 1932, pages 252-258.

Dilatation curves taken with Chevenard dilatometer having mechanical recording device on many low C steels made by 6 different methods showed that the shape of the curves might be very different particularly in regard to the A_3 point. It is affected by P content higher than 0.10%, long heating at red heat particularly in an atmosphere of hydrogen and twisting at a red heat. The orientation of specimens in regard to rolling and the gas content of steel do not seem to have any influence on the shape of the curves. See also *Metals & Alloys*, Vol. 3, May 1932, page MA 121. The Application of the Law of the Sum of the Heights in an unequilateral Triangle to Calculations in Melting Technique. (Die Anwendung des Höhensummensatzes eines ungleichseitigen Dreiecks auf schmelztechnische Berechnungen.) U. Retzow. *Die Metallbörse*, Vol. 21, June 13, 1931, pages 1107-1108; June 20, 1931, pages 1155-1156.

The utilization of the height-sum law (graphical representation of three quantities the sum of which remains constant) for the determination of the behavior of ternary compounds is dealt with in a lecture before the 91st Naturforscher Versammlung, Königsberg, 1931. Two applications are given as examples: one of which refers to a binary Sn solder and the other to a ternary Bi-Pb-Sn alloy. The graphical solution is given in detail. EF + Ha (5a)

The Transformations of Metals. (Ueber die Umwandlungen von Metallen.) Alfred Schulze. *Zeitschrift Verein Deutscher Ingenieure*, Vol. 76, Jan. 30, 1932, pages 108-112.

The transformation of metals, that is the change from one modification to another of a solid material without any change in their chemical composition, has been observed in many metals and is of great importance in explaining the nature of refining. The behavior of Fe, Tl, Ni, Co, Mn, Sn, Sb and Zr which possess distinct critical points is discussed; metals not having a critical point although formerly supposed to have, are Al, Zn, Cd, Bi, Si, Ge, Ti. The reasons for such non-existence are discussed; curves are reproduced. 63 references. Ha (5a)

On a Self-Recording Dilatometer for Quenching and the Mechanism of Nodular Troostite Formation in Carbon Steels. S. Sato. *Kinzoku no Kenkyu*, Apr. 1932, pages 174-188 (In Japanese); *Science Reports Tohoku Imperial University*, Vol. 20, 1931, pages 260-267 (In English).

A new self-recording apparatus for taking thermal expansion-temperature curves during quenching was designed. The form of curves recorded by the apparatus shows the degree of quenching efficiency of the media. During the quenching of a carbon steel, the austenite begins to be transformed into martensite at about 200° C. or at a still lower temperature in the case of oil quenching, but in the case of a more severe quench, such as water quenching, the transformation begins to take place at markedly higher temperatures, i. e., at about 300° C. The martensite expansion or the development of martensite during water quenching is greater than in the case of oil quenching. This is in good agreement with the fact that the amount of retained austenite in quenched steel is greater in the case of oil quenching than in water quenching, and also in view of the fact that the austenite $\rightarrow$ martensite transformation is much facilitated by an internal stress caused by quenching which is greater in the case of water quenching than in the case of oil quenching. The author also found that a very thin coating of fine clayey particles on the surface of the specimen considerably favored the quenching action. The author named this coating "facing." The favorable effect of the facing in obtaining a uniform quenching of the specimen is probably due to the prevention of a direct contact between the highly heated steel surface and water or oil, a rapid formation of vapor on the surface of the specimen being thereby avoided. Since the change of austenite into martensite is accelerated by internal stress, it may be expected that during the transformation, the martensite will first be formed at several centers on the grain boundary of the mother austenite, because owing to the impurities present in the steel, the crystal lattice on the boundary is much more distorted than the lattice within the grains themselves. Consequently, when the lowered Ar_1 transformation begins to take place at 500°-600° C., some portion of the austenite at several spots on the grain boundary will be first transformed into martensite. The martensite is immediately decomposed into cementite and Fe, and as this change being accompanied by recrystallization, the characteristic pattern of martensite is destroyed. This process starts from various points where the stress is especially great and extends in every direction independent of the orientation of the austenite, resulting in a structure which we call nodular troostite. In the case of a rolled and quenched specimen a banded troostite is sometimes observed, which is attributed to the mode of distribution of impurities. KT (5a)

The Segregation Problem. (Zum Kornseigerungsproblem.) E. Scheuer. *Zeitschrift für Metallkunde*, Vol. 23, Aug. 1931, pages 237-241.

The segregation accompanying the freezing of a liquid alloy exhibiting complete miscibility in the liquid state but only partial miscibility in the solid state is studied mathematically and experimentally. Upon the assumption of immediate diffusion in the liquid state and of the absence of diffusion in the solid state during the freezing process, the following equation for segregation is developed: $l = \left(\frac{c}{y}\right)^{\frac{p}{p-1}}$, where l = quantity of remaining melt, c = original composition of melt in second metal, y = composition of remaining melt in second metal, and p = distribution coefficient of second metal between melt and separated solid. Equations are developed for the additional cases in which p is not a constant: (a) when p is a linear function of y, and (b) when p is a quadratic function of y. The application of these equations to segregation in alloys of Al with Cu, of Al with Zn, of Cu with Zn, and of Cu with Sn was studied experimentally. It was found that the α solid solutions of Cu in Al and of Sn in Cu form from a melt with almost no diffusion in the solid state, but that the α solid solution of Zn in Al forms with appreciable and that of Zn in Cu with almost complete diffusion in the solid state. Structure & X-Ray Analysis (5b)

A Gas X-Ray Tube for Crystal Structure Analysis. H. Kersten. *Review of Scientific Instruments*, Vol. 3, Mar. 1932, pages 145-150.

The necessary intensity of X-ray beams for crystal structure analysis was obtained by providing sufficient cooling to allow for large current carrying capacity by making use of cellophane windows and by placing the slit in the evacuated system so that a close approach to the target is possible. The construction is described in detail and a few Laue-pattern photographs illustrate the results obtainable. Ha (5b)

The Mechanism of the Allotropic Transformation of Cobalt and Thallium. (Ueber den Mechanismus der allotropen Umwandlung von Kobalt und Thallium.) U. Dehlinger. *Metallwirtschaft*, Vol. 11, Apr. 15, 1932, pages 223-225.

10 references. Similar to Co, Tl has a hexagonal lattice which changes to a face centered cubic at 231° C. By slow cooling from a melt large hexagonal single crystals of Tl were obtained which broke up after heating above 230° C. and cooling. This shows that a cubic single crystal must first have been formed from the melt. In the cubic to hexagonal transformation that plane of the 4 crystallographically equal ones is preferred which is most nearly parallel to axis of the rod, because thereby the least surface enlargement occurs. The energy necessary to produce a transformation increases with decreasing grain size and with a grain size of .1 μ the energy is of the order of the total transformation heat. It is proved by thermodynamics that thereby a temperature hysteresis occurs, that the temperature of the cubic to hexagonal transformation is considerably lowered independent of the rate of cooling. The temperature drops to such an extent that the diffusion processes at the grain boundaries which are necessary for the transformation to take place cannot proceed noticeably. In this way the transformation can be completely prevented, in the same manner as with rolled sheets and small grained powder of Co. CEM (5b)

The Formation of Superlattices in Alloys of Iron and Aluminum. A. J. Bradley & A. H. Jay. *Proceedings Royal Society*, Vol. 136A, May 1932, pages 210-232; *Iron & Steel Institute Advance Copy* No. 4, May 1932, 19 pages.

A quantitative examination has been made of the intensities of the lines of a series of powder photographs of alloys of Fe and Al in the range Fe-FeAl. All the alloy structures are primarily based on a simple body-centered cubic lattice like that of α-Fe, but a detailed examination of alloys in the annealed and quenched states gave widely differing results. Alloys quenched from 900° C. and above show a random distribution of atoms up to 25 atomic % Al. Between 25 and 26% Al there is an abrupt change in structure and cubic centers differ in composition from cube corners. The intensity measurements show that in the quenched alloys with ordered arrangement one set of positions is occupied only by Fe atoms, but the other set contains Fe and Al atoms in varying proportions depending on the alloy composition. Annealed alloys with less than 18% Al have a random distribution, and from 40% to 50% they have the FeAl type of structure exactly like the quenched alloys in this range. At intermediate compositions a new type of structure appears which is of the type Fe_3Al. In the Fe_3Al arrangement the Al atoms lie on a face-centered cubic lattice forming a superlattice with dimensions twice as great as those of the small body-centered cube. Intensity measurements have been used in order to follow out in a detailed manner the process of the building up and decay of the Fe_3Al structure. There is no precise composition at which the Fe_3Al structure can be said to begin or end, and the structure is not completely realized even at the theoretical composition. JLG + WAT (5b)

X-Ray Studies on Bi Single Crystals. A. Goetz & R. C. Hergenrother. *Physical Review*, Vol. 40, Apr. 1932, pages 137-150.

An X-ray analysis of different types of Bi single crystals is described in order to decide whether or not the difference in density, electric conductivity and thermal e.m.f. observed between Bi crystals grown within or outside of a transverse magnetic field were caused by a change in lattice spacing or due to an alteration of the lattice parameter. The Bi crystals were grown by the method described by Goetz, and the cleaved planes (111) and $(1\bar{1}1)$ were used. Two different methods have been used to measure the integrated reflected intensities for different orders. By means of a new photographic method the intensities of the first to the fifth order have been compared and no consistent change of the parameter could be found. In addition to the photographic records an ionization method of high sensitivity has been used involving a new type of X-ray spectrometer—designed by Hergenrother—in connection with a Hoffman electrometer. The photographic results were verified and the integrated intensities could be measured up to the seventh order, thus permitting much greater accuracy in the determination of the parameter than has been previously reported. Making use of Pauling and Sherman's computations of the atomic structure factor and applying an experimentally determined value of the Debye factor, the parameter along (111) was found to be 0.359 A. U. $\pm$ 0.0006 A. U. which value lies well within the limits of Hassel and Mark and is slightly larger than James' observation. The non-existence of a change in lattice structure and in parameter for the crystals grown within and outside of a transverse magnetic field shows that the electric volume effects which distinguish the 2 types of crystals can exist in spite of the unchanged conditions for the existence and distribution of the "free" electrons as given by the geometric configuration of the atoms in the lattice. Hence the cause of these effects can only be ascribed to changes of certain variations in the lattice, the period of which must be many times larger than the size of an elementary rhomboheder in order to be undetectable to X-ray analysis. This implies the assumption of very large "mean free paths" for the electrons in a crystal. WAT (5b)

The Molecular Process of Crystal Growth in Hexagonal Metals. Deposition upon Monocrystalline Hemispheres of Zinc. Paul A. Anderson. *Physical Review,* Vol. 40, May 1932, pages 596-606.
The growth of a single crystal rod of Zn is allowed to proceed from a small orifice into a mass of molten Zn and the monocrystalline hemisphere thus formed isolated by rotation of the apparatus. The hemisphere is subjected to uniform bombardment by Zn vapor and observation of the growth on its surface forms the basis of a study of the variation of depositional rate with crystal surface structure. It is assumed, with Kossel and Stranski, that the force acting upon an atom which has struck the crystal surface is qualitatively proportional to the number of contiguous lattice atoms and a "force series" is drawn listing the relative depositional energies for 11 typical positions of different surface structure. With the aid of this force series the macroscopically observed growth on the experimental crystal is interpreted in terms of atom-by-atom deposition. WAT (5b)

The Dependence of Tamman's Resistance Limits on the Crystallographic Orientation. (Zur Frage der Abhängigkeit der Tammannschen Resistenzgrenzen von der kristallographischen Richtung.) R. Glocker & L. Graf. *Metallwirtschaft,* Vol. 11, Apr. 15, 1932, pages 226-227.
16 references. Single crystals of Au-Zn alloys were prepared by melting pure Au and Zn in graphite crucibles in an atmosphere of CO_2. After X-ray examination of the 6 mm. diameter rods, specimens were chosen which were so oriented that in one case the surface of the cube, in the other the surface of the dodecahedron was exposed. Single crystals containing 52 atomic % of Au with body centered cubic lattice and regular atom distribution were treated with concentrated HCl with and without N oxides, with concentrated HCl and H_2O_2 and with aqua regia for several days. The two surfaces, containing different proportions of noble and base metals, were equally resistant to these reagents. From this result the general deduction is made that in all binary lattices in which the coördination group of the first sphere always consists of only one kind of atoms the resistance limits are independent of the crystallographic direction of the attack of the solvent. CEM (5b)

X-Ray Examinations in Practice. (Röntgenuntersuchungen im technischen Grossbetrieb.) A. Herr. *Die Werkzeugmaschine,* Vol. 36, Jan. 15, 1932, pages 1-3; Jan. 30, 1932, pages 27-28.

Procedure for the Notched Tensile Test. (Die Praxis des Kerbzugversuchs.) W. Kuntze. *Metallwirtschaft,* Vol. 11, Mar. 25, 1932, pages 179-184.
Contains 5 references. Only 3 cornered notches of variable notch angle and notch depth are considered. The ends of the test bars can be either smooth, threaded or slotted. The diameter of the bar should be not over 10 mm. and its length 50 mm. for small notch angles and 70 mm. for large notch angles. The radius at the point of the notch should be .1 to .15 mm. To obtain correct and consistent results it is of utmost importance that the test bars are properly machined. The notch should be machined after the rest of the machining has been completed and the bar should be held in a chuck, not between centers. The free end of the bar must not be stressed during machining and good clearance for the cuttings is necessary. It is best to use comparatively high cutting speeds. Examples are given of the inconsistent results obtained when the machining operations are not properly carried out. However, with correctly prepared test bars the results are more consistent than in regular tensile tests. A special gage with thin pointed blades is used to measure the diameter of the notch and special holders which are suspended from centers are used to hold the test bars in the testing machine. CEM (6)

Radiographic Tests of Cast Metal and of Welds. H. H. Lester. *Engineers & Engineering,* Vol. 47, Apr. 1930, pages 77-80.
Advocates the systematic testing of castings and welds by examination of X-ray photographs and describes the beneficial application in U. S. Arsenal, Watertown. Good welding technique was achieved by correlation of various methods and the results of X-ray examination and rendered possible the extended use of welding. Some of the more common defects are explained and discussed. Ha (6)

The Upper and Lower Yield Points in Steel Exposed to Non-Uniform Distributions of Stress. G. Cook. *Engineering,* Vol. 132, Sept. 11, 1931, pages 343-345.
Contribution to the Report of the Committee on Stresses in Overstrained Materials, presented to Section G of the British Association, London, Sept. 30, 1931. See *Metals & Alloys,* Vol. 3, June 1932, page MA 168. LFM (6)

Magnetic Measurements on Rhenium. (Magnetische Messungen am Rhenium.) W. H. Albrecht & E. Weber. *Die Naturwissenschaften,* Vol. 19, Jan. 2, 1931, pages 20-21.

Magnetic measurements on chemically pure Re (less than 0.01% impurity) gave a spec. susceptibility at 18° C. of $\chi = + 0.046 \times 10^{-6}$ ($\pm$ 0.02) whereas rhenium perrhenate proved to be diamagnetic, yielding $\chi = - 0.13$ ($\pm$ 0.05) at 18° C. The Re values do not lie between the neighboring elements Os ($+ 0.074 \times 10^{-6}$) and W ($+ 0.33 \times 10^{-6}$). EF (6)

Resistance of Steels to Repeated Impacts (Résistance des Aciers aux Chocs Répétés). L. Grenet. *Aciers Spéciaux, Métaux et Alliages,* Vol. 7, Mar. 1932, pages 82-92.

Tests were made on the following steels:

	C	Mn	Si	P	S	Cr	Ni
No. 1 Low C Steel	0.12	0.40	0.15	0.019	0.009	......	......
No. 2 2% Ni-steel	0.12	0.45	0.13	0.18	0.016	......	2.10
No. 3 C Steel	0.31	0.59	0.32	0.045	0.032	......	......
No. 4 Ni-Cr steel	0.23	0.50	0.25	0.015	0.016	0.76	2.93
No. 5 Air hardening Ni-Cr	0.40	0.50	0.25	0.005	0.014	1.32	3.74
No. 6 5% Ni-steel	0.15	0.32	0.30	0.02	0.015	0.55	5.20

These tests showed that heat treatment of steel prior to its testing does not improve the resistance to repeated impact. No relation could be obtained between the elastic limit and the resistance to repeated impacts. GTM (6)

Wall Thickness and Bending Strength of Cast Iron. (Wandstärke und Biegefestigkeit des Gusseisens). Hans Jungbluth & Paul A. Heller. *Archiv für Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 519-522.

Results from the literature on transverse tests of cast iron bars of varying diameter were re-computed by 3 equations to obtain comparative data:

$$\frac{\sigma'_B}{\sigma'_B(d = 30)} = \left(\frac{d}{3}\right)^{-0.284} \qquad (1)$$

$$\frac{f\ (d)}{f\ (d = 30)} = \left(\frac{d}{3}\right)^{1.09} \qquad (2)$$

$$\varepsilon = \frac{\sigma'_B \times 1_s}{6\,E \times D} \qquad (3)$$

The equations afford simple means for critically examining various data on deflection tests. Strain number is especially useful, for, besides acting as reliable indicator of wall thickness—sensitiveness, also distinguishes cast iron quality. Transverse section—sensitiveness of cast iron serves for deflection requirements if arrangement of material is given by a Maurer cast iron—diagram. As an example of computing transverse test data on cast-iron bars of various diameters by the simplified comparative scheme, the authors use J. L. Jones' results published in *Proc. A.S.T.M.,* Vol 28, 1928, Part 1, pages 142-143.

Optical Polarization Tension Tests on Unsymmetrically Bent Corners and Double Bends. (Polarisationsoptische Spannungsuntersuchungen an unsymmetrischen Stabecken und an Doppelhaken.) L. Kettenacker. *Forschung auf dem Gebiete des Ingenieurwesens,* Vol. 3, Mar.-Apr. 1932, pages 71-78.

The tension ratios in curves of unsymmetrical pieces loaded for bending were investigated experimentally. In obtaining the increase in tension by calculation, an empirical formula, based on the results of numerous tests, was obtained for practical purposes. This formula can also be applied in calculating tensions on other sides and for other loads where it refers back to a simple case of the tension at the curve. Similarly, in cases of simple and momentary loading, the network of isolines and main tension spectra are obtained. The latter are particularly important, especially for use in placing reinforcements in reinforced concrete structures. In the second part of the experiment, an optical tension test on double bends was carried out. A comparison of the values of tensions obtained experimentally with the values used in ratios for sharply bent pieces indicates a remarkable co-ordination of the two. MAB (6)

New Apparatus for the Brinell Ball Test. (Nouvel Appareil pour l'Essai à la Bille de Brinell.) Guillery. *Genie Civil,* Vol. 98, Mar. 28, 1931, page 328.

Description of an improved Brinell hardness testing machine given to the Association for Testing Materials, Mar. 1931. The machines measure automatically the diameter of the impressions. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 256. Ha (6)

Tests on Tin-Base and Lead-Base Bearing Metals. C. Jakeman & Guy Barr. (National Physical Laboratory). *Engineering,* Vol. 133, Feb. 12, 1932, pages 200-202.

Condensed from British Non-Ferrous Research Association; Research No. 43, Research Reports, Association Series, No. 289 A, Nov. 1931. Object of the research was to determine the comparative chemical action of lubricants on Sn-base and Pb-base bearing metals. A complete description is given of the apparatus used and the results are presented in tabular form. Results show that an alkali metal-Pb alloy will run satisfactorily at moderate loads and temperatures when lubricated with mineral oil or compounded oil, but that the alloy dissolves freely in olive or sperm oils. Neither high-Pb nor high-Sn alloys are readily attacked by mineral oil, compounded mineral oil or castor oil, but generally speaking, a higher friction loss will occur with a high-Pb alloy than with a high-Sn alloy. LFM (6)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Pitting in Nickel Solutions. W. M. Phillips. *Monthly Review, American Electroplaters Society,* Vol. 19, Apr. 1932, pages 9-11.

Paper before Chicago Branch Annual Meeting, Feb. 27, 1932. Pitting is due to dirt particles which act as insulators over small areas on which they rest. At such points the cathode potential is reduced below that of Ni deposition, but not below that required for deposition of H, Fe^{++} or Cu, if the latter metals are present in the bath. Hydrogen peroxide raises the hydrogen overvoltage and prevents H bubbles forming, thus eliminating pitting. It also oxidizes Fe^{++} to Fe^{+++} and Cu, and prevents them from depositing on the cathode and forming pits. LCP (7a)

Procedure in Plating Rolled Zinc and Zinc Die Castings. *American Machinist,* Vol. 75, Nov. 5, 1931, page 723.

Chart indicates briefly the methods and formulas of solutions used. RHP (7a)

Nickel and Chromium Plating of Aluminum Castings. (Die Vernickelung und Verchromung von Aluminiumguss.) *Deutsche Motorzeitschrift,* Vol. 8, Dec. 1931, page 418.

This note decidedly denies that Al castings could not be Ni and Cr- plated. However, scrap metal frequently remelted is unsuited due to the presence of oxides and pores. A dense casting is a pre-requisite for the successful plating operation thus restricting the use of sand castings. EF (7a)

The Structure of Nickel Deposits. (Das Gefüge der Nickelniederschläge.) Eugen Werner. *Oberflächentechnik,* Vol. 9, Apr. 19, 1932, pages 77-78.

With the present trend to rapid methods of electroplating the proper, very careful preparation of the work regardless of kind of metal, and of proper treatment and composition of the electrolytic baths is of utmost importance. A few illustrations show the most recurring defects starting formation of rust or corrosion, and hints are given to avoid them. Ha (7a)

Hot Nickel Solutions and Low pH. Alex. Regmunt. *Monthly Review, American Electroplaters Society,* Vol. 19, May 1932, pages 15-21.

Paper before Los Angeles Branch Annual Meeting, Mar. 12, 1932. Operating details for applying Ni-Cu-Ni coating to steel bumper bars to a thickness equivalent to 200-300-400 ampere-minutes respectively. The Ni bath contains 2.5 N. Ni, 0.21 N. Cl, 0.45 N. H_3BO_3 at pH of 4.0-5.4. Temperature 115° F. and current density 35 amp./ft.² Details of chemical control of all baths used are given. LCP (7a)

High Temperature Chromium Plating. A. Willink. *Monthly Review, American Electroplaters Society,* Vol. 19, Jan. 1932, pages 40-49.

Includes discussion. Paper before Philadelphia Branch Annual Meeting, Nov. 21, 1931. The author claims it is more economical to do Cr plating at 160° F. than at 100-135° F. The advantages are (1) wider plating range, (2) better throwing power, (3) increased current efficiency, (4) faster rate of plating, (5) less need for accurate control, (6) reduction of surface film of oxide during plating, (7) less porosity in deposit, and (8) harder deposit. The disadvantages are (1) larger generator required, (2) greater heating facilities required, and (3) difficulty of using stopping off materials. The bath used contains CrO_3 250 g./L., SO_4 2.5 g./L. LCP (7a)

The Chromium Plating of Pure Aluminum and Aluminum Alloys. (Das Verchromen von Reinaluminium und Aluminium-Legierungen.) K. Altmannsberger. *Aluminium,* Vol. 12, Apr. 31, 1930, pages 5-6; *Korrosion und Metallschutz,* Vol. 7, July 1931, pages 172-173.

The objects are first plated with Zn, then with Ni and finally with Cr. Conditions of deposition are discussed. See *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 245. Ha (7a)

Chromium Plating Literature, (III) L. H. Decke. *Brass World,* Vol. 28, Apr. 1932, pages 74-75.

This instalment deals with analysis. WHB (7a)

Adhesion of Electrodeposited Nickel to Brass. A. W. Hothersall. *Preprint, Journal Electroplaters & Depositors Technical Society,* May 1932, pages 115-141.

Adhesion of Ni electrodeposit on Cu and brasses was tested (1) qualitatively by pulling the deposit, not less than 0.03 inch thick with pliers, and (2) quantitatively by "Ollard Test" (*Transactions Faraday Society,* Vol. 21, 1926, page 81) in terms of tons/in.² Adhesion was then found to vary according to the nature of the brass surface. While a relatively high adhesion was obtained to filed or machined brass surface, only a slight degree of adhesion, such that the deposit could be pulled off with the fingers, was found in the case of "emeried" brass. The results obtained by the tests do not indicate the true adhesion as the test pieces invariably failed in the surface layers of the brass and not at the Ni-brass interface. In the majority of cases, heat treatment of the Ni coated specimens at 250° C. for 2 hours was found to improve very considerably the degree of adhesion of Ni deposit both on surfaces not etched during cleaning, and on a Cu under-coating from the acid sulphate bath. By these methods fairly strong adhesion was obtained on "emeried" brass. The degree of adhesion was found to increase gradually with the degree of etching, and it is concluded that the poor adhesion of electrodeposited Ni which occurs on unetched emeried brass is due partly to embrittlement of the surface layers by adsorption of hydrogen and partly to the inherently weak condition produced by the emery treatment. In the case of buffed brass, it has been found that the material which is particularly weak inherently, and which is principally susceptible to hydrogen embrittlement, is confined to an extremely thin surface skin, probably less than 0.0005 mm. in thickness and that removal of this skin by means of etching treatment before deposition of Ni produces adherent deposits. Etching by means of mixed acids containing HNO_3 cannot be controlled satisfactorily. Anodic etching for 30 seconds and 10 amp./ft.² in KCN, 50 g./L., or in citric acid, 20 g./L. and ammonium citrate, 6 g./L., renders polished brass surface sufficiently etched to ensure adhesion without noticeably dimming the lustre. LCP (7a)

INDUSTRIAL USES & APPLICATIONS (9)

Aluminum Transmission Lines in Italy. (Aluminium-Oberleitungen in Italien.) *Elektrotechnische Zeitschrift*, Vol. 53, Apr. 14, 1932, page 365.

The Italian State Railways intend, in order to promote the Italian Al industry, to use Al-steel wires, with a ratio of section of steel to Al of 1:4.29. About 100 miles have already been equipped with it. The elasticity modulus of these wires is 8500 kg./mm.²; there are 30 wires of 2.7 mm. around a core of 7 steel wires of 2.7 mm., the outer diameter is 19.1 mm.; weight 0.481 kg./m., elastic limit 5100 kg./mm.², service load 1850 kg./mm.² and resistance at 20° C. 0.162 ohm./km. On another part of the lines a wire of Al alloy (Al 98.7%, Si 0.6%, MgO 4%, FeO 3%) with an electrical conductivity of 31.5 against 35 for pure Al is used. The saving in weight amounts to 55% so that this alloy is particularly suitable for long spans. The wire consists of 37 strands of 2.6 mm. The outer diameter is 18.5 mm., weight 0.558 kg./m., resistance 0.155 ohm./km., and service load 1675 kg. Joints are made of Al alloy. Ha (9)

Steel Pile Bulkhead Wall Retains Deep-Water Fill. *Engineering News-Record*, Vol. 108, Mar. 31, 1932, pages 468-470.

Use of long steel sheetpiles for deep lake seawall is unusual and new. Seven million cu. yd. fill adds 365 acres to Lincoln Park, Chicago. CBJ (9)

Brick-On-Metal Base Fails on Illinois Test Road. *Engineering News-Record*, Vol. 108, May 12, 1932, pages 694-696.

Brick pavement on sheet metal base constructed in 1930 near Springfield, Ill., has recently been destroyed and replaced. Brief description of the pavement is given, more complete details were in the Engineering News-Record, Oct. 2, 1930, page 523. The results of the experiment indicate that a bituminous-filled brick surface must be constructed on a rigid base. Flexible bases cause loosening of the bituminous filler, thereby admitting surface water and ultimately resulting in the destruction of the mastic cushion. CBJ (9)

Charging Boxes and Buggies Built of Welded Plates. *Steel*, Vol. 90, Jan. 11, 1932, page 26.

A description of the new welded steel plate charging boxes and charging box buggies in use at the open-hearth plant of the Lukens Steel Co., Coatesville, Pa. JN (9)

Designs Promote Steel Use in Residence Construction. *Steel*, Vol. 90, Jan. 25, 1932, pages 26, 28.

The construction of three different types of steel residences is being undertaken in the Cleveland district. The first frameless steel house constructed entirely of welded steel sheets, will be erected by the American Rolling Mill Co. The entire house, consisting of 8 rooms, 2 baths and a 2-car garage, will require only 14 tons of steel sheets, 16 to 20 gage, consisting of less than 100 partially assembled pieces. The exterior will be covered with asbestos sheet and the interior with Masonite insulation board. J. A. Altschuler has applied for patents on the design of a residence made up of steel units fabricated in the shop and assembled on the site by means of properly concealed steel bolts. The outside may be finished in brick, tile or stucco and the inside may be plastered and then covered with paint or paper. The Ferro Enamel Corp. will erect an 8-room residence constructed entirely of porcelain enamel on steel. JN (9)

Copper Pipe for Gas Distribution. Arthur F. Bridge & Frederic A. Hough. *American Gas Journal*, Vol. 136, May 1932, pages 48-49; *Gas Age-Record*, Vol. 69, Apr. 23, 1932, pages 503-513.

With present day construction methods Cu and steel are about equal in gas tightness. The life of gas mains depends upon varying conditions so that in certain conditions steel pipe is superior and in other conditions Cu alloy pipe will surpass. For economic calculations 30 years is assumed for the life of Cu alloy although in cases where only soil corrosion is the limiting factor, a much longer life will usually be realized. Cu pipe is probably unsuited for underground pipe in areas where stray current electrolysis is severe. Cu pipe should not be used to distribute gas containing as much as 1 grain of H_2S/100 ft.³, unless the gas is dry. CBJ(9)

New Avenues for the Use of Tin. Jerome J. Collins. *Mining Journal*, London, Vol. 177, Apr. 16, 1932, page 257.

2Fe (solid) + $3SnCl_2$ (molten) = Fe_2Cl_6 + 3Sn (molten). The Sn is deposited on the Fe, suggesting the possibility of tinning irregular manufactured articles. $SnCl_2$ can be purified by the reaction $SnCl_2 + Cl_2 = SnCl_4$, $SnCl_4 + Sn = 2SnCl_2$. On cooling the solution, $SnCl_2.2H_2O$ crystallizes. The H_2O of crystallization is evaporated, leaving molten $SnCl_2$. On electrolysis Sn is deposited at the cathode and $SnCl_4$ at the anode. The $SnCl_4$ melting at 33° C, boiling at 114° C, is highly deliquescent. H_2O can be added to it (not vice versa) to 1 part $SnCl_4$ in 5000 without hydrolysis. It can be used as an antiseptic, as a weed killer, and as a substitute for $AlCl_3$ in petroleum cracking. AHE (9)

Welded Structures, Castings and Forgings Compared. R. A. Bull. *Iron Age*. Vol. 128, Dec. 24, 1931, pages 1620-1622.

Abstract of a paper read before the National Steel Founders' Association at New York. It reviews critically the characteristics of various classes of castings, of forgings and of welded structures. See "The Selective Application of Castings," *Metals & Alloys*, Vol. 3, July 1932, page MA214. VSP (9)

Piccard's Gas-Welded Aluminum Gondola. (Die autogen geschweisste Aluminium Kugel von Piccard.) *Zeitschrift für Schweisstechnik*, Vol. 21, July 1931, page 162.

The Al-gondola of Prof. Piccard's stratospheric balloon was made of 3.5 mm. Al sheets and assembled by gas welding. Diameter was 2.1 m. EF (9)

Large Uses of Steel in Small Ways. 209th. Article. Warm Air Furnaces. *Steel*, Vol. 90, Jan. 25, 1932, page 30.

The production of warm air furnaces in the United States consumes 74,000 tons of steel annually, averaging 318 lbs. for each installation. About 15% of all furnaces built are of all-steel construction. The superiority of steel vs. cast iron "stoves" for furnaces is still a matter of controversy. The further development of air conditioning furnaces promises a greater outlet for the use of steel. These furnace units filter the air, heat it in winter, and regulate the relative humidity of the air before circulating it through the building. In summer, the air may be filtered, humidified and circulated without heating. JN (9)

VLW—Light Metals and Their Application in Mining. (Die VLW—Leichtmetalle und ihre Verwendung im Bergbau.) E. Siegmund. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 4, Jan.-Feb. 1932, pages 33-38.

A few examples of the use of Duralumin, Elektron, Lautal and Silumin in coal cutters, drilling machines, oxygen containers, tipples, etc. are illustrated. Savings in weight amounting to more than 50% as against steel are described in detail. Ha (9)

Aluminum in Electro-Magnetic Constructions. (L'Aluminium dans les Constructions Électromagnétiques.) P. Saurel. *Revue de L'Aluminium*, Vol. 9, Jan.-Feb. 1932, pages 1638-1642.

For very large coils the author advises the use of Al windings but these should be insulated and tightly wound; oxide insulation often causes failures. Several examples of magnetic separators, brakes, etc. are discussed. AH+Ha (9)

Construction of Bridges and Other Structures of the Deutsche Reichsbahn-Gesellschaft in 1931. (Der Brückenbau und der Ingenieurhochbau der Deutschen Reichsbahn-Gesellschaft im Jahre 1931.) Schaper. *Die Bautechnik*, Vol. 10, Jan. 1, 1932, pages 5-8; Jan. 15, 1932, pages 32-35; Feb. 5, 1932, pages 63-65.

Tests were made to determine the distribution of stresses on pillars and substructures of the bridge over the Sahle river, and to determine the coefficient of friction between the foundation and superstructures. Tests were also made on welds; static tests were made on welded seams. The corrosion-resistance of structural steels used was determined, and the effect of various protective coatings. Further investigations included the determination of the endurance strength of the steels as related to seaming and welding. Preliminary instructions on how to apply surface coatings for protection against rust on bridges are given. MAB (9)

Aluminum Foil Heat Insulation. T. A. Solberg & W. P. Sinclair. *Journal American Society of Naval Engineers*, Vol. 44, May 1932, pages 200-205; *Power*, Vol. 75, May 17, 1932, pages 717-718.

Al foil was first used as an insulator by spacing flat sheets of foil 0.0003" approximately ⅜" apart. Later it was found that good results could be obtained by slightly crumpling each layer and stacking or winding the sheets so that each sheet occupies a space of ⅜". The material is crumpled by hand just before installation. Embossed foil is used as it facilitates proper crumpling. The insulating effect of the foil is due to its high reflectivity and low emissivity. Foil 0.00045" thick is used for crumpling. A roll of foil 7" in outside diameter wound on a 1" diameter tube carries a length of 3700 ft. and weighs only 12 lb. Based on a width of 12" this makes 3700 ft.² which when crumpled rolls up into 800 board ft. of insulating space. The material is easily installed. On pipes or other surfaces where the insulation is exposed it must be protected by a heavier sheet of Al or galvanized Fe. Crumpled foil insulation has been used extensively abroad. It was found that the foil lost only about 1% of its initial reflectivity on exposure to the atmosphere. The standard salt-spray test spotted the foil in about 40 hr., and after 200 hr. small holes were present. This is an excessively severe test, and indicates that foil has considerable resistance to corrosion. Foil insulation has the advantage of (1) very low weight, (2) cleanliness, (3) resistance to distintegration and "lumping" from vibration, (4) imperviousness to water and moisture, (5) low weight and space requirement of uninstalled foil, (6) low specific heat, (7) ease of manufacture, and (8) fire resistance. It can be used at temperatures from 0 to 1000° F. A small amount of microscopic tarnish has little effect on heat insulating properties. JLG+AHE (9)

A General Study on the Strength of Materials to be Used in Boiler Construction—Investigation on Causes of Failures in Superheater Tubes (Une étude d'ensemble sur la résistance des matériaux à employer dans la construction des chaudières—Recherche des causes d'accident des tubes de surchauffeurs). G. Paris. *Chaleur et Industrie*, Vol. 13, Jan. 1932, pages 3-11.

It is possible by means of examination of inner and outer surfaces of the tubes and examination of fractures and metallographic structure of the steel to determine the causes of tube breakage. On the inside, oxidation and decarburization can be observed as well as oxidation on the outside, these resulting from action of steam and vapor at high temperatures. The critical points being in the neighborhood of the service temperature, there is a greater danger of annealing and overheating in superheater tubes than in boiler tubes. While for boiler tubes a mild steel with 0.15% C is satisfactory, for superheater tubes a metal with better resistance to heat and steam is required. The use of special alloy tubes of high price does not seem to be a considerable advance over that of C steel tubes produced by specialized manufacturers. 20 photographs and micrographs. FR (9)

Acid Resisting Metal Used for Picklers Racks. D. E. Stamm & J. C. Weaver. *Metal Progress*, Vol. 21, Mar. 1932, pages 61-64.

Pickling baskets of cast bronze, Monel, "Duraloy" (high chrome iron), "Durimet" (Cr-Ni-Si alloy), "Nichrome" and "Hastelloy" are proving more economical and safer than the archaic wooden baskets. Nichrome and Hastelloy (Fe-Ni-Mo) are especially recommended for HCl. WLC (9)

American and Foreign Automotive Steel. T. H. Wickenden. *Metal Progress*, Vol. 21, Mar. 1932, pages 57-60.

A statistical study of steels now in use in the automotive industry for the manufacture of heavy duty units. It is pointed out that the tensile strength of gear steel is less important than its capacity to resist surface wear, and that pitting on a gear is due to repeated stressing above its endurance limit in compression. Therefore case hardened gears are recommended. The tendency among foreign manufacturers is towards an increased use of alloy steels. One practice peculiar to the foreign industry is the use of an air hardening gear steel of analysis, C 0.30%, Ni 3.5%, Cr 1.50-1.75% and Mo 0.15-0.25%. A table of the British Engineering Standards Association Specifications is included. WLC(9)

Non-Ferrous Metals in the Automotive Industry. Francis A. Westbrook. *Metal Industry*, N. Y., Vol. 30, Apr. 1932, pages 145-146.

A brief survey of the diverse uses to which Al, Cu, Ni, Pb, etc., are put and the quantities involved is given. PRK (9)

Many Metals Used in Navy Dirigible Akron. *Iron Age,* Vol. 128, Nov. 5, 1931, pages 1173, 1221.

While Al and its alloys predominated in the construction of the airship, several ferrous alloys and other metals were used. The outstanding requisites in the selection of metals were strength and lightness. Alloy steels in Ni, Cr-Mo and other grades were used. Ni steel is used for outrigger fittings. Exhaust manifolds are of stainless steel. Non-magnetic alloy steel is used around the control board. Various fittings are of plain C steel. Gas and oil tanks and heating and ventilating pipes are of Al. Weight of electrical equipment is kept to a minimum by the use of Al and its alloys. VSP (9)

Ancient Volumes in Vatican Protected by Steel Shelving and Air Conditioning. *Iron Age,* Vol. 128, Sept. 3, 1931, pages 632-634.

Description of the installation by Snead & Co. of pressed steel shelves and cast iron supporting members. The air conditioning installed is the "zigzag" system developed in America. VSP (9)

Cable Reels a Growing Outlet for Steel. *Iron Age,* Vol. 128, Nov. 19, 1931, pages 1294-1296.

The advantages of steel reels are: they cannot rot; no renailing damage; rough edges cannot develop with hard usage; repair cost is low; they are exceptionally strong as to torsion, impact and crushing strains. Drums and heads are made of sheet steel in gages from No. 16 to No. 10. They are assembled by electric arc welding. VSP (9)

New Constructions of Cylinder Covers of Oil Engines. (Neue Bauarten von Zylinderdeckeln für Oelmaschinen.) E. Kleinschmidt. *A E G-Mitteilungen,* Jan. 1931, pages 7-10.

For cylinder covers which are subjected to particularly severe mechanical and thermal stresses, cast-iron has been used but this is never as reliable as steel. A new method is described by which the covers are soldered or brazed together in parts of a very high-grade steel. Ha (9)

Modern Metals for Decorating a Modern Playhouse. George Kester. *Metal Progress,* Vol. 21, May 1932, pages 25-29.

An architect discusses the application of metals in securing various decorative and architectural effects. WLC (9)

Aluminum Alloys in Transportation. A. Holyhauer. *Metal Progress,* Vol. 21, Mar. 1932, pages 37-41.

A summary of recent applications of Al base alloys in the construction of motors, aircraft, truck bodies, and railroad rolling stock. A new alloy containing Cu, Si, Ni, and Mg has a coefficient of expansion of .0000105/°F. between 70° and 212°F. This lower expansion makes the metal useful for casting pistons of low clearance. Low centrifugal force on crankshafts is attained by making connecting rod of light Al alloy (4% Cu, .75% Si, and .75 Mn) having a tensile strength of 60,000 lb./in.^{2} The increased cost of manufacturing truck bodies and freight cars of Al is offset many times by saving in dead weight. Tank cars for transportation of corrosive chemicals are constructed of corrosion resisting Al alloys. WLC (9)

Large Steel Saddle Castings. *Iron & Coal Trades Review,* Vol. 124, Feb. 12, 1932, pages 278-279.

Description of the molding and casting of the saddles for carrying the ropes of the new Hudson River Bridge. The saddles weigh 150 tons each. Ha (9)

Forming, Annealing and Polishing of Utensils of 18-8. *Metal Progress,* Vol. 21, Apr. 1932, pages 44-47.

Description of equipment and operations in the drawing of 18-8 by foremen of Lalance and Grasjean Co., Woodhaven, N. Y. The presses necessary for this material must be 3 times as powerful as those used for ordinary work in Fe or Cu. Lubrication and die clearances are similar but more annealing operations are required to prevent cracking of 18-8. 5 minutes at 1950°F. followed by air cooling is satisfactory to remove the stresses; pickling is done hot in 10% HCl followed by a dip in warm 10% HNO_3. Finishing consists of grinding with muslin wheels loaded with 60, 120, and 200 mesh grit at 2200 to 2500 r.p.m. and final buffing with tripoli and green rouge. WLC (9)

Use of High Quality Cast Iron in Constructing Machines. (Verwendung von hochwertigem Gusseisen im Maschinenbau.) *Maschinenkonstrukteur-Betriebstechnik,* Vol. 65, Mar. 5, 1932, pages 29-30.

C exists in cast Fe in the form of graphite or carbide. With the latter, when making hard tool steels, a lower Si content is used. The C content is usually held between 0.5-0.8% for machine parts, so that the amount of pearlite is greater. The bath should be carefully watched, since inclusions will form, resulting in fracture. Tensile strength can be increased with certain compositions of cast Fe by heat-treating. The varied effects of additions of Si, Al and Ni (to form graphite) and of Mn, P, Cr, S, and Mo (to form carbide) are discussed. Cr is specially advocated for hardness. MAB (9)

Use of Triple Lead Jacket Cable in Unsafe Mining Districts. (Verwendung von Dreibleimantelkabeln in Bergschädengebieten.) G. Kopplin. *Glückauf,* Vol. 68, Apr. 16, 1932, pages 373-374.

A Pb-covered jacket surrounds each Cu wire in an A.C. 3-wire mine transmission line instead of 1 Pb-covered jacket for all 3 wires, as in the common type of belt or expansion cable. This new type of cable was installed at the Hoesch-Köln Neussen A.G. Mines and physical tests were made at the Köln-Riehl Wire & Cable Works. Comparison data against single Pb jacket show an approximate 10% increase in cost, together with 4 to 15% greater life and endurance. In addition, this new cable is guaranteed to stand 5% expansion as against 1.5 to 2.0% for so-called expansion cable. In dangerous mine areas the use of triple Pb jacket cable is far superior to the old type and will prove a real economy. DTR (9)

Smoothness of Nitrided Surfaces. *Correspondence from* G. Kuwada. *Metal Progress,* Vol. 21, Apr. 1932, pages 71-72.

Nitrided spinning rings for textile machinery are proving more resistant to abrasion and corrosion than polished parts of carburized steel. WLC (9)

Why Steel Mine Cars. Donald D. Long. *Coal Age,* Vol. 37, May 1932, page 199.

Advantages of steel mine cars are discussed. CBJ (9)

HEAT TREATMENT (10)

Case Hardening & Nitrogen Hardening (10c)

Gas Carburizing Processes Receive Wide Approval. *Steel,* Vol. 90, Jan. 4, 1932, pages 162-163.

The continuous gas carburizing process is the outstanding development in heat treating practice for 1931. This process makes use of a continuous furnace and an atmosphere of flue gas (for its CO_2 content) mixed with a hydrocarbon such as methane, butane, propane or natural gas. The oil carburizing process is another noteworthy development. This process utilizes a retort furnace in which drops of oil are continually introduced and vaporized to form a carburizing gas. JN (10c)

Nitrogenization of Some Special Steels by Ammonia. (Azotowanie pewnych stali specjalnych przez amoniak.) E. Steczko. *Prace Badawcze PWU,* No. 1, 1931, pages 7-50.

20 references. The investigations demonstrated that the steels containing Cr and Al are best suited to nitrogenization, the best temperature for the process being 500° C. These steels do not show any notable surface decarburization and when nitrided thus possess the superiority over others. The annealing even at as high temperature as 700° C. does not change the sorbitic structure of the nitrided sample. On the contrary other steels, and the plain carbon steels specially, show a distinct decarburization and deterioration of the surface during nitriding. ZJ (10c)

Surface Hardening with the Oxy-Acetylene Torch. (Die Oberflächenhärtung mit der Acetylen-Sauerstofflamme.) *Zeitschrift für Schweisstechnik,* Vol. 21, Dec. 1931, pages 293-294.

The new method of the Deutsche Edelstahlwerke, Krefeld, designated as "Doppel Duro Verfahren" is intended to harden the surface of crank shafts. A flattened out oxy-acetylene torch heats up the revolving shaft, the heated zone being immediately quenched by water of 40-50° C. The depth of the hardened case depends on the revolution speed (0.15 — 0.2 m. per min.) and amounts to 2-6 mm. No warping occurs. This thermal surface hardening method costs only 1/3 of the carburizing case hardening process. EF (10c)

Surface Condition, Structure and Tensile Properties of Case Carburizing Steels in Relation to the Heat Treatment. (Oberflächenbeschaffenheit Gefügeausbildung und Festigkeitseigenschaften von Einsatzstählen in ihrer Abhängigkeit von der Wärmebehandlung.) H. Müller. *Zeitschrift des Bayerischen Revisionsvereins,* Vol. 36, Mar. 15, 1932, pages 45-47; Mar. 31, 1932, pages 61-65; Apr. 15, 1932, pages 78-79.

The experiments were carried out on one straight carbon case carburizing steel and a Cr-Ni case carburizing steel. Suitable heat treatment methods were devised for these steels in order to eliminate the formation of a cementite network. The results are as follows: The fracture, the structure, and also the tensile properties of the case hardened steels show that upon case carburizing the steel should be cooled as rapidly as possible in order to attain a fine grain in the core and for eliminating a network of cementite. The cooling velocity necessary to just avoid the formation of the cementite network depends on the type of steel and the dimensions of the case carburized piece. Higher cooling velocities are to be avoided due to the setting up of internal stresses. A difference of structure of the transitory zone between case and core of samples slowly or more rapidly cooled after case carburizing could not be observed. Subsequent annealing at 650° C. does not affect the grain size but the cementite, provided the cementite crystals are not too coarse. Coarse cementite can be avoided only by rapidly cooling after case carburizing. Annealing at 900° C. brings about a fine grain of the core. The structure of the case of samples annealed at 900° C. depends more on the cooling velocity in that slow cooling improves the structure but rapid cooling somewhat impairs the structure. If the service conditions of the piece are not such that a fine grain in the core is necessary, annealing at 650° C. is sufficient. The following procedure is given: (1) for steels to meet normal requirements: case carburizing, cooling (with a velocity according to the dimensions) annealing at 650° C., hardening of the case. (2) for steels to meet highest requirements: case carburizing, cooling, hardening of the core with a velocity which just suppresses the cementite net work, annealing at 650° C., hardening of the case. 8 references. GN (10c)

Aging (10f)

Influence of Cold Rolling Upon the Hardening of Duralumin. (Einfluss der Kaltverdichtung auf die Aushärtung von Duralumin.) K. L. Meissner. *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, pages 88-89.

The effect of cold-rolling following the quenching upon the subsequent hardening at room temperature of duralumin was studied. It was found that cold-rolling interferes with the subsequent hardening, and that this interference is the greater the greater the amount of cold-rolling. If, however, the cold-rolling does not immediately follow the quenching, but follows 4-6 hours after quenching, the hardening process is not disturbed. RFM (10f)

Malleableizing (10g)

High Quality Malleable Casting. (Ueber hochwertigen Temperguss.) E. Piwowarsky. *Mitteilungen aus dem Giesserei-Institut der technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 6 pages.

See *Metals & Alloys,* Vol. 2, Nov. 1931, page 265. (10g)

Annealing Furnaces for Malleable Iron. (Fours à recuire la Malléable.) Chr. Kluijtmans. *Revue de Fonderie Moderne,* Vol. 26, Mar. 10, 1932, pages 75-78.

The conditions in the annealing of malleable iron are investigated for different types of containers and different kinds of furnaces and fuels; the average costs for a great number of installations in France are tabulated. As these investigations, however, comprise quite a few obsolete furnaces the author recommends their replacement by new ones for obtaining real economies. Ha (10g)

JOINING OF METALS & ALLOYS (11)

Gas Welded and Brazed Joints for High Nickel Alloys. F. G. Flocke, J. G. Schoener & R. J. McKay. *Journal American Welding Society,* Vol. 11, Mar. 1932, pages 12-16.

Paper read before the 32nd annual convention of the International Acetylene Association, Chicago, Nov. 1931. See *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 249. TEJ (11)

Tests of Joints in Wide Plates. W. M. Wilson, J. Mather & C. O. Harris in coöperation with Chicago Bridge and Iron Works. *Engineering Experiment Station, University of Illinois Bulletin,* No. 239, Vol. 29, 1931, 71 pages. Price 40 cents.

Full size tensile tests, made in a 3 million lb. testing machine, on wide plates, up to 64", indicated that such plates will give about 90% of the unit strength as determined on specimens 1½" wide. Welded butt joints in 64" plate showed as great strength as the continuous plates. The effects of different types of riveted joints, rivet spacing, the shear strength of rivets, bending in lap joints, and effects of different methods of welding lap joints are discussed. Coated electrodes developing an inert gas in melting, produced better results than those that did not contain such a gas forming coating. HWG (11)

Brazing (11a)

The Engineering Silver Solders. Ernest A. Smith. *Engineering,* Vol. 133, Apr. 15, 1932, pages 449-451.

The increased use of Ag solders for engineering purposes has led to research work on their mechanical and physical properties. The work of various investigators is summarized. The Ag content of these alloys varies from 9-10% in the lower grades to 30-70% in the medium and higher grades. The latter are Ag-Cu alloys to which Zn from small quantities up to about 20% is added to lower the melting point. The lower grades are ordinary brazing brasses containing a small quantity of Ag. The relative fusibility of Ag solders varies from 670 to 850° C. Tables are included giving melting points, mechanical properties, electrical conductivities of Ag-Cu-Zn alloys as well as British, U. S. and German specifications. The need for further research on these alloys is stressed. LFM (11a)

Distillation Phenomena During Hard-Soldering of Copper-Zinc Alloys. (Destillationserscheinungen beim Hartlöten mit Zink-Kupferlegierungen.) W. Claus. *Zeitschrift für Metallkunde,* Vol. 23, Aug. 1931, pages 243-244.

The application of diffusion equations to soldering is examined critically and limitations shown. Vaporization of one of the solder constituents invalidates such application, as in brazing Fe with Cu-Zn hard solder. RFM (11a)

Soldering (11b)

Grained Aluminum Solder (Gekörntes Aluminium-Schlaglot). L. Rostosky. *Aluminium Hauszeitschrift V.A.W. und Erftwerk,* Vol. 4, Mar. 1932, pages 73-74.

A new hard-solder for Al is described which has a melting point 120° C. lower than Al; it is made in 3 different grain sizes. Joints can be made with it which are said to be practically just as solid, corrosion resisting and of the same color as welded joints, they can be made with the ordinary Bunsen burner. Examples are given. Ha (11b)

Brazing Metals with Silver Solders. A. Eyles. *Mechanical World,* Vol. 91, Jan. 1, 1932, page 5; *Machinery,* Vol. 38, Jan. 1932, pages 348-350.

See *Metals & Alloys,* Vol. 3, May 1932, page MA 134. RHP (11b)

Soldering and Modeling of Aluminum. (Löten und Modellieren von Aluminium.) *Deutsche Motorzeitschrift,* Vol. 8. Dec. 1931, pages 420-422.

Calls attention to the present status of soldering broken Al parts. The application of the Tialit solder compound (not commercially available) is discussed and its possibility is illustrated by two motor blocks and a ventilator in the damaged state and after repair work. EF (11b)

Welding & Cutting (11c)

Welding as Used in Installing Pipes. (Rohrinstallation mit Schweissung.) *Gas- und Wasserfach,* Vol. 75, Feb. 20, 1932, pages 148-150.

With the knowledge of the value of fusion welded pipe joints increasing steadily, it becomes necessary to compare it with other kinds of welds and seams for adaptability and efficiency. Emphasis is placed on welding technique, which includes knowledge of the various methods, materials and their applicability. MAB (11c)

Electric Welding in Boiler Construction. (Elektroschweissung im Dampfkesselbau.) *Elektroschweissung,* Vol. 3, Mar. 1932, page 53.

The paper reports the experiences in welding man-holes of boilers. GN (11c)

Fusion Welding of Copper. (Sur la Soudure Autogene du Cuivre.) *Cuivre et Laiton,* Vol. 5, Mar. 30, 1932, pages 129-136; Apr. 15, 1932, pages 149-157.

The possibility of fusion welding of Cu with particular reference to its application in Cu parts of locomotives (fire boxes, water tubes, boiler, etc.) and based on experiences made by the German and Swiss state railways are discussed. A main difficulty was to get a welding electrode which would not melt before the piece itself; this happened always because the electrode used was of electrolytically pure Cu while the piece contained oxides and therefore had a higher melting point. A Swiss patent employs an electrode composed of electrolytic Cu with an addition of Ag and P with a melting point of 900° C.; it flows easily and covers the piece like solder. This same material can equally well be applied with the oxy-acetylene process. The procedures and the equipment for it are fully described, photomicrographs of the welds showing the uniform structure are given and a number of applications and preparation of pieces to be welded are illustrated. Ha (11c)

The Electric Welding of Battered Rail Ends. *Engineering,* Vol. 132, Oct. 2, 1931, page 452.

Short article describing experimental electric welding being done by the Canadian Pacific Railway. Rails rebuilt by this process were found to be in good condition after 16 months' service. When first completed the welds show a scleroscope hardness of 55 and after a few months service the hardness increases to 60-63. LFM (11c)

Welding in All-Steel Body Production. Joseph W. Meadowcroft & James J. Paugh (Edward G. Budd Mfg. Co.). *S.A.E. Journal,* Vol. 30, Mar. 1932, pages 143-149.

All-steel welded bodies for passenger cars have many advantages over composite bodies, among them being fewer parts, doors of only 2 pieces, no visible outside seams, lower tops for the same head room, less roof weight, lower center of gravity, greater safety, increased visibility, permanent quiet, economical upkeep and perfect outside lines. Wood and steel react so differently to stress that neither adds much to the strength of the other in a composite structure. Steel alone, welded into a unit structure, is lighter and less bulky. The entire side of the body is stamped from a single sheet, with the openings die formed to reenforce it. Chassis frame and body follow the same lines, so that they reenforce each other and body sills can be omitted. This plan saves 2" in height, as compared with other bodies. Flash welding is employed to join sheets 120" long and of any desired width, because mills are not equipped to produce, economically and speedily, sheets of the required accuracy. The tonneau rear seams are flash welded also, and the cowl and roof are attached by spot welding. Flash welding of the larger sheets requires uncommonly accurate alignment of the edges of the metal due to the scarfing operation which trims both sides of the weld in one operation. Magnetic clamping allows perfect alignment since the pressure is self-contained. Handling the large units for welding small reenforcements like those for hinges, locks and fender bolts can only be accomplished on a spot-welding machine of great flexibility, used in conjunction with overhead carrying equipment. Electrodes are important; most of them are of hard-drawn Cu or a material that contains a large percentage of Cu. To secure long life, electrodes are cooled to within ⅛" of their points wherever possible. The automobile body must have a certain capacity, must be strong and serviceable, must possess certain conveniences and must meet the requirements of appearance. In the all-steel body, the necessary skin or shell is utilized as the chief structural member and reenforced by additional strengthening members wherever needed. In a sedan are found 2303 spot welds and 140" of flash welding, plus the welding of the open sheets. Various applications of welding and the different methods are covered in the discussion, special emphasis being laid on the ductility of the metal in the weld. The welding of thin sheet metal is also considered. Relative tensile strengths of the weld and the parent metal are mentioned, as well as the point at which a weld ruptures. In this connection one member suggests testing the parent metal before welding and comparing the results with those obtained from the welded piece to show the effect of welding upon the metal. WAT (11c)

Basic Principles of Education and Training in Industry as They May be Applied to Welding Instruction in Trade and Vocational Schools. W. H. Magee. *Paper read before the 32nd Annual Convention, International Acetylene Association,* Chicago, Nov. 1931, 7 pages.

General requirements for teachers and curriculums. Ha (11c)

Discussion of Paper on "Resistance of Metal Fabric" by W. T. Ober. *Journal American Welding Society,* Vol. 10, Dec. 1931, pages 14-15.

Discussion of Paper presented at the Fall meeting of the American Welding Society in Boston, Sept. 1931. Paper published in *Journal American Welding Society,* Vol. 10, Sept. 1931, pages 50-52. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 43. TEJ (11c)

Discussion of Paper on "Welding Solves Another Problem" by Frank P. McKibben. *Journal American Welding Society,* Vol. 10, Dec. 1931, pages 5-8.

Discussion of Paper presented at Fall Meeting of the American Welding Society at Boston, Sept. 1931. Paper published in *Journal American Welding Society,* Vol. 10, Sept. 1931, pages 47-49. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 71. TEJ (11c)

All Welded Turbine Cases Built Up From Plate. A. M. MacFarland. *Welding,* Vol. 3, Jan. 1932, pages 51-54.

Procedure used in construction of an arc welded turbine case. 2,000 lbs. of heavily fluxed electrode was used. (11c)

Recent Investigations of the Gas Fusion Welding of Copper. (Neuere Untersuchungen über die gasschmelzschweissung des Kupfers.) K. Altmannsberger. *Oberflächentechnik,* Vol. 9, Feb. 2, 1932, pages 21-22.

The often observed extraordinary low strength of a Cu weld is explained by the softness of the material, which absorbs oxygen at higher temperatures. Due to its good heat conductivity a weld should have double-V-shape and should be made simultaneously from both sides with a larger burner than used for iron; the flame should be neutral and be applied to the metal vertically. After welding the seam should be hammered. Only acetylene, not hydrogen must be used, and the welding pencils should have a melting point lower than that of the Cu, i. e. 1085°C, and contain a deoxidation agent; they should be preferably of an alloyed type; suitable materials are: Be, Si, Ti, Mn, As, Sb. Fluxes must be acidic; a boric acid base with salts, for instance sodium phosphate or ferro-potassium cyanide. Ha (11c)

Welding Gas Mains in Australia. James Lyall. *Welding,* Vol. 3, Jan. 1932, pages 28-29.

The largest pipe line so far laid in Australia is an 18" diameter gas line, 12½ miles long. It was welded by the oxy-acetylene process. The author tells how a branch pipe was welded to an 8" main without cutting off the gas supply. TEJ (11c)

Practical Application of the A.S.M.E. Welding Code. A. J. Moses. *Journal American Welding Society,* Vol. 11, Feb. 1932, pages 13-15.

Paper presented at the joint meeting of the Metropolitan Section of the A.S.M.E. and A.W.S., Jan. 5, 1932. In a large measure the interest aroused by pressure vessel welding has been directly responsible for the remarkable progress made in the art during the past decade. The problem of ideal welding lies in the securement of a joint or weld metal of the same physical and chemical properties as the base material. The author discusses the advantages of welding, the variables entering into the process and the control of variables. Test data give physical properties of welds. TEJ (11c)

Discussion of Paper on "An Improved Product by the Use of Bronze Welding" by H. F. Reinhard. *Journal American Welding Society,* Vol. 10, Dec. 1931, pages 22-23.

Discussion of Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in Journal of the American Welding Society, Vol. 10, Oct. 1931, pages 5-8. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 42. TEJ (11c)

Shrinking the Scrap Heap with Electric Welding. G. N. Robinson. *Welding,* Vol. 3, Jan. 1932, pages 26-27.

The author cites many examples of how maintenance cost reduction and low stock inventory are made possible by arc welding. TEJ (11c)

Coated Electrodes. G. Raymond. *Welding,* Vol. 2, Dec. 1931, pages 789-792.

The author compares properties of open arc and shielded arc welds. Test specimens are illustrated. The shielded arc principle is explained. Part of the A.S.M.E. Pressure Vessel Welding Code is included with comments by the author. TEJ (11c)

Testing of Welding Torches for Low Pressure Acetylene. (Das Prüfen von Schweissbrennern für Niederdruck-Azetylen.) K. Poettgen. *Autogene Metallbearbeitung,* Vol. 25, Feb. 1, 1932, pages 33-36; discussion with W. Knoch, pages 36-38.

A method for testing acetylene burners proposed by Knoch is discussed and the behavior of a burner was tested as dependent on temperature and pressure in the acetylene chamber. The longer the flame burns without interruption, the more satisfactory the operation. Ha (11c)

A Revolution in Joints. G. Raymond. *Welding,* Vol. 3, Mar. 1932, pages 163-165, 187.

Presented before The Engineers Club, Oklahoma City, Okla. An engineer paints a striking picture of what the welding processes are doing to promote production in all industries. TEJ (11c)

Resistance Welding Budd Bodies. D. J. Rahn. *Welding,* Vol. 2, Dec. 1931, pages 802-803, 807.

A description of some of the difficult spot welding applications at the Budd Manufacturing Plant. Cleverly designed electrodes are used to reach out-of-the-way places. TEJ (11c)

Arc-Welding in Shipbuilding Construction. J. H. Patterson. *Welder,* Vol. 3, Jan. 1932, pages 2-5.

The reasons for the wide use of the electric arc in welding ship structures are reviewed and the great influence of proper design and reliable workmanship for saving in weight and time is pointed out. Ha (11c)

Discussion of Paper on "Welding of Copper and Brass Piping" by H. V. Inskeep. *Journal American Welding Society,* Vol. 10, Dec. 1931, pages 28-29.

Discussion of Paper presented at Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in *Journal American Welding Society,* Vol. 10, Oct. 1931, pages 21-24. See *Metals & Alloys,* Vol. 3, Apr. 1932, page MA 100. TEJ (11c)

The Welding of Steel Structures in Germany. Werner Boos. *Journal American Welding Society,* Vol. 11, Feb. 1932, pages 20-23.

The large number of steel structures which have been welded in Germany during the past year, e.g., railway and street bridges, shops, station halls, office buildings, cranes, etc.—give evidence of the theoretical, practical and psychological development in this sphere. The author describes some of the up-to-date welded structures in Germany. Both oxyacetylene and electric arc welding are employed, the choice depending on which is the most economical in each individual case. Welding technique and special structural steel shapes are also discussed. TEJ (11c)

Cutting Down and Re-erecting Gas Welded Tanks Economically. Marvin K. Allen. *Welding,* Vol. 3, Mar. 1932, pages 158-160.

A recent experience of cutting down by means of an oxy-acetylene torch and re-erecting an all-welded oil storage tank of 10,000 bbl. capacity demonstrated that this type of construction has a salvage value of 42% as compared to less than 10% for a riveted tank. The author tells how the job was done. TEJ (11c)

Progress in Welding in First Half of 1931. (Fortschritte in der Schweisstechnik im ersten Halbjahr 1931.) W. Lohmann & E. H. Schulz. *Stahl und Eisen,* Vol. 52, Mar. 3, 1932, pages 220-223.

Bibliographical summary of welding progress during 1st half 1931. Includes 35 references and is arranged according to following heads: (1) Effect of materials. (2) Welding methods. (3) Testing methods. (4) Properties of weld. (5) Behavior of weld in operation. (6) Constructive problems. (7) Economical problems. DTR (11c)

Method of Joining Oil Well Casing Improved by Welding. J. F. Lincoln. *Welding,* Vol. 3, May 1932, pages 305-306.

By using a welded bell and spigot joint instead of the conventional screw joint for oil well casings, the casings are easier to handle and run, the joints are stronger and more resistant to corrosion and are tighter. The author describes the procedure used in making these joints. TEJ (11c)

Effects of Machine Gas-Cutting on the Metal Cut. *Machinery,* Vol. 38, Dec. 1931, page 264.

Abstract of a paper by L. M. Curtiss entitled "Some Methods and Effects of Machine Gas Cutting." See *Metals & Alloys,* Vol. 3, July 1932, page MA 216. Ha (11c)

New Process Called Shot Welding. *Industry & Welding,* Vol. 3, Apr. 1932, page 19.

In welding stainless steel sheets a separation of the Cr at the weld points gave rise to corrosion in these spots. This was eliminated by developing a spot welding process (Edw. G. Budd Mfg. Co.) at extremely high temperature which speeded the process up to a point that the weld was made before Cr separation took place. Amperages up to 1200 are used and a time switch is set so that the current is applied from 0.01 to 0.001 sec., a time so short that metallurgical changes have no time to take place. Ha (11c)

Structural Steel Welding Report. *Journal American Welding Society,* Vol. 10, Dec. 1931, pages 38-50; Discussion, Vol. 11, Jan. 1932, pages 5-8.

This portion of the report consists of Sections 6, 7, 8 and 9 which include Miscellanea, Conclusions, Recommendations and Fields for Further Research. Important conclusions are: (1) No harmful effect on the base metal due to the welding was disclosed. (2) In this range of tests, no important difference was found in strength of welds made by any of the fusion welding processes employed—the electric arc (direct and alternating) and oxy-acetylene. (3) Specimens from a given shop tested in different laboratories gave consistent results. (4) Qualification tests of welders were reflected in their subsequent program performances. (5) Symmetrical joints of the end welded, side welded and combined types were approximately 35%, 10% and 14% stronger, respectively, than similar non-symmetrical joints. (6) Although side welds showed greater uniformity, end welds had 35% greater average strength. (7) Unit strength of a perfect small weld is somewhat greater than that of a larger one, but the variation is not sufficient to warrant the use of different working stresses. (8) Use of square butt joints should be restricted to sizes below ⅜" and the use of single V joints to sizes below ¾". (9) Unit strengths of continuous and intermittent welds were substantially equal. (10) The strengths of butt welds made in the flat and vertical positions were approximately equal. (11) For fillet welded joints, wherein bending was negligible, the average shearing strength was 42.5 kips/in.^{2} of throat. The strength of joints in which considerable eccentricity was present averaged from 22 to 44 kips/in.^{2} of throat. (12) The average strength of all butt welded specimens was 49.6 kips/in.^{2} of weld throat. (13) Average ratio of yield point to tensile strength of base metal is 60.6%, whereas average ratio for welded joints is 72.7%. (14) Minimum length of fillet welds recommended is 4 times the fillet size. (15) Qualified welders may be expected in commercial practice to produce weld strengths within 12% of a general average. Important recommendations are: (1) Recommended qualification tests for welders are outlined. (2) Permissible working stresses as recommended by the American Welding Society are endorsed—shear 11.3 kips/in.^{2} of weld throat; tension 13.0; compression 15.0. (3) Cross-section of welds should be measured by gages. TEJ (11c)

Welding Electrodes for Steel Constructions. (Beurteilung von Elektroden für Stahlbauten.) E. Klosse. *Elektroschweissung,* Vol. 3, Feb. 1932, pages 28-30.

Tells how the qualification of welding electrodes can be determined numerically with special consideration of its economies. GN (11c)

Welding of Extruded Bronze. Ira T. Hook. *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 42-46; *Welding,* Vol. 3, June 1932, pages 356-360; *Industry & Welding,* Vol. 3, May 1932, pages 3-7, 30; June 1932, pages 17-20.

A discussion of the metal extrusion process as applied to Cu-base alloys, compositions of these alloys, their welding properties and welding procedure. Oxy-acetylene welding is most commonly employed. TEJ + Ha + JN (11c)

Ductility in Arc Welds with Some Reference to Strength Values. Chas. H. Jennings. *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 37-42; discussion. May 1932, pages 24-25.

Paper presented at the annual meeting of the American Welding Society, New York, Apr. 1932. The author discusses the various methods of determining weld ductility and gives physical properties of several types of welds. The most satisfactory method of determining ductility properties of weld metal is by elongation and reduction of area values as obtained in the usual manner from standard ½" diameter A.S.T.M. tensile specimens. The ductility of butt welds may be obtained either from tensile tests with proper design of specimen, or the free bend test. TEJ (11c)

Holding Down Costs in Production Arc Welding. R. Kraus. *American Machinist,* Vol. 76, Jan. 28, 1932, pages 137-141.

Preliminary cutting should be accurate both to save weld metal and for a better joint. A little rust or mill scale is not harmful. Many coats of paint should be burned off with a torch. In shop welding, material ¼" thick and up to a 3/16" electrode may be used. Describes methods of forming the joints, allowance for contraction stresses, and how to overcome "blow." RHP (11c)

Arc Welding as a Maintenance Tool. H. F. Kneen. *Industry & Welding,* Vol. 3, Apr. 1932, pages 2-6.

The advantages of arc welding in maintenance and repair departments are pointed out and illustrated. Ha (11c)

The Novel Multiple Flame Torch System. A Fifty Percent Increase in Welding Speed. (Der neue Mehrflammenbrenner Keel. Eine neue 50% ige Erhöhung der Schweissgeschwindigkeit.) C. F. Keel. *Zeitschrift für Schweisstechnik,* Vol. 21, Feb. 1931, pages 26-38.

A multiple-flame torch is introduced including 1-3 individual flames for pre-heating of the welded material, for the welding operation itself and the eventual pre-heating of the welding rod respectively. The advantages claimed are: increase of welding speed, higher welding temperatures, and welding seams of smaller dimensions. The limit of the single torch is 100 liters acetylene per mm. sheet, while 130-160 liters C_2H_2 can be fed into the multiple-flame torch. A double flame torch is recommended for 2-10 mm. sheets and a triple torch above 10 mm. Tests are reported, showing the great efficiency of the novel welding outfit which yielded a 50% increase of the welding speed. The gas consumption is not very much lower, but the warping of the sheets is less pronounced, and the welding seam is of superior quality. The novel welding equipment is particularly suited for lap-welded joints, upright sheets and built-up welding performances. Horizontal as well as vertical seams can be made. Paper is also given in French. EF (11c)

Electric Resistance Welding. (La Soudure Électrique par Résistance.) Ad. Kloppert. *Revue Universelle des Mines,* Series 8, Vol. 7, Feb. 15, 1932, pages 270-275.

The principle of the utilization of the heating effect of the electric current for joining metals is discussed and its practical methods described. The author deplores that this type of welding has not found the same consideration in research and scientific study as other welding processes. Ha (11c)

The Growing Importance of Tests—What they Mean to the Welder and to the Welding Industry. H. L. Whittemore, John J. Crowe, A. B. Kinzel & W. B. Miller. *Paper presented to the 32nd Annual Convention of the International Acetylene Association,* Chicago, Nov. 1931, 13 pages.

The need for testing welds is discussed—tests are the only way to guarantee good welding. They are grouped in three classes: 1. Design tests to determine the value of base metal, method of welding, or design of joint. The specimens should be fabricated by a qualified welder. These tests are usually carried to destruction, the structure being unusable after test. 2. Qualification test for welders. As the properties for manual welds depend greatly upon the care and skill of the welder, materials and equipment are used as in actual production and tests made at frequent intervals to determine the welder's ability to make safe welds. 3. Product tests to insure a satisfactory product; there are destructive and non-destructive tests. The various methods for ascertaining physical properties and soundness of the weld by this group are described. Ha (11c)

Making Electrically Welded Jigs in Russia. Walter Wells. *Machinery,* Vol. 38, Dec. 1931, pages 248-249.

Deals with jig design. RHP (11c)

The Determination of the Working Time in Arc-Welding. (Die Arbeitszeitermittlung beim Lichtbogenschweissen.) M. Zscheile. *Werkstattstechnik,* Vol. 25, Sept. 1, 1931, pages 414-416.

An analytical investigation based on the volume of the seam to be welded. Ha (11c)

Applications of Resistance Welding. L. B. Wilson. *Welding Journal,* Vol. 28, Nov. 1931, pages 339-340, 352.

Paper read before the members of the Northwestern Branch of the Institute of Welding Engineers, Oct. 13, 1931. Necessity of reducing production costs has been the chief factor in the rapid progress made in applications of resistance welding. First employed in welding of cycle and motor rims, this process is now used for welding not only mild steel, but also malleable cast Fe, high C steel, Cu, brass and most of the commercial alloys. Parts to be welded should have equal sections, be capable of being clamped and be able to withstand the upsetting pressure without distortion. Spot welding tips with W alloy inserts have about 5 times the life of Cu tips. TEJ (11c)

Estimated Oxy-Acetylene Pipe Welding Costs. John H. Zink. *Welding,* Vol. 3, Feb. 1932, pages 111-113.

Reprinted from Nov. issue of the Official Bulletin of the Heating and Piping Contractors National Association. The author offers cost figures obtained in his own welding practice as a guide in computing pipe welding costs. TEJ (11c)

Making 400 Welded Jigs per Month. J. R. Weaver (Westinghouse Elec. & Mfg. Co.). *Machinery,* Vol. 38, Oct. 1931, pages 108-109.

General discussion of jig construction by arc-welding. This method is faster and cheaper than using a pattern and casting. In many cases, the jig can be welded for the same time and cost as for the making of the pattern alone. RHP (11c)

Machine Tool Frames Produced by Welding. J. R. Weaver (Westinghouse Elec. & Mfg. Co.). *Machinery,* Vol. 38, Nov. 1931, pages 171-172.

General discussion. Welding seems quicker and cheaper unless a large number of pieces are to be made, in which case a pattern and the use of cast iron may be just as good. RHP (11c)

Importance of Standardization in the Welding Industry. C. G. Watson. *Welding,* Vol. 3, Jan. 1932, pages 30-34.

The author offers some helpful suggestions as to how standardization can be brought about in the welding industry. TEJ (11c)

Welding Monel Metal. W. E. Warner. *Canadian Machinery,* Vol. 42, Dec. 1931, page 39.

Monel metal can be successfully welded by either oxy-acetylene, metallic arc or spot welding, provided proper precautions are observed. The oxy-acetylene flame should be reducing. An alcoholic solution of boric acid may be used as a flux. Where metallic arc welding is adopted, it is necessary to make the work the negative pole and to use a flux coated electrode. Monel metal can be welded on most spot welding machines now in use. WAT (11c)

Recent Developments in the Welding of Overland Pipe Lines. H. E. Rockefeller. *Paper read before the 32nd Annual Convention, International Acetylene Association,* Chicago, Nov. 1931, 4 pages.

The recent developments of welding long pipe lines, 70% of which was done by oxy-acetylene, and possible uses for pipe lines for other materials than gas or oil are discussed. The methods of welding and the influence of good welders are reviewed. Ha (11c)

The Application of the Theory of the Electric Arc on Welding—The Importance of Burning Depth in Electric Welding. (Die Anwendung der Lichtbogentheorie auf die Schweissung-Die Bedeutung der Einbrandtiefe beim Lichtbogenschweissen.) E. Rosenberg, W. Fink & E. Schwarz. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, July 4, 1931, pages 881-884.

Controversial remarks are exchanged in which the influence of the characteristic of the welding machine and automatic or manual welding on the welded seam is discussed with reference to previous articles. Ha (11c)

From the Stationary to the Movable Equipment for Spot Welding. (Von der stationaren zu freibeweglichen Punktschweisseinrichtung.) K. Ruppin. *Schweizerische Technische Zeitschrift,* Vol. 29, Feb. 11, 1932, pages 80-82.

The electric resistance spot welding offers difficulties when the parts to be welded are bulky. By developing a new apparatus, a so-called double spot welding apparatus, these difficulties are eliminated. This method uses 2 electrodes which are put side by side but not opposite as in the former methods. This is an essential improvement, the method is easier to handle and also cheaper. The new method is illustrated by a few practical examples. GN (11c)

Modern Fusion Welding and Cutting Equipment and Materials. H. Reininger. *Engineering Progress,* Vol. 12, Dec. 1931, pages 276-282.

Reviews the more important new processes and equipment used in welding. Metallurgical aspects of the subject are dealt with very briefly. RHP (11c)

ECONOMIC (16)

Silver, Its Application to Our Present Problem. RÉNÉ LÉON. *Mining & Metallurgical Society of America, Bulletin* No. 223, Vol. 25, Jan. 1932, pages 6-12.

A political-economical discussion of the question how the present financial depression and confusion the world over can be alleviated and the return of normal times be hastened leads the author to advocate the coining of Ag of high Ag content under an agreement between all governments and a Ag production tax as principal means to restore equilibrium in money exchange. Ha (16)

Geology and Economics of Tin Mining in Cornwall, England. ERNEST R. LILLEY (New York University and John Simon Guggenheim Foundation Fellow). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 479, 17 pages.

Cornwall is a very old mining section, and really modern methods of mining and concentrating have never been applied. Abundant ore is still present. A critical review of the operation of the various properties. JLG (16)

The Economic Significance of Specifications from the Standpoint of a User of Steel. P. PARKE. *Proceedings American Society for Testing Materials*, Vol. 31, Pt. 2, 1931, pages 963-966.

Some Causes of Increased Sales in Welded Piping. A. L. BYFIELD. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 4 pages.

A discussion of the points which have contributed to greatly increase the use of entirely or partially welded piping. Ha (16)

Why Not an International Silver Conference? CHAS. A. MITKE. *Mining Congress Journal*, Vol. 17, Dec. 1931, pages 656-59.

Excellent discussion of this subject. The quickest and most effective remedy for the present disastrous fall in prices is offered through raising the price of Ag and its restoration to a place in the world's monetary system. The action of governments has produced the present results, and it is by governments that the situation must be remedied. A table of comparative importance of Ag and other commodities is given. DTR (16)

The Restoration of Silver. TASKER L. ODDIE. *Mining Congress Journal*, Vol. 17, Dec. 1931, pages 654-655, 659.

Restoration of value of Ag to the extent, at least that it enjoyed in days before World War, would afford a currency in which people can have confidence because of inherent intrinsic value and relief afforded the growing burden on Au. It requires no great study to restore the value of Ag to its pre-war status. The step is easily taken, if the will to take it exists. DTR(16)

Tin in 1930. CHARLES WHITE MERRILL. *Mineral Resources of the United States*, 1930, United States Bureau of Mines, Part 1, Jan. 15, 1932, pages 355 to 383.

Imports of Sn in 1930 exceeded $60,000,000 in value, and domestic mine production was worth only $10,500 (15 long tons). Of this 13.1 tons came from Alaska (34.5 tons in 1929) and the remainder from North Carolina and South Dakota. In 1930, 23,393 long tons of secondary Sn were recovered, a decline of 24% from 1929. This secondary Sn is 29% of the virgin Sn imported in 1930. Imports of 80,734 long tons (87,127 in 1929) were more than any previous year except 1929, but less in value than any year since 1922. Of this British Malaya was the source of 69%, the United Kingdom 15%, the Netherlands 9%, Hong Kong 6% (total 99%) and Australia, Netherland East Indies, Germany, China, Canada and Haiti the remainder. World production of Sn in 1930 (174,000 long tons) decreased 9% from 1929. AHE (16)

Using Point System to Compute Molding Piece Rates. W. J. MCNEILL. *Foundry*, Vol. 59, Nov. 1, 1931, pages 59, 73.

Abstract of a paper read before the American Foundrymen's Association in Chicago. See *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 76. VSP (16)

The Mineral Position of the British Empire. CHARLES CAMSELL (Deputy Minister of Mines, Canada). *Canadian Mining & Metallurgical Bulletin* No. 238, Feb. 1932, pages 15-29.

The British Empire has large surpluses of most minerals. Canada has surpluses in Cu, Pb, Ni, Zn, asbestos, gypsum, mica, pyrite and talc only. AHE (16)

Silver, Copper, Lead and Zinc in the Central States in 1930. J. P. DUNLOP & H. M. MEYER. *Mineral Resources of the United States*, 1930, *United States Bureau of Mines*, Part 1, Dec. 24, 1931, pages 209-242.

The total value of the mine production of Ag, Cu, Pb and Zn in Arkansas, Illinois, Kansas, Kentucky, Michigan, Missouri, Oklahoma and Wisconsin in 1930 was $68,313,236 ($42,666,007 less than in 1929). Ag production, chiefly as a by-product from other metals, was 179,827 oz. worth $69,234 (206,133 oz. and $109,869 in 1929). Cu output was 169,558,013 lb. valued at $22,042,542, largely from Michigan (186,404,458 lb. and $32,807,184 in 1929). Pb shipments decreased 13.3% in quantity to 237,533 short tons and 31.2% in value to $23,753,300. Zinc output of 233,835 short tons worth $22,448,160 decreased from 329,935 tons and $43,551,420 in 1929. 9 references. AHE (16)

Gold, Silver, and Lead in South Dakota in 1929. CHAS. W. HENDERSON. *Mineral Resources of the United States*, 1929, *United States Bureau of Mines*, Part 1, 1931, pages 265-270.

In 1929, S. D. produced Au, Ag and Pb worth $6,595,001, a decrease of less than ½% from 1928. Au output was 316,836.85 oz., $6,549,599 in value. Ag production was 85,182 oz. worth $45,402. 7 references. AHE (16)

The Development of Gold Mining in South African Union. (Die Bergwirtschaftliche Entwicklung des Goldbergbaus der Südafrikanschen Union.) R. KRAHMANN. *Zeitschrift für Berg-Hütten- und Salinenwesen*, Vol. 79, 1931, pages B139-166.

An historical account of the development of the industry. Statistical data show its growth from 1884-1929. The mineralogical and geological nature of the deposits, technical and human power, production of each mine and the possible future and the industry are discussed. JGT (16)

Special Research Equipment and How it is Used. *Iron Age*, Vol. 127, June 4, 1931, pages 1811-1815.

Describes special equipment used in studying the properties of metals and determining how they can be applied to best advantage by the American Rolling Mill Co. In the metallographic laboratory, the equipment consists of 2 large inverted metallographic microscopes for examination of metals at magnification of 50-3000 diameters; one inverted microscope with a magnification of from 50-1500 diameters; one micro tessar for photographing samples at low magnification and a binocular microscope with magnification range of from 10-85 diameters for examination of features. Amount of H, O and N existing as impurities in metal is determined by vacuum fusion apparatus. Of universal interest is the method of calibrating pyrometers. In the investigation of vitreous enameling of sheet metal, the equipment consists of dipping pans, smelting furnaces, raw material jars for grinding screens and pans. The magnetic testing laboratory contains a Fahy simplex permeameter and control equipment for measuring permeability and hysteresis loss of bar or sheet samples. VSP (17)

Modern Heat Treating in Truck Manufacture. FRED C. SMITH (International Harvester Co.). *Metal Progress,* Vol. 20, Dec. 1931, pages 45-52.
The author describes the modern heat treating plant of his firm consisting of gas and electrically heated furnaces with modern control equipment. The arrangement is designed to facilitate the passage of work efficiently through the department and provide for the comfort of the workmen. Facilities for recovery and mixing old and new carburizing compound with minimum of dirt and discomfort to workmen are described. WLC (17)

Radial Engines Produced in Modern Plant. H. R. SIMONDS. *Steel,* Vol. 88, Feb. 5, 1931, pages 43-46, 50.
A description of the airplane engine manufacturing plant of the Pratt and Whitney Aircraft Co. in East Hartford, Conn., with descriptions of some of the special procedures involved in the accurate machining and finishing of various engine parts. JN (17)

A New X-ray-Metallographic Laboratory. (Un nouveau Laboratoire de Radiometallographie.) J. J. TRILLAT. *Revue d'Aluminium,* Vol. 8, Mar.-Apr. 1931, pages 1357-1363.
Several examples are described to show the advantage of X-ray testing for metallurgical purposes; the equipment of laboratory is described which has been installed in Bourget by 3 French companies to investigate Al, Cu and steels. Ha (17)

Close Control Cuts Losses in Piston Ring Castings. FRANK G. STEINEBACH. *Foundry,* Vol. 59, Dec. 1, 1931, pages 40-44, 46.
Describes the plant of the Perfect Circle Co., located at New Castle, Ind. Foundry losses, in manufacturing gray iron castings, were less than 5% of the castings produced during the first 6 mos. of 1931. VSP (17)

Commercial Heat-Treating Plant Has 16 Furnaces. HARRY TURNER (Ohio Heat Treating Co.). *Iron Age,* Vol. 128, Nov. 12, 1931, pages 1238-1240.
Description of the plant of the Ohio Heat Treating Co., Dayton, Ohio. 8 oven-type furnaces are arranged in 2 rows, with monitor roof overhead for localizing and removing excess heat. Furnaces range from 12" x 24" x 9" high speed to 36" x 84" x 24" carburizing furnaces. A 24-hr. service is maintained. VSP (17)

Heat Treating Department of a Modern Manufacturing Plant. J. B. NEALEY. *Western Machinery World,* Vol. 22, Dec. 1931, pages 568-570.
Equipment and methods used at the Lincoln automobile factory exemplify the most modern engineering achievements in this field. The furnaces and temperature controllers are described and illustrated. WAT (17)

Nickel Silver in Rod and Wire. RICH. E. BROWN. *Wire & Wire Products,* Vol. 7, Feb. 1932, pages 41-43, 58-59, 61-63.
An outline of the history and the development of nickel-silver is given with a description of present day methods of rod and wire production at the plant of the Seymour Manufacture Co., Seymour, Conn. The article is amply illustrated. Ha (17)

Makes Marine Castings in Panama Canal Foundry. C. A. MCILVAINE. *Foundry,* Vol. 59, May 15, 1931, pages 91-92.
Description of the equipment of the Balboa shops at Balboa, C. Z. VSP (17)

The Metal Mine—Wire Rope Problems. A. J. MORGAN (John A. Roeblings' Sons Company). *Mining Congress Journal,* Vol. 17, Mar. 1931, pages 155-159, 163.
Detailed description of fabrication of wire rope in Roeblings' plant, Trenton, N. J. Wire rope consists of iron or steel wires, laid into strands, and these strands are closed around a hemp wire-rope center. The steel is made in an open-hearth furnace; the charge consists of pig iron, iron ore, and scrap. The name "crucible cast steel," given to one grade of wire rope is erroneous, for no steel for wire rope is made in a crucible. Acid open-hearth steel is the best material; "acid" refers to the furnace lining and process only. Process from the initial casting into ingots and completely through the wire drawing is given. Discussion of factors governing wire rope service, life, costs, wire rope attachments, lubrication, and the proper time to remove ropes from service is pointed out along with various illustrations. DTR (17)

Advance of Electrolytic Copper Production with Special Reference to the New Copper Electrolysis of the Zinnwerke Wilhelmsburg. (Die neuere Entwicklung der elektrolytischen Kupfergewinnung unter besonderer Berücksichtigung der neuen Kupferelektrolyse der Zinnwerke Wilhelmsburg, G. m. b. H.) G. EGER. *Die Metallbörse,* Vol. 20, Sept. 15, 1931, page 1738.
The new installation at Wilhelmsburg is described: capacity = 50 tons of electrolytic Cu, current density = 10,000 amps. Number of tanks = 220. Paper before the Deutsche Gesellschaft für Berg- und Hüttenleute, 1931. EF (17)

The New Lead Refinery and Its Operation at the Bunker Hill Smelter. A. F. BEASLEY, J. B. SCHUETTENHELM & J. W. JOHNSON (Bunker Hill & Sullivan Smelter). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 11 pages.
Describes the plant completed about March, 1930. It is equipped with 6 105-ton drossing kettles, 2 350-ton softening furnaces, 3 225-ton desilverizing kettles, 2 250-ton refined-lead storage kettles, 1 75-ton residue furnace and a Newman-type casting wheel. The particular steps in the refining operation are described. The man-hour output per day of Pb and Ag is 4.6 tons and 550 oz. respectively. JLG (17)

Produces Engines for Automotive Marine and Industrial Purposes. EDWIN BREMER. *Foundry,* Vol. 59, Nov. 1, 1931, pages 40-43; Nov. 15, 1931, pages 31-34.
A series of 2 articles describing the methods employed in the foundry of the Buda Co., Harvey, Ill., makers of 4 and 6 cylinder gasoline engines. The first article deals with the casting of motor blocks; while the second is concerned with the production of flywheels, flywheel housings, gear case covers and castings for Diesel engines. VSP (17)

Castings Play Important Part in Lighting Fixtures. NORMAN F. HINDLE. *Foundry,* Vol. 59, Dec. 15, 1931, pages 18-21.
Description of the plant and designing department of the Kayline Co., Cleveland. Types of patterns depend on the ease of working the design in the material required. Metals used include Ni, Au, brass, bronze, Al and Richelieu bronze. Few cores are used because the patterns are designed to leave their own green sand molds. VSP (17)

Non-Metallic Minerals and Industry. W. M. GOODWIN. *Iron and Steel of Canada,* Vol. 14, Nov. 1931, pages 167-169, 171; Dec. 1931, page 184.
A description of various plants located at Shawinigan Falls, Quebec, which is one of the most important and most rapidly growing electro-metallurgical centers of Canada. Reference is made, among others, to the plant of the Northern Aluminum Company and to the Arvida works of the company where electrical transmission cables of aluminum are manufactured. The works of Shawinigan Stainless Steel and Alloys, manufacturers of Duriron, are also mentioned. OWE (17)

MACHINERY & SUPPLIES (18)

Blast Furnace Blower. *Engineering Progress,* Vol. 13, Jan. 1932, page 17.
Illustrates and very briefly describes a blower capable of delivering 64,000 ft.^{3} of air per minute. RHP (18)

Electrohydraulic Operator has many Applications. *Steel,* Vol. 90, Feb. 22, 1932, page 26.
The apparatus is used for a smooth straight-line thrust in one direction for a definite distance and consists of a piston providing the thrust actuated by oil pressure which is supplied by a small oil pump impeller. Its use with a toggle drawing press, brakes, wire strander and in a welding installation is illustrated; it is operated by push-buttons. Ha (18)

BIBLIOGRAPHIES (19)

A Résumé of Published data on Steel Foundry Practice. A. H. DIERKER & H. B. KINNEAR. *Engineering Experiment Station, Ohio State University, Circular* No. 25, 1931, 56 pages, price $1.00.
Fairly extended abstracts of 109 selected articles bearing on the general subject of "factors affecting the surface of steel castings." These are separated into a group dealing with the metal and the furnace practice, one dealing with molding and core sand, and one with general foundry practice. Shrinkage is given particular attention. The relatively small number of abstracts of articles published in other languages than English appear to be taken from other abstracts rather than from the originals. Those of articles in English are chiefly original and more complete than most other published abstracts. The available German information appears to be inadequately covered. The compilation is a useful, but not a complete, résumé of the subject. It was prepared for a committee of the American Foundrymen's Association. HWG (19)

Chromium Plating Literature. L. H. DECKE. *Brass World,* Vol. 28, Feb. 1932, pages 23-24.
Abstracts of articles and reviews of books on this subject from 1930 to the present time. This installment covers adhesion, with later ones to include "applications," "nickel sub-coats," "passivity," and "general." WHB (19)

Morphology and Occurrence of Pyrite. (Pyritformen und Fundorte.) L. TOKODY & K. ZIMANYI. *Zeitschrift für Kristallographie,* Vol. 80, Oct. 1931, pages 255-348.
The crystallographic occurrence and origin of pyrites is exhaustively treated. 706 references. EF (19)

The Radio-active Constants up to 1930. (Die radioaktiven Konstanten nach dem Stand von 1930.) *Physikalische Zeitschrift,* Vol. 32, Aug. 1, 1931, pages 569-581.
Report of the International Standard Committee compiling all data available on the radio active constants up to 1930. Includes several bibliographies. EF (19)

Bibliography of Bibliographies on Chemistry and Chemical Technology. Compiled by CLARENCE J. WEST & D. D. BEROLZHEIMER. *Bulletin 86, National Research Council,* 1932. Paper, 6½ x 9¾, 150 pages. Price $1.50.
Bulletin 86 is the Second Supplement to the Bibliography of Bibliographies on Chemistry and Chemical Technology covering the period 1929-1931. The original Bulletin (No. 50) covered the period 1900-1924 and contained about 10,000 bibliographies classified under 2400 headings. The First Supplement (No. 71) covered the period 1924-1928 and contained about 4000 bibliographies under 1050 headings. The Second Supplement (No. 86) covers the period 1929-1931 and contains approximately 3300 bibliographies under 950 headings.
As the title indicates, the work (as in the case of Bulletins Nos. 50 and 71) is a compilation of bibliographies published as separates, or at the end of books or magazine articles, or as footnotes to the same, on the numerous aspects of pure and applied chemistry. Each entry gives name of author or compiler, title, and place of publication. The majority of the entries state the number of references, thus giving an indication of the completeness of the particular bibliography. The entries are classified under the proper subject-headings, alphabetically arranged. The duplication of individual entries has been largely avoided by the liberal use of cross references. (19)-B-

International Scientific and Political Bibliography. (Bibliotecn Scientifico-Politecnica Internazionale). Hoepli, Milan, 1932. Paper 4¼ x 8½ in., 528 pages. Price 10 Lire.
The book is a compilation of the more important Italian and foreign books published from 1926-1931. It is arranged by subject, with excellent cross references and an author index at the end. The majority of the titles are annotated and the date of publication and collation information is included. Although it is not entirely complete, the information it contains is accurate and worthwhile to have. Forty-eight references are given under metallography and metallurgy. A 10% discount is allowed from the list price and 20% on some of the English works. The volume would be worth its price in most libraries. T. R. Reinberg (19)-B-

MISCELLANEOUS (20)

Shipbuilding and its Relation to the Steel Industry. H. Gerrish Smith. *Engineering*, Vol. 131, June 19, 1931, pages 801-802.

Paper read before the American Iron & Steel Institute, New York, May 1931. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 218. LFM (20)

Plasticity, A Mechanics of the Plastic State of Matter. (Revised and enlarged from the first German edition.) A. Nadai, assisted by A. M. Wahl. *Engineering Societies Monograph.* McGraw-Hill Book Co., Inc., New York, 1931. Cloth, 6 x 9¼ inches, 349 pages. Price $5.00.

The English translation of the German is skillfully rendered and in enlarging the edition, some of the most recent information pertaining to the plastic state of matter is included.

In presenting the subject-matter of the book, Dr. Nadai has made two broad divisions. The major study and the most interesting from the view point of the engineer is devoted to the plastic state of matter with special reference to metals and to mechanical engineering problems. In the latter part of the book some applications of the mechanics of the plastic state of matter to geology and geophysics are presented.

The author introduces the concept of plasticity without actually defining the term and its limitations. He then proceeds to give a descriptive analysis of such points of interest as elastic and permanent deformation, and the mechanism of plastic deformation in the grain structure. Though this analysis is of special interest to the metallurgist, it is covered somewhat hurriedly. From this point, the book becomes a highly mathematical treatise and to those familiar with theoretical and applied mechanics, it is a valuable contribution. This is especially true of the chapters dealing with stress, strain, theories of strength and related tests and tension. Some fine photographs of strain or flow figures in steel, paraffin, marble and copper specimens under tensile, compressive or torsional loading illustrate the stress distribution under the conditions cited.

A few observations relative to the plastic deformation near the regions of contact of materials deformed by indentations in various ways are given in a chapter on hardness. It is recognized that various metals behave very differently when an indentation is made by a punch but nothing is offered as a possible cause for the behavior.

There are some very interesting figures to illustrate the similarity of the slip lines produced by a punch in steel and the slip lines determined by photo elastic tests occurring in celluloid plates under a rigid punch.

On the application of the mechanics of the plastic state of matter to geology and geophysics, Dr. Nadai takes one into a field quite apart from that of metals. Here pressures of enormous magnitude exist that play an important role in the observed behavior of rock movements. Such subjects as the pressure in the earth's interior, mountain building, the origin of rock-salt domes, the weight of the continents and the traces of motion in the structure of rocks are treated in an interesting way.

To the engineer interested in applied mechanics, the book is highly valuable. To the metallurgist who is seeking for new knowledge on the physics of crystals as a guide in looking for the mechanism of the plastic behavior observed in metals, and in predicting new properties the book will undoubtedly be somewhat disappointing. C. H. Lorig (20)-B-

The Phenomenon of Slip in Plastic Materials. A. Nadai. *Proceedings American Society for Testing Materials*, Vol. 31, Pt. 2, 1931, pages 11-46.

See abstract of preprint. *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 49. HWG (20)

Plastic Deformation and State of Deformation. (Verformung und verformter Zustand.) M. Polanyi. *Die Metallbörse*, Vol. 21, Dec. 2, 1931, page 2075.

Extract of a lecture in the Haus der Technik, Essen, Nov. 1931. Compares the behavior of crystalline and amorphous materials with reference to their plasticity. The difference becomes most obvious at extremely low temperatures where crystals do still exhibit plasticity. EF (20)

Radium in Rocks. C. S. Piggot & H. E. Merwin. *American Journal of Science*, Vol. 23, Jan. 1932, pages 49-56.

2 granites of high radium content were separated into their component minerals and these examined in detail for radium. The radium is associated much more with the micas, weight for weight, than with the other components of the rock. Why this should be is not evident. Hot water removes from most powdered specimens some of the emanation in equilibrium with the radium present but apparently does not affect the radium, and probably not the parent uranium. It did not affect the radioactivity of one biotite at all. The radioactivity of leached samples was completely restored after 30 days. WAT (20)

On the Action of Iron and Nickel on (Fused) Alkali Metal Salts. (Action du fer et du nickel sur les sels alcalies.) L. Hackspill & H. J. Pinck. *Bulletin de la société chimiques de France*, Vol. 49, Jan. 1931, pages 54-70.

The alkali metals are formed by heating the sulphates, arsenates, phosphates, borates, and aluminates with Fe in a vacuum at or above the melting point of the salt. Li is obtained, however, only from the oxide or silicate under these conditions. Ni displaces the alkali metals only from their hydroxides or sulphides. WHB (20)

Recent Testing Results on the Plastic Behavior of Metals. (Neuere Versuchsergebnisse über das plastische Verhalten der Metalle.) K. Hohenemser. *Zeitschrift für angewandte Mathematik und Mechanik*, Vol. 11, Dec. 1931, pages 423-425.

The speaker at the 7. Deutscher Physiker- und Mathematikertag, Bad Elster, Sept. 1931, summarizes the investigations and mathematical interpretations of the Institut für angewandte Mathematik der Universität Göttingen regarding the behavior of metals during plastic deformation. In more recent theoretical derivations the strain hardening effect is taken into account. Further publications are under way. EF (20)

The Diffusion of Cathodically Developed Hydrogen Through Iron. (Die Diffusion des kathodisch entwickelten Wasserstoffs durch Eisen.) A. H. W. Aten & P. C. Blokker. *Recueil Travaux Chimiques Pays-Bas*, Vol. 50, July 15, 1931, pages 943-950.

Poisons greatly accelerate the diffusion through the cathode and increase its velocity. The effect of $HgCl_2$ was studied in electrolytes of H_2SO_4 and NaOH, both 0.1 *N*. A small quantity of $HgCl_2$ (1-2 cc. 0.01 *M*) markedly increased the diffusion velocity. A large amount slightly lowered it. The latter effect was more marked the higher the current density. Curves of cathode potential showed a parallelism to those of diffusion velocity, the more negative the potential the greater the diffusion velocity. Diffusion through Ni-Fe and Cr-Fe in an electrolyte of 0.1 *N* H_2SO_4, with and without As_2O_3 as a poison, is measured and the results are given. Equations for the diffusion velocity and potential are developed and discussed. No satisfactory explanation is given of the interdependence of current density potential and diffusion velocity. Car Scrapping by the Line Production Method. T. M. Hamer. *Paper read before the 32nd Annual Convention, International Acetylene Association*, Chicago, Nov. 1931, 5 pages.

Discussion whether scrapping is done better by a railway company itself or to have it done by outsiders. Ha (20)

Plastic Deformation and Its Underlying Law. (Plastizierung und ihre Gesetzmässigkeit.) O. Manfred. *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 15, Jan. 1932, pages 383-387.

The author summarizes his paper on "Plastizierung" (i.e. 'the work, or procedure which carries a solid material by permanent deformation above the limit of elasticity into the range of flowing or plastic deformation") as follows: Between the degree of plastification ("Plastizierungsgrad") and physical properties of any material a functional relationship exists insofar as with increasing degrees of plastic deformation the physical properties are improving independent from the structure of the material. A table is included in the paper showing the strain hardening effect in non-metallic materials, in Cu and wrought Fe. Stress is laid on tests of Reinkober (*Physikalische Zeitschrift*, Vol. 32, Mar. 15, 1931, page 243) on glass and quartz clearly proving that, irrespective of the crystalline or colloid-plastic nature of the testing material, a strain hardening effect or improvement of physical properties takes place due to stretching. EF (20)

The Oxidation of Phosphorus Vapor at Low Pressures in Presence of Platinum and Tungsten. H. W. Melville & E. B. Ludlam. *Proceedings Royal Society*, Vol. 135A, Mar. 1932, pages 315-333.

The actions of hot filaments of Pt and W on mixtures of P vapor and O at pressures smaller than the lower explosion limit has been investigated in some detail. With Pt it was found that the reaction rate is conveniently measurable with the filament at a temperature of about 200° C. The reaction velocity is directly proportional to the O pressure. Argon is without influence on the rate of the reaction. No glow is emitted during the oxidation. The reaction therefore occurs at the Pt surface. With the W filament at 500° C. the rate of the reaction can be conveniently measured. This rate is proportional to the pressure of the O and the P. A green glow accompanies the process of the reaction. The reaction thus probably starts on the W side, is propagated through the gas phase and finally ends on the wall of the reaction tube. Au, Ag, and Mo behave similarly to W, but have not been studied in detail. WAT (20)

Making Expansion Fits with Liquid Air. E. V. David & W. S. Farr (Air Reduction Sales Co.). *Machinery*, Vol. 38, Nov. 1931, pages 189-192.

Liquid air is used in cooling the inner member so it will contract. It is then inserted in the outer member and expands to fit. This method is useful when the inner member is light compared to the outer member or when heating will warp or crack the part. Liquid air varying from 40% liquid oxygen and 60% liquid nitrogen to 60% liquid oxygen and 40% liquid nitrogen may be used. Its boiling point may be taken as —310° F. 200 B.t.u. are required to evaporate one liter of liquid air. The following table gives data for determining approximate amount of liquid air evaporated in cooling metals.

Kind of Metal	Weight of Metal/in.3 lbs.	Heat given off/lb. of metal cooled B.t.u.	Weight of metal cooled /liter of liquid air evaporated lbs.	Amount of liquid air evaporated /lb. of metal fully cooled liters
Aluminum	0.098	71.4	2.80	0.357
Brass	0.310	33.1	6.04	0.166
Bronze	0.323	34.2	5.85	0.171
Cast Iron	0.260	39.5	5.06	0.198
Copper	0.322	29.7	6.73	0.148
Monel metal	0.318	34.2	5.85	0.171
Nickel	0.317	34.6	5.78	0.173
Steel	0.285	34.6	5.78	0.173

Also gives tables showing linear contraction per in. from 70° F. to —310° F. for these metals. Linear expansion when heated from 70° F. to 212° F. for the same metals. Table of allowances and tolerances for sliding fits. Shipping of liquid air. Estimation of evaporation in shipping and handling. Lists precautions and gives instructions for handling liquid air for expansion fits. See also *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 74. RHP (20)

The Dangers in the Production of Aluminum Powder and Their Prevention. (Die Gefahren bei der Herstellung von Aluminiumpulver und ihre Verhütung.) Bethke. *Feuerschutz*, Vol. 11, Apr. 1931, pages 65-66.

The causes of ignition can be: open flames, electric sparks, hot wires, impact, friction, hot bearings, self-ignition by oxidation. The flames are best extinguished by airtight covering with sand. Ha (20)

FOUNDRY PRACTICE & APPLIANCES (22)

Methods for Testing of Molding Sands. (Les methodes actuelles d'essai et de controle des sables de moulage.) A. DELEUSE. *Revue de Metallurgie,* Vol. 28, May 1931, pages 281-283. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 22. JDG (22)

Bronze Pressure Castings. J. E. CROWN. *Transaction & Bulletin American Foundrymen's Association,* Vol. 2, Nov. 1931, pages 496-505.
Factors involved in the successful production of bronze castings for pressure service are: selection of alloys, design of pattern, method of molding, types of heads and gates. The alloy contains 87.25% Cu, 9% Sn, 3% Zn and 0.75% Ni. Average pouring temperatures are 1950° F. See also *Metals & Alloys,* Vol. 2, Dec. 1931, page 321. CHL (22)

Evolution in the Foundry; Molding in Snap-Molds. (Evolution de la Fonderie; le Moulage par Mottes.) M. CONSTANT. *Revue de Fonderie Moderne,* Vol. 26, Mar. 10, 1932, pages 84-87; Apr. 1932, pages 138-140.
A method for molding pieces of a form too complicated for machine molding is described whereby proper sectioning of the mold is paid particular attention in order to save time in molding if a larger number of pieces is to be cast. The process is illustrated by an example; parts of the mold can be made by machine. Ha (22)

Mold-Blacking. (Formschwärze.) E. FEIL. *Die Giesserei,* Vol. 19, Feb. 5, 1932, pages 41-46.
A testing method is described for testing the gas permeability and strength of the blacking which is used in molds to give the castings a smooth surface. The tests showed that the blacking has to be adapted to the kind of casting; very massive castings require a blacking of higher strength. Also the thickness of the coating is of importance for the permeability of gas. Ha (22)

Arrangement of the Pattern and Making of the Mold of a Grate Bar of a Locomotive of Special Construction. (Modelleinrichtung und Herstellung der Form eines Lokomotivroststabes besonderer Konstruktion.) K. GROCHOLL. *Die Giesserei,* Vol. 19, Feb. 19, 1932, pages 71-72.
Description of the pattern and procedure of molding. Ha (22)

European Iron Founders Use Rotary Furnace. Correspondence from F. GIOLITTI. *Metal Progress,* Vol. 21, Apr. 1932, pages 72-73.
European foundrymen are turning to revolving furnaces of the Brackelsberg type for the production of high grade alloy cast Fe. Revolving furnaces are frequently duplexed with the cupola. A Brackelsberg furnace of 1½ T. capacity can supply 3200-3500 lbs. of Fe of predetermined composition at 3000° F. at 40 minute intervals using sluggish cupola iron at 2300° F. WLC (22)

A Study of Molding Sands. (Etude des Sables de Moulage.) L. GASQUARD. *Revue de Fonderie Moderne,* Vol. 26, Mar. 25, 1932, pages 95-104.
Testing methods and determinations of the structure of sand grains are described, the advisability of recuperation and regeneration of used sands is discussed. An addition of kaolin improves a molding sand. Methods of separation of sand, Fuller's earth and colloidal matter in molding sands are described. It is best done by a kind of floating process. Ha (22)

Casting in Oblique Position of the Mold. (Das Giessen in Schräglage der Gussform.) H. KALPERS. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Mar. 5, 1932, page 247.
To avoid unevenness of the surface in long castings of more than 50 mm. thickness a slight tilting of the mold is recommended instead of the usual horizontal position of the mold. Ha (22)

Progress in Foundry Practice in Last Half 1931. (Fortschritte des Giessereiwesens im Zweiten Halbjahr 1931.) HANS JUNGBLUTH & PAUL A. HELLER. *Stahl und Eisen,* Vol. 52, April 28, 1932, pages 412-414; May 5, 1932, pages 446-448.
Summary of foundry practice progress for 2nd half of 1931. 76 references. Divided into groups, (1) Casting and Properties of Cast Iron; (2) Melting; (3) Molding and dressing; (4) General. DTR (22)

Green Sand Steel Castings (Stahlnassguss). R. GENWO. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Feb. 21, 1932, pages 75-77.
The article deals with the molding sand to be used for green sand steel castings and the molding practice with special reference to the arrangement of the gates and risers. As to the molding sand a sufficient porosity is of extreme importance. GN (22)

Malleable Iron with Black Core and the Open-Hearth Furnace. (Malleable a coeur noir et Four a Sole.) CHR. KLUIJTMANS. *Revue de Fonderie Moderne,* Vol. 26, Mar. 25, 1932, pages 105-108.
If malleable iron is made in the open-hearth furnace the determination of proper temperature and desired analysis should be made at the time of pouring and not long before. This requires testing methods giving immediate results. The proper temperature can, according to the author, be determined much more accurately by the eye than with a pyrometer; a sample is removed from the furnace and put on the ground, from color and reflection, for which he gives directions, the temperature is determined. A table is given for the ratio of C to Si and the respective pouring temperatures, the fracture of the sample is compared with a table showing the appearance of fractures at different temperatures from which it can be judged whether the proper pouring temperature exists. The method is explained in detail. Ha (22)

Some Observations on Preparation and Use of Synthetic Sand. L. B. KNIGHT. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 3, Jan. 1932, pages 718-728.
Methods of preparation of synthetic molding sands are described. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. CHL (22)

A Grain Distribution Index for Sand Grading. CLARENCE E. JACKSON. *Transactions & Bulletin American Foundrymen's Association,* Vol. 2, Nov. 1931, pages 506-512.
Previous methods of grading are reviewed and present development of the A. F. A. grading classification is briefly discussed. A method is developed, based on statistical analysis, that yields a numerical value for a grain distribution index. CHL (22)

FURNACES & FUELS (23)

The Present State of High Frequency Induction Furnaces. (L'etat actuel du four a induction a haute frequence.) J. Minssieuz. *Journal du Four Electrique,* Vol. 41, Mar. 1932, pages 98-102; Apr. 1932, pages 137-140.

A survey is given of the position occupied by high frequency furnaces in the industry. France and England favor ramming dry lining around a steel core placed in the induction coil. Germany sometimes uses damp linings rammed around a wooden core. The capacity of convertor sets is usually equal to the furnace capacity so as to melt the charge in about 1 hour. Sometimes it is more advantageous to use smaller transformers although it slows the melting time and cuts down the efficiency. In a 250 kg. furnace the current consumption varied between 525 and 698 kwh/ton, with an average of 610 kwh/ton for 0.8 C steel and 530 kwh for high speed steel. Examples of the flexibility of the furnace are given. JDG (23)

Investigation of Electric Furnaces for Transition Heating. (Untersuchung elektrischer Oefen für Uebergangsheizung.) Karl Meyer. *Elektrotechnische Zeitschrift,* Vol. 53, Mar. 21, 1932, pages 315-318; Apr. 14, 1932, pages 362-364.

By determining the temperature distribution in the interior of furnaces as a function of time, measuring air velocities and radiation, more exact data than have been available are collected for the design of electric furnaces. A number of examples show the application of the results to the heating of furnaces and rooms. Ha (23)

Solid and Gaseous Fuels in the Iron and Steel Industry. Harald Nielsen. *Fuel Economist,* Vol. 7, Apr. 1932, pages 279-285.

Fuel costs can be reduced in the ferrous industry by utilizing low grade coal, drying it and distilling it at low temperatures. A flow sheet is given showing operations for the production of powdered fuel, producer gas and crude oil. DTR (23)

The Technical Heat Efficiency of a Furnace. (Der feuerungstechnische Wärmeaufwandsgrad eines Ofens.) Gustav Neumann. *Archiv für Eisenhüttenwesen,* Vol. 5, March 1932, pages 471-475.

Report 160 of Heat Section of Verein deutscher Eisenhüttenleute. A résumé is given of 12 important heat formulae for use in the computation of furnace efficiencies, heat losses, heat consumption, etc. DTR (23)

Use of Powdered Coal in the Foundry. (Emploi du Charbon Pulverise en Fonderie.) R. Moine. *L'Usine,* Vol. 41, Feb. 5, 1932, page 27.

The use of powdered coal in the foundry has many advantages. In annealing castings 1 man can operate 6 furnaces of 30 tons each. The desired temperature can be reached rapidly and controlled easily, as can also the furnace atmosphere. A comparison with other fuels shows a saving of 15 to 20% in cost. Ha (23)

Commercial Evaluation of Coke. R. A. Mott. *Journal Institute of Fuel,* Vol. 5, Feb. 1932, pages 193-210.

Coke production in Great Britain and the future demand for oven-coke are discussed. Demand for coke for pig-Fe manufacture depends on the development of the steel industry. On the basis of development for 1900-1918 steel production in Great Britain should be 16,000,000 tons in 1940, requiring 16,000,000 tons of coke. Coke consumption/ton of pig-Fe has been influenced more by the price of coke than by the amount of ore used. When the price of coke has risen, the quality has deteriorated, and vice versa. To protect the Fe manufacturer from deterioration in quality, a sliding-scale basis of payment for blast-furnace coke is suggested. This would be of benefit both to the coke maker and user. Except for hematite-pig production, S is not of sufficient importance to warrant its introduction into a coke specification. For hematite pig, low-S coke is desirable, but it is not possible to evaluate it at present. P is only of significance when pig for acid steel production is being made, for which use coke should not contain more than 0.01% P. Cokes with a ½" shatter index of less than 97.0 should not be used in blast-furnaces. Foundry coke should have low moisture, less than 8% ash, less than 1% and preferably less than 0.8% S, and a 1.5" shatter index of over 90. Beehive coke is preferable for crucible steel melting. Includes discussion. MS (23)

Stoker Fired Furnaces for Metallurgical Work. *Fuel Economist,* Vol. 7, Jan. 1932, pages 128-130.

Operation of the Hagan stoker is described and the underlying principles discussed. This stoker was specially developed as a substitute for hand-fired grates and metallurgical furnaces. Advantages as compared with hand-firing are: (1) A cheap slack coal may be used; (2) fuel saving of 10 to 23%, due to regular feed and system of combustion, are possible and the furnace may be brought up to temperature rapidly; (3) due to even rate of firing, any heating operation can be conducted on a definite time cycle; (4) the amount of dust carried over into the furnace chamber is reduced greatly over both hand-firing and overfeed mechanical stokers; (5) upkeep charges are extremely low; (6) possibility of breakdown during working may be neglected; (7) clinker formation is confined to the firebars at the sides, where it may be removed easily. The use of preheated air is stated to be beneficial. The Stein suspended arch is referred to and illustrated. DTR (23)

Oil-Fired Brass-Melting Furnace. R. S. Livingston. *Engineering & Mining Journal,* Vol. 133, Feb. 1932, page 77.

A simple oil-fired furnace claimed to produce rapid smelting of the charge, or superior grade of brass, and economies in fuel and labor (perfected at the Uvalde Rock Asphalt Co., Blewett, Tex.) is described and illustrated. The welded sheet-Fe shell and burner were made from scrap Fe, standard firebrick formed the lining, and the burner was a 2" tee with a short pipe nipple connected by reducers to the 1" air line and to the ⅜" oil line. Atomized oil is blown into the combustion chamber by the injector and the 1" air connection on the flue end of the furnace serves to control the draft. A heavy Fe lid covers the melting chamber and reduces heat losses. WHB (23)

Steel Recuperators for Heating Mixers. (Stahlrekuperatoren zur Mischerbeheizung.) *Demag Nachrichten,* Vol. 6, Mar. 1932, pages 13-15.

A steel recuperator is described which simultaneously preheats gas and air to be used for heating a mixer, or only air if used for other purposes. The recuperator gives air temperatures of 800° C. For heating a mixer, the gas can be heated simultaneously to 300° C. The maximum temperatures which can be attained amount to 900°-950° C. GN (23)

Application of Coke Oven Gas in the Open Hearth Plant and in the Steel Foundry. (Verwendung von Ferngas im Siemens-Martin-Stahlwerk und in der Stahlgiesserei.) Erich Matejka. *Stahl und Eisen,* Vol. 52, May 19, 1932, pages 481-489.

Combustion reactions and sources of heat losses are discussed and the advantages of gas firing pointed out, together with the effect of various kinds of gas burners. A typical open hearth layout using cold coke-oven gas is described. A high pressure gas line serves the foundry drying and annealing furnaces while a low pressure line serves the open hearth mill and miscellaneous places, such as tempering units, laboratory, etc. The maximum allowable pressure drop along any line is 500 mm. of water with gas velocities approximately 20 to 25 m./sec. Plant costs for gas installation, fuel requirements and economy are enumerated. (23)

Costs Cut in Half When Nitriding in Bell Furnaces. Willard Roth. *Metal Progress,* Vol. 21, May 1932, pages 40-43.

The bell-type nitriders made by the Westinghouse Company are described and operating costs given. Time-temperature cycles and hardness penetration curves for work done in this equipment are drawn. WLC (23)

Electric Annealing and Hardening Installations. (Elektrische Glüh- und Härtanlagen.) Victor Paschkis. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Apr 9, 1932, pages 359-363.

Some new developments in heating resistances and their mountings on the furnace walls, charging devices and heat transmitting arrangements are reviewed and illustrated. (23)

View Points on Electrical Heat Policy. (Gesichtspunkte über Elektrowärmepolitik.) E. Fr. Russ. *Elektrowärme,* Vol. 2 Jan. 1932, pages 2-4.

Electrical heating is of value for industrial purposes because the heating value of electric energy never varies; it is always 860 kg.cal./kwh., whereas all other fuels show fluctuations. Electrical energy can be produced from even the lowest-grade fuels while fuel gases require high-grade coal for their manufacture. For further progress the standard furnace types should be developed so that their price is reduced, second, ideas should be exchanged between furnace manufacturers, and third, testing institutes with laboratories should be created. Ha (23)

Electric Continuous Furnace for Annealing Hoops. (Elektrischer Durchziehofen zum Glühen von Metallbändern.) E. F. Russ. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Feb. 28, 1932, page 118.

A brief description is given of a continuous electric annealing furnace, system Russ, built by the "Industrie" Electrofen G.m.b.H., at Cologne, Germany. The temperature controller used allows the temperature to be regulated so that the fluctuations do not exceed more than ± 5° C. GN (23)

High-Temperature Furnaces with Flameless Surface Combustion. (Hochtemperatur-Oefen mit Flammenloser Oberflächenverbrennung.) Rudolf Schnabel. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Feb. 27, 1932, pages 213-214.

Flameless surface combustion is a process for the combustion of gases in which glowing surfaces energetically accelerate the combustion reaction. A mixture of gas and air is driven through a layer of small pieces (pebbles) of refractory ceramic material and burnt in this layer. The gas mixture is ignited at the surface; the combustion, due to the high ignition velocity, goes spontaneously into the interior of the layer; the whole layer in short time is a glowing mass. Muffles, or other containers can be embedded in the refractory mass to utilize the heat. These furnaces are said to have a very high thermal efficiency; several constructions are described. Ha (23)

Vacuum Electric Furnaces in the Manufacture of X-ray Apparatus. (Le four électrique à vide dans l'industrie radiologique.) R. Sevin. *Journal du Four Electrique,* Vol. 41, Apr. 1932, pages 133-136.

Structural features of a C resistance furnace able to operate at about 0.01 mm. pressure at 1800° C. are given. The furnace is rated at 34 kw and was in use for several years for regasifying metals used in vacuum tube construction. JDG (23)

Coreless Electric Induction Heating. (Elektrische Induktionsheizung ohne Eisenschluss.) W. F. Scher. *Die Naturwissenschaften,* Vol. 19, Dec. 4, 1931, pages 974-980.

The principles of low frequency and coreless high-frequency furnaces are discussed. The phenomena in the latter type of furnaces is demonstrated by the current density distributions in a Cu bolt at various frequencies, which is covered by the formula $q = \pi d \sqrt{2 f \mu H 10^{-9}}$, wherein d = diameter of the Cu bolt, f = frequency of current, μ = permeability, H = conductivity of charge, q = parameter. The heat efficiency N is given by two formulae; if $q < 2$ then $N = \text{const.}\ q^4/H = \text{const.}\ d^4 f^2 \mu^2 H$; if $q > 5$ then $N = \text{const.}\ q/H = \text{const.}\ d \sqrt{\frac{f \mu}{H}}$. The effect of the various factors on the heat efficiency is discussed. Temperature measurements on a steel block are reported which show the influence of the permeability, i.e., a sharp break of the curve due to the appearance of γ-Fe at 720° C. Much attention is paid to the influence of the diameter of pieces of the charges, since the efficiency drops with the fourth power if one goes below the critical value $q = 2.5$. The most favorable diameters of the charged bodies in relationship to the frequencies (50 to 500,000 cycles) are tabulated for the following materials: Cu cold, Fe cold, Pb, Cu liquid, Fe 800° C. and graphite. The high frequency generator and condenser for compensating the reactive volt amperes are discussed. The application of coreless high-frequency furnaces to metallurgical purposes offers great advantages which are dealt with at length in a critical comparison with other furnaces. EF (23)

Vertical Muffle-Annealing Furnace. (Senkrechtmuffelglühofen.) W. Stieding. *Stahl und Eisen,* Vol. 52, Mar. 31, 1932, page 316.

A muffle-annealing furnace for handling special steel sheets, 3500 x 1200 or 3500 x 1600 mm. 1.5 to 2 mm. thick at annealing temperatures of 1050-1160° C. is described. The furnace hearth surface is 1800 x 5000 mm. DTR (23)

Use of Powdered Coal in German Foundries. (L'Emploi du charbon pulverise dans les fonderies de malleable allemandes.) Stotz. *Revue de Metallurgie,* Vol. 28, May 1931, pages 271-275.

See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 24. JDG (23)

Electric Varnish Drying Furnaces. (Elektrische Lacktrockenöfen.) K. Tamele. *Elektrowärme,* Vol. 2, Jan. 1932, pages 16-22.

The advantages of electric furnaces for drying lacquered and varnished articles are explained and several installations described. Ha (23)

Recent Developments in Gas Burners. W. Trinks. *Heat Treating & Forging,* Vol. 18, Jan. 1932, pages 45-47, 55; Feb. 1932, pages 121-123; Mar. 1932, pages 194-196; *Blast Furnace & Steel Plant,* Vol. 20, Mar. 1932, pages 274-279; Apr. 1932, pages 352-354.

The design of induction and luminous-flame burners is discussed, including cylindrical induction burners of the high-pressure type in which gas under pressure induces air, and the low-pressure type in which air induces gas, Venturi, 2-stage and multi-stage types. The constancy of the air-to-gas ratio is considered. MS (23)

Heat-Transfer in Non-Ferrous Metals in Heat-Treating Furnaces. (Der Wärmeübergang an Nichteisenmetallen im Wärmofen.) G. Wagener. *Zeitschrift für Metallkunde,* Vol. 24, Feb. 1932, pages 35-39.

The heat-transfer coefficients for non-ferrous metals are considerably less than that for Fe because of the diminished absorption of radiation by the brighter surfaces. Curves and mathematical expressions are given for the heat-transfer of Al, Cu, and brass, and compared with those for Fe. RFM (23)

Economies to be Derived from the Use of Gas Industrially. C. M. Walter. *Journal Institute of Fuel,* Vol. 5, Feb. 1932, pages 176-183.

Includes discussion. The advantages of gas as an industrial fuel are summarized. By substituting gas for coke in the production of forgings and machined and heat-treated parts, the total production costs were reduced in 2 cases, in spite of the higher cost of the gas. The savings were effected principally by the reduction of wastage of material. Recuperation and regeneration are discussed and the thermal efficiency of heat application for industrial heating operations using gas is presented tabularly. MS (23)

Furnaces Placed in Production Lines. G. T. Williams. *Metal Progress,* Vol. 21, Mar. 1932, pages 27-31.

The efficiency of the plant of the Cleveland Tractor Co. was greatly increased by placing heat treating equipment in the production line. A brief account of the type, arrangement and capacity of equipment is given. WLC (23)

Application of Gas Heat to Forging. *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1059-1061, 1068.

From the Fifth Annual Report of the Committee on Industrial Gas Research of the American Gas Association. W. E. Jominy has published data on the rate of heat penetration, and on burning and overheating of steel at forging temperatures, which show the superiority of gas over other fuels from the metallurgical point of view. Results of investigations on the scaling of steel at forging temperatures have been published by W. E. Jominy and D. W. Murphy. 6 subjects remain to be covered, including studies on the influence of 0.05, 0.1, 0.2 and 0.5% SO_2 in oxidizing and reducing furnace atmospheres on S.A.E. 1015, 1030 and 1040 steels and also on some of the more common alloy steels used for forgings. Under usual conditions, gas is at a disadvantage as compared with oil, because heat transfer is slower, an adherent scale difficult to scrape from the steel is formed and excessive furnace repairs are required. Any appreciable increase in the reducing condition of the atmosphere so as to reduce scaling was accompanied by a sharp reduction in the efficiency of the fuel as well as a reduction in the rate of heat transfer. A new method of combustion designated "diffusion flame combustion" has been evolved, in which the air for combustion reaches the gas by diffusion through the burning flame rather than by any form of premixing, causing the gas to burn with an intensely luminous flame which is highly radiant within itself. The method has been applied to forging furnaces, but it has involved the development of a new technique in burner construction and furnace design. Full-scale furnaces have been installed in several plants. Results to date indicate that the heating rate with gas using "diffusion flame combustion" may be faster than with fuel oil, the quality of the steel is superior, there is a total absence of scale, and full thermostatic control may be applied to the furnaces, giving assurance against overheating or burning of the steel. MS (23)

Smoke—A Study of Aerial Dispense Systems. R. Whytlaw-Gray & H. S. Patterson. Longmans-Green & Co., New York, 1931. Cloth, 5¾ x 9 inches, 192 pages. Price $4.50.

This book deals with the general and fundamental principles which underlie the behavior of systems consisting of fine particles dispersed in air. It does not discuss the application of the conclusions to technical questions of industrial smokes.

It deals largely with measurements of the number, size and distribution of the particles, the factors which affect these relations, and the fundamental theories involved. Precise, rather than convenient, methods are used. H. W. Russell (23) -B-

Fuel Requirements of Steel Mills. *Rolling Mill Journal,* Vol. 6, Feb. 1932, pages 51-54.

A general discussion presenting heat balances for coke-ovens, blast furnaces and melting and heating furnaces, and power and steam requirements of steel plants shows that for the best practice a total of 15,793 B.t.u. is required. Cost of fuels per 1,000,000 B.t.u. must be considered. Many heating operations can be conducted at a lower cost even with higher heat consumption by the use of a different fuel. MS (23)

Application of Waste Heat Boiler to Open-Hearth and Heating Furnaces. G. R. ADAMSON. *Iron & Coal Trades Review,* Vol. 124, Jan. 29, 1932, pages 204-205.

The value of waste heat boilers to an installation is discussed and the size of such boilers is compared to the fuel-fired boiler. Several types of modern waste heat boilers are described and their effect on furnaces explained. Even if a regenerator for preheating gas and air is used sufficient heat is still left in the combustion gases to make the installation of a waste heat boiler economical. Ha (23)

Rotary Furnaces in the Foundries of Ferrous and Non-Ferrous Metals. (L'Emploi des Fours Rotatifs dans le Dormaine des Fonderies de Métaux Ferreux et Non-Ferreux.) BOUTIGNY. *Revue de Fonderie Moderne,* Vol. 26, Apr. 25, 1932, pages 133-137.

The advantages of rotary furnaces for Fe and bronzes are pointed out. They often contribute to a more economical production of castings. The losses due to burning are negligible, the metal is completely killed and of good quality in spite of the low content of C and Si. The clay lining behaves very well under various compositions of the charge, with temperatures between 1565° and 1640° C. for 1 hr. 30 min.; the consumption of oil was 14 to 17% of the weight of the charge. The results of several test runs are given. Ha (23)

The Influence of Operating Conditions on the Manufacture of Producer Gas. (Ueber den Einfluss der Betriebsbedingungen auf die Erzeugung von Generator-gas.) M. FULDA & G. GEHLHOFF. *Glastechnische Berichte,* Vol. 10, Mar. 1932, pages 131-149.

The chemical processes in gas producers depend essentially on the temperature of the bottom zone in which the principal chemical conversions take place. In the oxidation zone the O of the supplied air combines with C to form CO_2 while the added H_2O vapor remains intact. The heat produced is utilized in the following zone in the reduction of the H_2O vapor and CO_2. The temperature of this reduction zone determines the efficiency of the gasification. Sufficient height of the column of material increases the production and the heating value of the gas. The limit of addition of steam which can be disintegrated completely in the gas producer is for all fuels about 40 kg./100 kg. of gasified C; older fuels can give a better gas with up to 77 kg./100 kg., but younger fuels do not show an improvement in quality. 35 references. Ha (23)

Recent Improvements on Cupolas which have been Tried Previously. (Altes als Neues beim Kupolofenbetrieb.) H. KLOSS. *Feuerungstechnik,* Vol. 19, Oct. 15, 1931, pages 156-158.

Historical proof is presented that recent improvements in cupola operations are not really new ideas. Such improvements include the preheating of the blast, special arrangement of the tuyères, large output by special copula profiles, and stamping out of the cupola bottom. EF (23)

Means to Increase Temperatures in the Open Hearth Furnace. A. J. BOYNTON. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 66-70.

The advantages in using mixed gases as open-hearth fuel are discussed. High temperature is most essential in the melting state of the open-hearth process and in the sub, sequent clearing stage which precedes the boil. These high furnace temperatures can be attained with a minimum use of fuel by means of a new development of open-hearth regenerator. For dissociating the hydrocarbons of the mixed gases, air and gas are regenerated above 2100° F. The furnace should be provided with means of allocating the exit gases between the air and gas regenerators. The latter should be larger in proportion to the air regenerator, than has been the custom with producer gas, the proportionate size being 1.25-1.40 air to 1.00 gas. Regularity of regenerator temperatures is a highly desirable condition which is not fulfilled by the ordinary type of regenerator. The principles of the Brassert regenerator, which have been applied to the blast furnace stove, have been applied to the open-hearth regenerator. The checkers are Peterson-type open checkers, varying in length, but with width and thickness constant in the successive zones of the first pass. The openings are successively reduced in area. This maintains velocity and promotes turbulence, while also adding to brick weight and heating surface. In the second pass, the checkers are open-type and 4 in.² In this pass, inserted checkers are used, full star-shaped checkers being used in the bottom zone, intermediate shape in the middle zone, and plain diagonal in the top zone. An induced draft fan is required. This construction has 65% more heating surface and 60% more weight of brick than a standard open-checker made of standard 9" brick. To maintain high temperatures it is necessary to prevent infiltration of air. As it is not possible to make a furnace air or gas tight, the furnace should be kept under a slight positive pressure. MS (23)

Progress in Steel Plants During the Year 1930. (Fortschritte im Stahlwerksbetrieb im Jahre 1930.) H. ILLIES. *Feuerungstechnik,* Vol. 19, Nov. 15, 1931; pages 177-179; *Rolling Mill Journal,* Vol. 5, June 1931, pages 433-435.

The improvement of the efficiency of open hearth furnaces during 1930 is reviewed. Outputs have been increased due to improved melting conditions; the compromise between American and German melting practice by the Venturi or Danforth furnace end is shown. The wear and lifetime of furnace roofs, the Terni furnace end, the furnace of the Laclede Steel Co. (100 tons capacity) and the problem of automatic heat regulation are discussed. JN+EF (23)

Electrically Heated Core Drying Furnace. (Ein elektrisch beheizter Kerntrockenofen. E. FR. RUSS. *Elektrowärme,* Vol. 2, Apr. 1932, pages 86-88.

A continuous furnace of an elevator-like construction and with ventilation for carrying-off the moist air and gases is described. The height is 44 ft.; a maximum temperature of 300° C. is obtained with 450 kw. For an hourly output of 1600 kg. of cores, 180 kwh. are required. Ha (23)

Furnaces for Continuous Heating and Normalizing of Sheets. (Balkenherdöfen zum kontinuierlichen Wärmen und Normalglühen von Blechen.) *Stahl und Eisen,* Vol. 51, Dec. 31, 1931, pages 1620-1622.

The furnaces developed by the Surface Combustion Co., Toledo, Ohio, are described. GN (23)

Electricity as a Source of Heat in the Arc Furnace for Iron, Steel and Related Fields of Application. (Die Elektrizität als Wärmequelle für Eisen, Stahl und verwandte Anwendungsgebiete.) W. BRAUMUELLER. *Elektrowärme,* Vol. 2, Apr. 1932, pages 115-118.

The 3 principal types of electric arc furnaces are described, i.e. the Girod furnace where the current flows from one electrode through the charge to the other electrode, the Heroult furnace, where the arc is formed between the electrodes and charge, and the Stassano furnace where the arc burns only between the electrodes and the charge is heated by its radiation. The most commonly used type for the production of steel and gray Fe is the Heroult type; units up to 10,000 kw. are now built. The electrical conditions are discussed in detail; the efficiency of the furnace has been increased by increased furnace voltage whereby the ratio of the total resistance to the useful resistance is improved. The methods of regulation of the arc in order to reduce current fluctuations and to improve the power factor are described. As the greatest losses are due to the leads from transformer to furnace the former is installed as close to the furnace as can be done for practical reasons. The general arrangement of such furnace installation is described with control and signal apparatus. Ha (23)

Resistors Embedded in Muffle Walls. Correspondence from E. W. EHN & H. DIERGARTEN. *Metal Progress,* Vol. 21, Apr. 1932, pages 69-70.

Electric annealing furnaces of improved design are replacing gas-fired equipment in German plants. Greater efficiency in continuous furnaces is secured by using fire clay muffles approximately 1" thick with the heating element embedded in the fire clay mass and by employing powdered kieselguhr as an insulating material. Thermal efficiencies of 80% are attained. WLC (23)

The Different Types of Electric Melting Furnaces in Steel Works. (Die verschiedenen elektrischen Schmelzofenarten im Eisenhüttenbetrieb.) R. GROSS. *Elektrowärme,* Vol. 2, Jan. 1932, pages 4-9.

Direct arc-furnaces, low frequency induction furnaces, high-frequency furnaces with induction heating, and reduction furnaces for ferro-alloys are described, their principles and pecularities explained, and tables of capacity and energy consumption given. Ha (23)

The Use of Ammonia Gas as a Source of Hydrogen for the Production of Reducing Atmospheres. J. R. GORDON. *Canadian Chemistry & Metallurgy,* Vol. 16, Apr. 1932, page 101.

NH_3 is synthesized from N and H in the presence of a catalyst at 400°-500° C. and pressures of 100-200 atmospheres. The reverse action proceeds rapidly in the presence of an Fe catalyst at 600° C. under normal pressure. A set-up consists of a silica tube filled with steel wool and heated to 600° C. in an ordinary combustion furnace. The equipment is easily set up and can be assembled from standard parts. WHB (23)

Blast-Furnace Engineering. With Particular Reference to the Dagenham Furnace of the Ford Motor Co., Ltd., and the Pretoria Furnace of the South African Iron and Steel Corporation, Ltd. W. R. BROWN. *Iron & Steel Institute, Advance Copy* No. 5, May 1932, 20 pages; *Metallurgia,* Vol. 6, May 1932, pages 1-5; *Iron & Coal Trades Review,* Vol. 124, May 6, 1932, pages 741-747, 756; May 20, 1932, pages 823-833.

After a brief discussion of the factors that must be considered in designing a blast-furnace plant, 2 plants are described. Both of the furnaces are designed to produce 500 tons of iron/day. Materials for the Ford furnace are received by water and those for the African furnace by rail. Accessories for the furnaces are described. Plans and photographs of the plants are included. Ha + JLG (23)

Industrial Heating Processes. C. FOSTER CLARK. *American Gas Journal,* Vol. 136, May 1932, pages 25-27.

Gas fuel gives instant and positive control of the furnace atmosphere and temperature and thus prevents scale formation. New gas-operated systems of carburizing give a better case with the elimination of carburizing boxes and compounds. Continuous bright annealing in gas furnaces is now economical. Gas furnaces have been developed in which tools are hardened in a controllable atmosphere, protected from outside air and combustion gases by a muffle, sealed at the opening by an adjustable burning curtain of gas. Among the advantages listed for gas fuels over all other types are: Cleaner and easier to handle than solid or liquid fuels; adaptable to close control of temperature and furnace atmosphere; quicker to heat than electricity; flue gases produced create furnace pressures, carry heat by convection, and produce any desired furnace atmosphere; temperature can be controlled more closely than with any other source of heat. Data given for each of the following operations show gas fuel to be the most economical: Cyanide pots, stereotype metal melting, carburizing, annealing, bright annealing and japanning. CBJ (23)

Smoke Prevention in a Steel Works. H. CLIFFORD ARMSTRONG. *Fuel Economist,* Vol. 7, Apr. 1932, pages 267-269.

A review of steps taken to reduce the emission of black smoke in the Sheffield area, especially in connection with billet-heating furnaces and sheet-rolling mills is given. Gas was adopted as the heating medium in mill furnaces. A gas fired sheet-reheating furnace which gave good results in eliminating smoke is described. DTR (23)

New Type Electric Furnace Electrode. (Nouveau type d'electrodes pour fours electriques.) *Journal du Four Electrique,* Vol. 41, Feb. 1932, page 62.

French patent 707,729 describes hollow electrodes possessing many advantages. JDG (23)

Industrial Applications of Electrical Heating. (Applications Industrielles du Chauffage Electrique.) *L'Usine,* Vol. 41, Jan. 22, 1932, pages 31-37.

REFRACTORIES & FURNACE MATERIALS (24)

The Suitability of Various Refractory Materials for Lead Refining Furnaces. (Die Eignung verschiedener feuerfester Materialien für Bleiraffinieröfen.) E. R. THEWS. *Feuerfest-Ofenbau*, Vol. 7, June 1931, pages 84-86.

The peculiar difficulties due to the corroding effect of the molten Pb and the superheated Sb slag on the linings of Pb refining furnaces are anticipated. The more recent commercial refractories used as furnace construction materials are discussed i.e. mainly quartz, sillimanite, chromium, chromium ore, zirconium, carborundum, silundum, crystolon and andalusit bricks. Unfortunately most of these refractories are too expensive. A comparison between burnt fire clay and magnesite bricks is made and the superiority of the burnt fire clay bricks due to their technological properties and low initial costs is stated. Some practical suggestions are furnished for cutting down extreme corrosive action of the Sb-slag. EF (24)

Refractory Materials. Fireclay Bricks. COLIN PRESSWOOD. *Metallurgia*, Vol. 5, Mar. 1932, pages 169-170, 172.

A discussion of various bricks and their properties. 14 references. JLG (24)

Investigation of the Influence of Slag on Refractory Bricks by Means of a New Testing Method. (Untersuchung des Einflusses von Schlacke auf feuerfeste Steine an Hand eines neuen Prüfverfahrens.) J. SCHAEFER & F. BAUHAUER. *Feuerfest-Ofenbau*, Vol. 7, Mar. 1931, pages 33-36.

Critically discusses the testing method of Mellor & Emery (*Transactions Ceramic Society*, Vol. 18, 1918/19, page 230) in which the dust is blown in a downward direction on horizontal bricks. The writers designed a small testing furnace in which slag is blown in an atomized state on the vertical refractory brick. Tests are carried out in which silica and magnesite bricks were exposed to the scorification of metallurgical slags. The testing results are collected in 4 tables and the authors establish a method of quantitative determination of the degree of scorification. EF (24)

Mining and Processing Fireclay. GEORGE J. YOUNG. *Engineering & Mining Journal*, Vol. 132, Apr. 1932, pages 215-218.

An illustrated description of the plant and the processing of fireclay at the Stockton Fire Brick Co., San Francisco, Cal. WHB (24)

Some Properties of Chrome Spinel. C. W. PARMELEE & ABDE ALLY. *Journal American Ceramic Society*, Vol. 15, Apr. 1932, pages 213-225.

Expansion curves of five chrome ores, covering a wide range of chemical composition from different localities, were found to be more or less uniform in the temperature range 25-1250° C. There is a marked increase in expansion in all samples above 1000° C. The non-magnetic nature of the ores suggests the presence of Fe in the ferrous form. Ores high in both Cr_2O_3 and SiO_2 tended to give high expansions. There is a decrease in the mean expansion values in the interval 25-1250° C. with the decrease in the initial specific gravities; the decrease, however, is not proportionate. There is an increase in the specific gravity of the ore when heated, but the increase is not proportional to the temperature rise. The purity of the ore cannot be definitely ascertained by its specific gravity determination or by X-ray examination. Lattice dimensions were inversely proportional to the Al_2O_3 content of the ores. The length of the edge of the unit cube varied from 8.283 $\pm$ 0.001 to 8.179 $\pm$ 0.002 A. U. Theoretical densities computed by extending a method generally applicable to alloys of continuous substitutional types had a maximum difference of 1.3% between the theoretical and the actual values in the case of ores with complete analyses available and an optimum difference of 5.93% where some of the undetermined constitutents were estimated. WAT (24)

Notes on Kiln Markings of Fireclay Brick. S. M. KIER. (General Refractories Co.). *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1139-1140.

Paper read before the American Refractories Institute, Oct. 9, 1931. Major cause of kiln marking is the deformation or compression of a portion of the brick, resulting from the load which it has to carry in supporting the upper courses. Load tests were conducted, one being the standard test of 25 lb./in.² in which the temperature is raised in 4⅓ hr. to 2462° F. and then held for 1½ hrs. In the second test, the same temperature was reached in 91½ hrs. and maintained for 1½ hrs. Results showed that the brick began to deform at a lower temperature in the long-time test and that, in general, the total deformation was greater than in the short-time test. Another set of experiments using the two rates of heating was made. The load, however, was not applied until the final temperature was reached. It was found that the long-time test gave a much lower final deformation. Second type of marking results from "secondary expansion" which occurs at comparatively low temperatures. Laboratory tests show that a very light load of about 0.5 lb./in.² will prevent this expansion. Suggests that, in order to produce the best brick, overcoming the troubles of kiln marking, and insuring their maximum life in service, they should be fired at a sufficiently slow rate and at a temperature which is sufficient to prevent shrinkage. MS (24)

Zirconium Bricks for Metallurgical Furnaces. (Zirkonsteine für metallurgische Öfen.) W. HERMANN. *Feuerfest-Ofenbau*, Vol. 7, Oct. 1931, pages 146-147.

Points out how to meet the drawbacks of Zr-material, i.e. the large initial costs and the considerable brittleness. The initial materials and their natural occurrence are reviewed. The advantages as high melting point (3000° C.) low coefficient of thermal expansion (8.4 x 10^{-7}), low heat conductivity, large resistance to temperature breaks and to chemical attacks are emphasized. The favorable compression strength, only surpassed by carborundum, is however accompanied by great brittleness. Little information on the commercial production methods of ZrO material is known and only the method of H. C. Meyer is given. EF (24)

Modern Developments in Furnace Refractories. *World Power*, Vol. 17, Jan. 1932, page 58.

Recent developments, by the Babcock and Wilcox Co., in the manufacture of refractories from kaolinic materials are of interest as showing the possibilities of this class of material. A refractory kaolin is used for making the company's No. 80 firebrick and other products. This material is calcined to completely eliminate its shrinkage and to develop the maximum amount of mullite. It is then sized, bonded, molded and burned to produce a recrystallized structure and insure uniformity of size, texture and quality, without warping or kiln marking. The analysis of the firebrick is as follows, silica 51.96%, iron oxide 0.57%, titanium oxide 1.73%, aluminum oxide 45.38%, calcium oxide 0.10%, magnesium oxide 0.22%, sulphur trioxide 0.04%. Service results appear to indicate that the brick has a very high resistance to rapid changes in temperature. Shrinkage and expansion curves show that there is no permanent volume change up to 2900° F. and only a slight shrinkage change up to 3000° F. The average coefficient of expansion is 0.00000242, or considerably less than the figures for other representative firebricks. The point at which permanent volume change begins is about 2900° F. instead of the usual 2300° F. A further important feature is the load-bearing capacity of the firebrick at high temperatures. Refractory cements with the same base as the No. 80 firebrick have been developed to meet various furnace conditions. The melting point of this cement is 3180° F. and its vitrification point 2200° F. It forms a strong bond at all temperatures and may be used up to within 25° of its melting point. WAT (24)

A Comparison of the Rates of Flow of Water and of Air Through Refractory Materials. F. H. CLEWS, E. O. MILLS & A. T. GREEN. *Institution of Gas Engineers, 22nd Report of the Refractory Materials Joint Sub-Committee, Copyright Communication* No. 39, Sept. 25, 1931, pages 23-25; *British Refractories Research Association Bulletin*, 25, 1931, pages 48-54.

The order of H_2O penetrability of refractories of permeability to H_2O is identical and very nearly the same as permeability to air. AHE (24)

A Contribution to the Investigation of the Heat Conductivity of Refractory Materials with Particular Consideration of Magnesite Bricks. (Beitrag zur Untersuchung der Wärmeleitvermögens feuerfester Steine unter besonderer Berücksichtigung der Magnesitsteine.) M. BOETTICHER. *Mitteilungen aus dem Forschungsinstitut der Vereinigte Stahlwerke Akt.-ges, Dortmund*, Vol. 2, No. 10, 1932, pages 235-248.

Specific gravity, volumetric weight, porosity, gas permeability, linear expansion, average heat expansion coefficient, softening at high temperatures under load were measured and the data, together with the chemical analysis are tabulated. X-ray pictures of the structure are also given. The principal results are that heating magnesite bricks at a temperature considerably above their burning temperature changes specific weight and grain size of the brick; these changes have a direct bearing on the heat conductivity which increases with increased specific gravity and grain size. The change of the heat conductivity is, however, small. A relation between heat conductivity and gas permeability and porosity could not be stated. 25 references. Ha (24)

The Permeability of Refractory Materials to Gases. Part I. Experiments with Fire Clay and Silica Products at Ordinary Temperatures. Part II. Experiments with Fire Clay and Silica Products at Temperatures up to 500° C. F. H. CLEWS & A. T. GREEN. *Institution of Gas Engineers, 22nd Report of the Refractory Materials Joint Sub-Committee, Copyright Communication* No. 39, Sept. 1931, pages 5-15; Sept. 1931, pages 16-23; *British Refractories Research Association Bulletin* 25, 1931, pages 24-47; *Bulletin* 26, 1931, pages 44-56.

The true and apparent porosity and minimum and maximum permeability of representative samples of silica and fire clay products were determined. There is no definite relationship between percentage porosity and permeability coefficients. Data on permeability in 3 different directions show that the permeability coefficient is much less perpendicular to the 9 x 4½ inch face than in either of the other 2 directions. Part II. A method is described by which the permeability to N of 5 fire clay, 5 silica and 1 siliceous material has been measured directly at temperatures up to 500° C. As the temperature increases, permeability decreases in a manner almost independent of the nature of the material and the value of its permeability coefficient at ordinary temperatures, For a temperature increase from 10° to 500° C. the permeability is reduced to almost ½ its value for fire clay products and to slightly less than this for silica. The increase in gas viscosity with rise in temperature accounts almost quantitatively for the decrease in permeability, but small variations in the results for the different products suggest the dependence to a minor degree on a further factor related to the pore structure of the material. The inversion between 100° and 250° C. in the low specific gravity forms of silica may account for the divergence of the results between the fire clay and silica products. AHE (24)

The Heat Conductivity of Ceramic Refractory Materials. Calculations of Heat Conductivity from the Constituents. (Die Wärmeleitfähigkeit keramischer feuerfester Stoffe. Ihre Berechnung aus der Wärmeleitfähigkeit der Bestandteile.) A. EUCKEN. *Forschungsheft* 353, Supplement to *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 3, Mar.-Apr. 1932, 16 pages; *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, May 1, 1932, page 243.

The experiment was divided into 3 parts: (1) including a general point of view and formulae for an approximate (relative) calculation of the temperature curve of the possible heat conductivity; (2) including exact methods for calculating the heat conductivity of binary aggregates and ternary aggregates with high and low glass content; (3) special calculations of the heat conductivity of certain ceramic materials. GASES IN METALS (25)

The Influence of the More Common Elements in Inhibiting Needles in Nitrogen-Rich Steels and Arc Welds. L. W. Schuster. *Iron & Steel Institute, Advance Copy* No. 13, May 1932, 27 pages.

Welded layers, and nitrided, carburized and decarburized specimens of varying composition were examined to determine the effectiveness of several elements in preventing the formation of nitride needles. It was necessary to cool the specimens very slowly, for nitride needles separated from some samples on extremely slow cooling but not on somewhat more rapid cooling. C did not inhibit the formation of the needles. About 1% Mn or 1.1% Si tended to inhibit their formation. S and P apparently had no effect. Between 2 and 2.5% Ni or 0.9% Cr prevented the formation of the needles. A high Mn content welding rod did not prevent N absorption. 7 references. JLG (25)

Effect of Nitrogen on Steel. A Practical Consideration as Applied to Commercial Open-Hearth Steel. Frank W. Scott. *Industrial & Engineering Chemistry,* Vol. 23, Sept. 1931, pages 1036-1051.

48 references. The effect of N on steel has been magnified by nitrifying regular 8-ton ingots and comparing the physical properties of this steel to the regular product. N has been found to have 4 times the effect of the same amount of P. An increase of 0.01 % in N content was sufficient to cause a marked difference in the physical properties of the steel. The coefficient of effect increased with the increase of carbon. An equation has been derived whereby the effect of an increase of nitrogen on the elongation of the steel may be calculated quite accurately. Also the equation may be used to indicate the benefits to be derived by using a denitrifying agent. The average amount of N found in open-hearth steel was 0.0045 %. Such an amount was not found to be seriously detrimental to the quality of the steel. MEH (25)

Chemical and Electrical Phenomena on Gas-Charged Metallic Surfaces. (Ueber chemische und elektrische Vorgänge an gasbeladenen Metalloberflächen.) R. Suhrmann. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 203, Dec. 30, 1931, pages 235-244.

The property of some metals to adsorb certain gases on their surface to an extraordinary degree is discussed; the formula of Van der Waals does not hold good for all metals and gases; the author assumes therefore that electrostatic causes have to be used for an explanation. Metals are distinguished from other elements of the periodic system by the fact that they emit glow electrons at high temperatures, and photoelectrons on radiation with short-wave light. The formula of Richardson permits the calculation of this emission. If an atom whose valency electrons are only loosely bound together is brought into contact with the surface of a metal with great electron affinity the valency electron is pulled into the metal surface and the electron affinity is hereby partly saturated; this is explained by the Einstein formula connecting the quantum energy with the electron velocity. Polarization and chemical border phenomena are closely related with adsorption. 12 references. Ha (25)

Blowholes and Porosity in Non-Ferrous Castings. N. P. Allen. *Foundry Trade Journal,* Vol. 46, Apr. 14, 1932, pages 229-230.

A report of a paper presented at a joint meeting of the Institute of British Foundrymen and British Institute of Metals, in which the causes of cavities in non-ferrous castings were dealt with in some detail. The questions of gas solubility, of water vapor and hydrogen contamination, are discussed and attention is directed to methods of deoxidizing metals and alloys. OWE (25)

The Determination of Gases in Metals, Especially Oxygen in Iron and Steel, According to the Vacuum Extraction Method.) H. Diergarten & E. Piwowarsky. *Mitteilungen aus dem Giesserei-Institut der technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 9 pages.

A Review of Work on Gases in Copper. O. W. Ellis (Ontario Research Foundation). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 478, Feb. 1932, 28 pages.

Bibliography of 30 references. A critical review of the work done on this subject. Considers results of plant observations as well as laboratory tests. JLG (25)

The Degassing of Metals. F. J. Norton & A. L. Marshall (General Electric Co.). *American Institute Mining & Metallurgical Engineers, Preprint,* Feb. 1932, 28 pages.

The rate of extraction of gas from Mo used as electrodes in vacuum tubes was determined. To remove the gas completely it is necessary to heat to 1760° C. in a vacuum in the neighborhood of 0.001 micron for a time dependent on the thickness of the sheet. The gases extracted were CO and N. The N is the more difficult to remove. Some work was also done on W, Ni and C. The equipment used and the calculations are discussed in detail. Some tests on the absorption of gases are also described. 8 references. JLG (25)

The Oxide Contents of Aluminum and Methods for Its Determination. (Ueber den Oxydgehalt des Aluminiums und Methoden zu seiner Bestimmung.) H. Loewenstein. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 199, No. 1/2, July 8, 1931, pages 48-56.

The content of oxide in Al can amount, especially in old Al, to several percent. As difficulties in casting of Al have been ascribed to presence of oxide the author investigates the two methods of Jander and Hahn and finds that by testing Al in containers of pure alumina the oxide content can be determined exactly; presence of silica falsifies the results. The amount of oxide present in Al does not depend upon its origin but is only due to surface oxidation. Ha (25)

The Thermo-Forces of Palladium, Iron and Palladium-Silver Alloys Charged with Hydrogen. (Ueber die thermokräfte von mit Wasserstoff beladenem Palladium, Eisen und Palladium-Silberlegierungen.) Rolf Nuebel. *Annalen der Physik,* Ser. 5, Vol. 9, 1931, No. 7, pages 826-838.

The thermo-force of these materials is strongly influenced by the amount of hydrogen in the metal. The alloy Pd-Ag has a pronounced maximum of the thermo-force at 40% Ag. Test methods and results are described. Ha (25)

Gases in Metals. (Gase in Metallen.) THEWS. *Die Metallbörse,* Vol. 21, June 20, 1931, pages 1157-1158. 11 references.

The more recent investigations on the occurence of gases in metals are reviewed with emphasis on H and O_2, N_2, CO, CO_2, SO_2. EF (25)

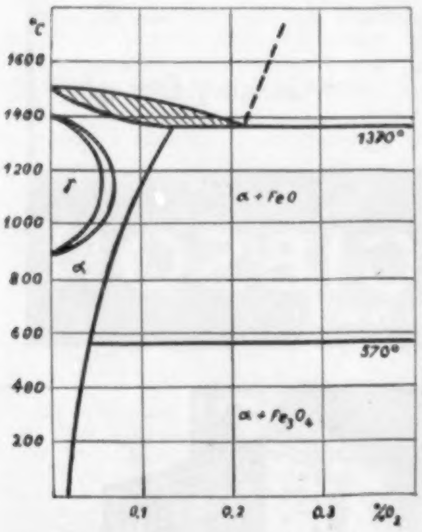
Influence of Gases on Metals and Influence of Melting in Vacuo. WILHELM ROHN (Heraeus Vacuumschmelze, A. G.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 470, Feb. 1932, 8 pages.

Briefly discusses the occurrence and effects of gases in metals. Gases can be removed by melting in vacuo. To do this it is necessary to actually melt in vacuo and not simply to allow the molten material to solidify in vacuo. Impact tests have proved that vacuum melting improves physical properties. Even with 4-ton furnaces the increase in cost due to vacuum melting is about 10c per lb. The technique has, however, developed to a point where it is possible to start such furnaces with a molten charge, and the additional cost in this case should be between 1 and 2c per lb. JLG (25)

Controlled Atmospheres for Annealing and Welding. J. F. T. BERLINER. *Metal Progress,* Vol. 21, Apr. 1932, pages 39-43.

Inert and reducing atmospheres for annealing, scale removing, flame cutting, welding and brazing may be economically supplied by a device now being manufactured by the DuPont Ammonia Corp. for the catalytic dissociation of liquid ammonia. The dissociator, which is only 3 feet high and 14" in diameter is capable of supplying 400 ft.^{3} of gas (75% H_2, 25% N_2) per hour with very little attention from the operator. The cost is 0.155c/ft.^{3} with ammonia at 6c/lb. If an atmosphere of pure N_2 is desired the hydrogen may be burned and removed as H_2O by a special attachment. One 100 lb. container of liquid NH_3 yields a volume of very pure N_2 equivalent to the contents of 39 standard cylinders of compressed N_2. The cost of the apparatus is of the order of $600. WLC (25)

Oxygen in Iron. (Tlen w zelazie.) I. FESZCZENKO-CZOPIWSKI & S. ORZECHOWSKI. *Prace Badawcze PWU,* 1931, No. 2, pages 5-38.



49 references. As a result of investigations, and of observations, a diagram Fe-FeO was constructed. The area of γ-Fe is limited to 0.07% O_2 (a number determined by Inouye). Oxygen dissolves in Fe at room temperature up to 0.02%, when at temperature of solidus the solubility increases to 0.13% O_2. About 0.21% O_2 can be dissolved in liquid Fe at 1370° C. The fact that such a low melting point of Fe in presence of O has not been observed, is the objection to this diagram. However this diagram can explain the abnormal grain growth during heat treatment of steel containing O as the O drives out the C from the solid solution. The same explanation can be given to the anomalies in C cementation, and to troostitic spots in quenched steels. A steel not sufficiently deoxidized contains grains of γ-Fe beside the grains of α-Fe. The difference in dilatation of these both kinds of grain during allotropic transformation causes the brittleness of steel. ZJ (25)

Gases Evolved from Molten Metal. HENRY D. HIBBARD. *Iron Age,* Vol. 129, Mar. 10, 1932, pages 611-612.

Gases evolved from molten metal in open-hearth furnace are chiefly those causing the "boil" and those which the boiling gases carry off. Composition of boiling gases changes, as does their volume, as the heat progresses from melting down to finishing. Cooling of molten metal in mold lessens its power to hold the gases in solution. Killed steel containing usually about 0.25% Si evolves no bubbles of gas in mold. Partly killed steel evolves gas in mold in quantity inversely proportional to the degree of killing. Segregation seems to be largely an effect of escaping gas bubbles in mold which, by keeping the liquid in motion, make it wash off and mix with itself the rejected impure matter from crystallizing steel. Dead steel emits no gas and segregation in it is comparatively slight. VSP (25)

Gases in Pipe Cavity and in Gas Holes in Ingots. HENRY D. HIBBARD. *Iron Age,* Vol. 129, Mar. 24, 1932, page 715, adv. page 20.

There are 3 common kinds of gas holes in commercial steels: (1) Sinkholes, (2) intermediate holes, and (3) central holes. In properly made rimmed steel the gas holes are so located that they do little or no harm. Pipe gases are in part ammonia but in varying proportions. All 3 common kinds of gas holes are exemplified in ordinary rimming steel. Intermediate holes, which occur only in rimming steel are in a zone extending all around and the whole length of ingot inside the sinkholes, with a secondary layer of sound metal between them. Abnormal steels may have gas holes not like any of the 3 common kinds mentioned. Some ingots may be sound inside though bad on the surface. VSP (25)

Degasifying of Light Metals. *Chemical Age,* Vol. 24, Mar. 1931, pages 208-210; *Metallbörse,* Vol. 21, Apr. 4, 1931, page 631.

Investigations of different people have shown that gas may be partially removed from molten light metal alloys by introducing chlorine gas. Different chlorides and tetrachlorides remove the gas without having a grain refining effect. Titanium and stannic tetrachloride are the only ones which act as grain refiners as well as removing the gas. The tetrachlorides of Si, Sn and C and Al chloride, Fe chloride and acetylene tetrachloride degasify Al-Si alloys. (25)

Press for Tube Pieces. (Abdruckpresse für Rohrformstücke.) H. SONDERMANN. *Stahl und Eisen,* Vol. 51, Sept. 10, 1931, pages 1151-1152.

Illustrated description of a new press for hydraulically testing tubes. GN (26)

Modern Shop Methods for Testing, with Particular Reference to Optical Automatic Precision Instruments. (Neuzeitliche Werkstattmessverfahren unter besonderer Berücksichtigung optischmechanischer Präzisioninstrumente.) O. P. VAN STEEWEN. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 7, Sept. 10, 1931, pages 177-180; Nov. 10, 1931, pages 193-197.

Describes gages, the Hirth-minimeter, optometers, microscopes, pitchometers, cog wheel testing apparatus, etc. etc. MAB (26)

Test for Smoothness of Machined Surfaces. F. A. FIRESTONE, F. M. DURBIN & E. J. ABBOT. *Metal Progress,* Vol. 21, Apr. 1932, pages 57-59.

The authors describe a device for amplifying and recording the irregularities on the surface of machined pieces by means of the angular movement of a mirror attached to a pointer tracing the surface. This movement is recorded photographically. WLC (26)

Optical Investigation of the Inner Walls of Hollow Bodies. (Optische Untersuchung der Innenwand von Hohlkörpern.) O. DAHNE. *Zeitschrift für Schweisstechnik,* Vol. 21, Jan. 1931, pages 12-15.

The novel optical outfit aims at the inspection of rolled or drawn tubes, hollow shafts, steel bottles, etc., with the object of detecting cracks, crevices, pores, corroded and pitted spots or other kinds of defects. The Zeiss "Rohrwandseher" permits examination of pipes of 18-400 mm. inside diameter and of any length practically reasonable. The magnification of the electrically illuminated spot depends on the diameter of the hollow body as follows:

inside diameter	magnification
40 mm.	4.4
80 mm.	2.9
100 mm.	1.8
200 mm.	0.9
400 mm.	0.5

Supplementary equipment permits the inspection of the bottom of cylindrical bodies and to take snapshots of the interior parts of cylinders. EF (26)

Reo Cuts Inspection Costs by Using New-Type Gages. *Iron Age,* Vol. 129, Jan. 14, 1932, pages 179-180.

Describes a few of the gages used, including the new electric type. For inspecting outside diameter of piston pins the new visual gage is used. The gage is actuated by a shadow which is magnified by passing through two condensing lenses. In the anvil of the gage is a strip of tungsten carbide, while on the end of a spindle is mounted a diamond. For measuring big end of connecting rods an inside indicator gage is used. This provides a three-point contact in the bore. A similar gage is used for small end of connecting rods. Crankshaft main bearings are checked by a Zeiss passometer caliper gage. The outside diameter of valve tappets is measured by a Sheffield electric indicator gage. For checking thread profiles and matching odd shaped surfaces a J. & L. Hartness comparator is used. VSP (26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Calcium Improves Iron and Lead. C. L. MANTELL & CHARLES HARDY. *Metal Progress,* Vol. 21, Apr. 1932, pages 60-65.

A review of the properties, uses and manufacture of Ca. The metal is becoming increasingly important as a deoxidizer for cast Fe, steel and Cu. Cast Fe deoxidized with Ca has lower S and graphitic C and a higher tensile strength and impact value than Fe deoxidized by ordinary methods. Pb-Ca-Ba alloys, 2% Ba and 1% Ca, are finding some application as bearing metals. Pb-Ca alloys possessing higher fatigue resistance tensile strength and hardness than Pb-Sb alloys are coming into extensive use as sheathing material for electrical cables. Ca is used as a reagent for the removal of Bi during the purification of Pb. WLC (27)

Bismuth, Essential to Fusible Alloys, Has Additional Possibilities. W. C. SMITH. *Metal Progress,* Vol. 21, May 1932, pages 61-64.

Summarizes the properties, metallurgy, and recent applications of Bi. Ladle additions of 0.5% Bi to cast Fe increase fluidity to a substantial degree. Machinability and cleanness of castings is also promoted. Bi additions decrease tensile strength 70%. Analysis shows that only traces of Bi remain in the solidified Fe. WLC (27)

The Influence of Nickel on the Wear of Case-Hardened Steel. J. G. R. WOODVINE. *Carnegie Scholarship Memoirs, Iron & Steel Institute,* Vol. 20, 1931, pages 125-150,

30 references. The author reports a study of the comparative wear resistance of plain C, 1% Ni, 3% Ni and 5% Ni case-hardening steels which shows that with proper lubrication there is little to choose between the 4 steels though in service the 1% Ni steel is somewhat inferior. With dry rolling friction and abrasion by emery the plain C and 3% Ni steels are equal while the 1% and 5% Ni steels follow in descending order. With dry sliding friction the plain C steel is best followed by the 5%, 3% and 1% Ni steels in descending order. WLC (27)

Influence of Various Additions on the Properties of Gray Cast Iron. (Einfluss verschiedener Sonderbestandteile auf die Eigenschaften des Graugusses.) *Die Röhrenindustrie,* Vol. 24, Feb. 26, 1931, pages 53-55.

The effect of Cu, Pb, Mg, Mo, Bi, B, Ca, Ce, Sb, As, Co, V, Zn, Zr, In, Ti, Wo on the properties of gray cast iron is reviewed. 36 references. EF (27)

The Effect of Phosphorus on Cast Iron. (Der Einfluss des Phosphors auf Eisen.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Mar. 6, 1932, pages 100-101.

Phosphorus in cast iron offers the following advantages: P bearing cast iron has a lower melting point and is thinly liquid so that the S of the cast iron can separate and the occluded gases can escape. GN (27)

The Use of Molybdenum in Alloy Steel Castings. W. H. Phillips. *Steel Founder,* Vol. 3, Mar.-Apr. 1932, pages 43-44, 57.

The addition of Mo to a steel imparts a deep hardening effect to heavy sections, ameliorates or even eliminates temper brittleness, widens the hardening range and simplifies heat treatment. A composition for a steel for exceptional service where shock and abrasion has to be met is given as C 0.25-0.35, Cr 0.7-0.9, Ni 1.75-2.25, Mo 0.15-0.25, Mn 0.7-0.9 It can be oil, water or air hardened and quenched from 1550° F. in water and drawn at 1000° to 1250° F. Several other compositions for various purposes are given. A comparison of a Cr-Ni steel with and without Mo at atmospheric pressure and 1000° F. gave the following results:

	without Mo		with Mo	
C	0.4		0.4	
Cr	0.8		0.8	
Ni	2.07		2.07	
Si	0.33		0.33	
S	0.011		0.011	
P	0.023		0.023	
Mo	....		0.29	
	70° F.	1000° F.	70° F.	1000° F.
Brinell hardness	232	.....	234	.....
Tensile strength	120,600	53,500	118,600	69,000
Yield Point	81,800	37,700	85,200	50,500
Elongation	21%	28%	20.1%	25.5%
Reduction	47%	56.5%	43.4%	71%
Loss in Heating From 70° to 1000° F.				
Tensile strength	63.7%		41.8%	
Yield Point	53.9%		40.7%	
Tempering temperature	920° F.		1290° F.

Impurities in Metals, Known and Unsuspected. Correspondence from A. Portevin. *Metal Progress,* Vol. 21, Mar. 1932, pages 69-70.

Notes on the effect of very small percentages of impurities in alloys. WLC (27)

The Behavior of Polonium in the Crystallization of Metals. (Ueber das Verhalten des Poloniums bei der Kristallisation von Metallen.) G. Tammann & A. v. Loewis of Menar. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 205, Apr. 8, 1932, pages 145-162.

While the distribution of impurities in metals and alloys is little known as metals are opaque the distribution of radioactive elements in metals can easily be detected even in minutest amounts, by electroscopic methods or photographically by the blackening action of the α rays on a plate. The production of Po alloys is described and the measurements showed that Po has only a very small tendency to form solid solutions. Saturated solid solutions contained only 2.31×10^{-11} to 5.28×10^{-10}% Po. Although Po is similar to Te it does not form the same compounds. Po is precipitated in the crystallization of Po-containing metals at temperatures which are considerably higher than the melting point of the polyeutectic. 13 references. Ha (27)

Excellent Properties Developed by Vanadium Alloy Steel Castings. Jerome Strauss & Geo. L. Norris. *Steel Founder,* Vol. 3, Mar.-Apr. 1932, pages 58-63.

Although V can serve as a deoxidizer it is not used for this purpose but added for its alloying qualities after deoxidation has been effected by cheaper elements. The percentage added is very small. A steel with only 0.05% V shows a much less marked dendritic segregation and a stronger, tougher and harder ferrite than V-free steels. These effects are shown in test results with several kinds of steel and in their micrographs; a number of castings are illustrated, especially large parts for locomotives, both steam and electric. Ha (27)

The Action of Cobalt in Carbon Steel under Consideration of technical alloyed Cobalt Steels, in Particular High Speed Tool Steel. (Ueber die Wirkung des Kobalts im Kohlenstoffstahl unter Berücksichtigung technischer legierter Kobaltstähle, insbesondere des Schnelldrehstahles.) E. Houdremont & H. Schrader. *Krupp'sche Monatshefte,* Vol. 13, Jan./Feb. 1932, pages 1-54.

It has been found that Co is a very good alloying material for tool steels, especially for saws. Also the magnetic properties are greatly improved. The investigation of the influence of Co on steel alloys is briefly summed up as follows; for the details of the exhaustive tests the paper must be referred to. Co increases in Fe-C alloys the α-γ transformation, with more than 40% Co the γ-range is widened. The addition of Co reduces the hardenability which causes less deformation and change of length when a Co steel is hardened. In annealed steel Co improves the strength at room and elevated temperatures. Co produces an increase in cutting capacity in high speed tool steel, and also in pure C steels. The addition of Co to these steels also increases the formation of austenite in hardening at high temperatures. An explanation of all phenomena is given by the structure of the steels which generally show an extremely uniform grain. A maximum of cutting capacity was found with 17% Co at 1280° C. hardening temperature. All tests are illustrated in curves and micrographs. Ha (27)

Tensile Properties of Cast Steel at Higher Temperatures with Special Regard to the Influence of Nickel. (Festigkeitseigenschaften von Stahlguss bei höhren Temperaturen unter besonderer Berücksichtigung des Einflusses von Nickel.) E. Piwowarsky & H. Nipper. *Mitteilungen aus dem Giesserei-Institut der technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 5 pages.

See *Metals & Alloys,* Vol. 1, Oct. 1930, page 788. (27)

Aluminum in Brass. (Aluminium in Messing.) *Zeitschrift für gesamte Giessereipraxis,* Vol. 53, Mar. 20, 1932, pages 126-128.

Al contents in brass of from .25-2% impart favorable properties inasmuch as Al favors the separation of the impurities, the elimination of oxygen, improvement of the fluidity and casting properties, increase of the tensile strength and elasticity, improvement of forging and rolling properties. The special precautions to be observed in casting Al brasses are mentioned. They should be cast as slowly as possible. GN (27)

The Effect of Cobalt on Carbon and High Speed Steel. (Die Wirkung des Kobalts auf Kohlenstoff-und Schnelldrehstahl.) Edward Houdremont & Hans Schrader. *Archiv für das Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 523-534.

Study was made of 4 different types of steel, C varying from 0.10% to 1.04%, and Co from 0.04% to 24.0%, melts being conducted in (1) acid high-frequency furnace; (2) basic open-hearth furnace; (3) crucible melting high speed tool steel; (4) molten ingot steel additions made to graphite crucible containing molten Co. Effect of Co was established from 5 different angles: (1) On behavior during heat treatment of C-steel; (2) on mechanical properties; (3) on case hardening; (4) increased decarbonization; (5) increase in cutting work and causes. The authors found that Fe-Co alloys do not have to belong absolutely to systems with an extended γ-range. Moreover, the γ-range is diminished with low Co content and corresponding rise of transformation temperature. Only with high amounts of Co, above 40%, is the γ-range enlarged. Transformation trend of γ- into α-Fe in C-steel is increased, corresponding to rise in transformation temperature through small Co-additions, and from this it may be derived that transformation temperatures are more difficult to lower by means of speeding up cooling rates. This results in increased critical rate of cooling, and harmful effect on hardness. The increased trend towards structure change expresses itself further in a decrease in amount of residual austenite in tempered steel and in an accelerated dissociation of austenite during annealing. The decrease in hardness is related to a magnification in hardness range. The slight overheating sensitiveness of less rapidly hardened Co-steel is confirmed by less grain enlargement during cementation. A relation between grain size during cementation and hardness was discovered which, developed by addition of an alloying element, corresponds to behavior of abnormal steels. A withdrawal of temper carbon by loosening causes a switch over to difficultly soluble, stable carbides, or graphite precipitation. Reduction of border C-content during cementation signifies a decreased affinity of γ-solid solution for C, corresponding to effect of an element, that is weaker carbide-forming than Fe. Graphite precipitation occurs in large quantity only when Co-steels are annealed far below their transformation points. Graphite forming below transformation may be eliminated by heating in γ-range followed by water quench or air cooling. This gives a high diffusion of C in cobaltous γ-solid solution, which may likewise be observed during cementation. A confirmation of small carbide stability and accelerated migration velocity of C in γ-Fe was obtained from the strongly decarbonizing Co-steels. Co in annealed steel improves its strength at atmospheric and elevated temperature. It is apparent that this change in strength properties, that indicates difficult particle separation, is related to decrease of lattice parameter and stronger atom combination with shorter space lattice plane distance. Improvement in work, obtained from high speed steel by Co addition, steadily increases on normal tempering at 1280° C. up to 17% Co. Similar improvement may be obtained with C-steels provided sufficient hardness is produced from the impaired physical property. Better cutting performance of Co alloy steels depends probably upon the increased hardness stability during annealing and higher hardness under heat. The improved hardness permanence depends on the rise in mechanical strength of the nucleus when the carbide conglomeration is retarded. Retarding of precipitation reaction and carbide conglomeration by Co changes the hardness slope during anneal to higher temperatures and longer annealing periods. This action is proved jointly with the heat hardness, which gives better cutting performance. The latter is produced by improved hardening through the effect of grain structure as well as by increased heat strength of the principal constituent, α-Fe. Included are 16 references, 2 tables 22 graphs, which well illustrate each important experiment. DTR (27)

The Influence of the Elements Silicon, Phosphorus, Aluminum, Nickel and Chromium on the Quasi-Isotropy and the Wall Thickness Sensitivity of Cast Iron. (Ueber den Einfluss der Elemente Silizium, Phosphor, Aluminium, Nickel und Chrom auf die Quasiisotropie und die Wandstärkenempfindlichkeit von Gusseisen.) E. Piwowarsky & E. Söhnchen. *Mitteilungen aus dem Giesserei-Institut der technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 4 pages.

See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 25. (27)

INSTRUMENTS & CONTROLLERS (28)

Measurement of the Electrical Conductance of Non-Metallic Pipe Coatings. E. R. SHEPARD. *American Gas Journal,* Vol. 136, June 1932, pages 22-26.

Measuring coating conductance is more difficult than measuring conductance of a metallic circuit or an electrolyte. The nature of conductance of coatings has been divided into 3 parts, namely, that due to large holes, that due to capillaries, and that due to inherent conductance. Conductance through capillaries is usually the chief component and any factor which changes or moves the electrolyte within the capillaries is likely to affect materially the total conductance of the coating. The conductance of a coating therefore is not a fixed or definite value but is indefinite and unstable. A complete description of the direct current test set for measuring coating conductances as well as a discussion of the technique of field measurements is given. CBJ (28)

The Effects of Heat Treatment on Fine Metallic Suspensions. N. N. ZIRBEL. *Physics,* Vol. 2, Mar. 1932, pages 134-138.

When a suspended system, such as is incorporated in a torsion balance or galvanometer, is supported by a fine wire the equilibrium position usually changes slowly for a long time after the load is applied. The equilibrium position of the system also changes with temperature. It has been found that both of these disturbing factors can be eliminated by a suitable heat treatment of the wire. Observations have been made on tungsten and platinum-iridium wires of sizes suitable for use in the Eötvos torsion balance. Although it is not pointed out in the paper the heat treatments involved were essentially annealing treatments, and most probably relieved the strains set up in the wires during fabrication. WAT (28)

The Value of Accurate Measurement. J. A. S. RITSON. *Iron & Coal Trades Review,* Vol. 124, Jan. 15, 1932, pages 50-81; Discussion, Feb. 19, page 325.

The great economical value of installation of exact measuring instruments, particularly for use in the generation, transmission and transformation of power is pointed out and examples given of losses accruing by faulty instruments or faulty arrangements of them. Ha (28)

International Standard of Electromotive Force. MARION EPPLEY. *Electrical Engineering,* Vol. 51, May 1932, pages 341-343.

Cd cells have proved to be convenient and reliable sources of standard e.m.f. Materials require careful chemical treatment. Hg_2SO_4 is particularly sensitive but when mixed with finely divided Hg can be prepared by electrolysis. Hg must be redistilled after an acid wash, and $CdSO_4$ should be of high quality. The use of the standard cell and the care and handling of it are briefly outlined. WHB (28)

Construction of Thermo-Elements by Electrodeposition. H. KERSTEN & R. SCHAFFERT. *Review of Scientific Instruments,* Vol. 3, Apr. 1932, pages 189-195.

The ordinary methods of thermocouple construction by joining 2 metals by soldering or welding are, in the method herein described, replaced by joining the metals by electrodeposition, making use of the fact that most metals plated on stainless steel may be peeled off easily. The manner of doing this is described in detail, the compositions of plating baths for Co, Ni, Cu, Cd, Fe, Ag and brass are given. This method can also readily be used for the plating of junctions in series, as for instance for bolometers or thermopiles. The advantages of this method are that it eliminates the difficulties of soldering together a number of small wires, that the mass of the junction can be reduced to a minimum, and especially, that the junction may be used at a higher temperature than soldered junctions. Ha (28)

The Duroscope. (Das Duroscope.) A. SCHWARZ. *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, pages 93-95.

A description of the "duroscope," a hardness tester. Curves for the conversion of duroscope hardness values into Brinell numbers are given for C-steels, Cr-Ni steels, Al and brass. RFM (28)

The Testing of Inner Walls of Highly Stressed Hollow Cylinders for Material Defects by Photography on Continuously Moving Film. (Die Prüfung der Dünenwandung hochbeanspruchter Hohlzylinder auf Materialfehler mit Hilfe des photographischen Aufnahmeverfahrens auf ständig bewegtem Filmband.) R. LOENHARDT. *Feinmechanik und Präzision,* Vol. 39, Sept. 1, 1931, pages 127-132.

The Askania Works, in coöperation with the AEG-Berlin, have developed a camera with an objective prism in a pipe of 3.25 m. length which can be introduced into the opening of tubes, pipes, hollow cylinders etc. for continuously photographing the inner surface. The theory of the apparatus, adjustment of speed in relation to the dimensions is explained and the construction and pictures taken illustrated. A special reproducing apparatus has been developed for this film. Ha (2

Control of Tunnel Kilns by Measuring Instruments. (Die Brandführung von Tunnelöfen nach Messgeräten.) W. LIESEGANG. *Berichte der deutchen keramischen Gesellschaft,* Vol. 13, Jan. 1932, pages 1-13.

The article gives a comprehensive survey on the value and the arrangement of temperature recorders for supervising tunnel kilns which are either coal fired, gas fired, or electrically heated. Extensive temperature measurements were carried on on all 3 of the above type kilns. Information is also given on the composition of the fuels, waste gases and the fuel consumption. GN (2

Use of Micropyrometer for High-Temperature Melting Point Investigations. G. R. FITTERER & M. B. ROYER. *Report of Investigations* No. 3151, *United States Bureau of Mines,* Mar. 1932, 18 pages.

A recording micropyrometer for the determination of the melting point of refractory oxides is described. It is accurate for determinations using stable compounds, eutectics and pure oxides. The accuracy is decreased with materials which have wide temperature ranges of solid-liquid immiscibility. 54 references. AHE (28)

Measurement and Regulation of Temperatures in Metallurgical Furnaces (Ueber Temperaturmessung und regelung in metallurgischen Oefen). F. KOFLER & G. SCHEFELS. *Stahl und Eisen,* Vol. 51, Dec. 10, 1931, pages 1529-1535.

After outlining the difficulties in continually measuring the temperatures of metallurgical furnaces, the authors show that these difficulties can be successfully overcome by optical measuring methods. Such an optical measuring method is described and illustrated in some examples as, for instance, open hearth furnaces, rolling mill furnaces, mixers, and rolling mills. The paper, furthermore, deals with automatic temperature recorders, describes the installation, working and recording. 2 references. See also *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 82. GN (28)

Use of the Tungsten-Molybdenum Thermocouple. D. BINNIE. *Journal Institute of Fuel,* Vol. 5, Feb. 1932, page 211; Abstract in *Electrical Review,* Vol. 109, Dec. 18, 1931, page 918.

As some precious metals have a very short useful life at high temperatures, the use of W and Mo for temperature measurement in the form of thermocouples was investigated. The junction was not easy to weld properly due to the high melting-points of the metals, but twisting one end of the wire tightly round the other gave satisfactory results. The thermo-electric curve is approximately parabolic in shape. The useful range of the couple is from 1200° C. upwards, the upper limit being the softening point of the furnace refractory material. At 1600° C., although the actual e.m.f. developed is small, the power is more than 8 microvolts per degree. Variability of the couple in use was tested by taking heating and cooling curves of a specimen of Armco iron, melting point 1530° C. Even after soaking at temperatures of over 1600° C. there was no alteration in the e.m.f. at the freezing-point of the iron, nor at the δ-γ transformation at 1403° C. Portion of the couple exposed to high temperatures in a H_2 atmosphere always became extremely brittle, particularly the W wire, and could not be subsequently cold worked. Use of the couple at high temperatures and particularly in oxidizing atmospheres, depends on an adequate protecting sheath. Highgrade porcelains are claimed to be impervious to gases up to 1750° C., and in the hands of a careful operator there seems to be no reason why accurate temperature measurements up to this point should not be obtained in combustion atmospheres. MS (28)

The Regulation of Temperatures in Industrial Furnaces. (Ueber die Regelung der Temperatur in industriellen Ofen). V. PASCHKIS. *Forschung auf dem Gebiete des Ingenieurwesens,* Ausgabe A., Vol. 2, Jan. 1931, pages 29-43; Feb. 1931, pages 57-61.

The characteristics and sensitivity of temperature regulation are discussed and exhibited in graphical form. WHB (28)

Automatic Heat Control of Open-Hearth Furnaces. (Selbsttätige warmetechnische Ueberwachung von Siemens-Martin-Oefen.) C. SCHWARZ. *Stahl und Eisen,* Vol. 52, June 2, 1932, pages 542-543.

Condensed summary and discussion from the literature, of automatic control and supervision of open-hearth furnaces. Use of instruments to get automatic control of fuel needs, air for combustion, draft and temperature measurements, waste gas analysis, gas pressure, heating value and composition of fuel, appears to be good modern practice. DTR (28)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Varnishing, Patina and Painting of Copper. (Vernissage, Patine et Peinture du Cuivre.) H. BREAU. *Cuivre et Laiton,* Vol. 5, Mar. 15, 1932, pages 113-115.

Usually Cu does not need to be covered with a protective coating; only if the brightness of new Cu is to be preserved or in order to harmonize decorative effects an artificial coloring is applied. In the former case, transparent cellulose varnishes are recommended. The green patina, natural or artificially provided is a good protection and besides gives fine and harmonizing effects with the surroundings for decorative purposes. For covering with a paint the Cu should not be polished too brightly as the paint will not adhere. Ha (32)

Serial Tests on White Paint Coatings in Regard to Atmospheric Stability and Rust Protection Power. I. Results from a Testing Period of 1½ years. (Bericht über die Ergebnisse einer Reihenuntersuchung von Weissfarben-Aussenanstrichen auf Wetterbeständigkeit und Rostschutzvermögen. I. Teil. Ergebnisse nach 1½ jähriger Versuchdauer.) E. MAASS & R. KEMPF. *Korrosion und Metallschutz,* Vol. 7, Oct. 1931, pages 237-242; Nov. 1931, pages 265-275.

Experiments were carried out which refer to 144 different coatings on mortar plaster, to 61 coatings on pine tree planks and to 102 coatings on iron plates. The original paper must be consulted for detailed information on the results which are presented in 6 illustrations each of which comprises 15-24 different samples (330 in total) and in tabular form which allows one to pick up at a glance the summary of the visual examination. (1) Confirmatory evidence was found in regard to the beneficial effect of non-oxidizing oil and of wood oil and of mixtures of both respectively. (2) Additions of benzin lacquer are detrimental, which effect however can be eliminated by the use of wood oil-non-oxidizing oil mixtures. (3) Oil saving lithopone never proved to be worse but usually better than purely precipitated material. (4) A marked superiority was noticed in the case of coatings containing Pb-chromate. The yellow discoloration, however, may prevent a wider adoption. EF (32)

Modern Methods of Enameling Cast Iron. J. H. D. BRADSHAW. *Foundry Trade Journal,* Vol. 46, Mar. 10, 1932, pages 162-165.

Paper read before the Birmingham branch of I.B.F. deals with the preparation of enamel, the calculation of enamels, the preparation of castings for enamelling, and, in conclusion, compares the results obtained by the dusting process and by the wet process. Some attention is devoted at the end of the paper to modern enamelling furnaces and to improvements that have been made in furnace appliances. OWE (32)

Manufacturers' Literature Reviews

534 **Nickel Alloy Steel Castings**—A pamphlet discussing the applications of nickel steel castings, the design of castings, the effect of alloying elements on cast steels and methods of adding alloys to steel has been prepared by the International Nickel Co., 67 Wall St., New York, N. Y. This is Bulletin No. 8-A of their Nickel Steel Data and Applications series. The 1932 issue of their Buyers' Guide for Nickel Alloy Steel Products is now available.

535 **KloiZenay**—The General Alloys Company, South Boston, Mass., have developed "KloiZenay," a colored glass poured on the casting so that the silica of the glass fuses with the metal.

536 **Alloy Steel Castings**—A recent pamphlet issued by the Lebanon Steel Foundry, Lebanon, Pa., is devoted to their alloy steel castings for high stresses and wear resistance and their stainless alloy steel castings for heat and corrosion resistance.

537 **Heat Treating**—A card recently sent out by the American Metal Treatment Co., Elizabeth, N. J., describes their nitriding, coloring and carburizing service as well as their "Machlet Ni-Carb-Case," a combination process of nitriding and carburizing.

538 **Metallizing**—Several leaflets sent out recently by the Metallizing Co., Los Angeles, Calif., describe their metal spray coating process and its applications.

539 **Truing Tool**—The Carboloy Co., Detroit, Mich., has sent out a leaflet showing the advantages of using the Carboloy truing tool for finish dressing a wide range of grinding wheels.

540 **Furnaces**—Bulletin No. 335 of the W. S. Rockwell Co., New York, N. Y., is devoted to their roller hearth furnaces, electric and fuel fired, for continuous heat treatment of metals.

541 **Valve Spring Wire**—A pocket-size booklet prepared by the Wickwire Spencer Steel Co., New York, N. Y., discusses the manufacture of their valve spring wire, its heat treatment and inspection. A table showing the tensile strength of various gages of the wire is included. The same company has prepared a booklet devoted to their welding wire.

542 **Die Blocks**—A leaflet sent out by the Heppenstall Co., Pittsburgh, Pa., discusses the manufacture of their die blocks. A pamphlet prepared by the same company is entitled "Serving Industry for Three Generations" and contains a short history of the company, describes their metallurgical service and facilities, and illustrates their products.

543 **Refractory Cements**—The different grades of their refractory cements are itemized in a booklet sent out by the Carborundum Co., Perth Amboy, N. J. Bulletin 6-A of the same company is devoted to their recuperative malleable iron air furnaces.

544 **Salt Baths for Heat Treating**—The J. W. Kelley Co., 13209 Athens Ave., Cleveland, Ohio, has sent out a leaflet giving the characteristics and applications of their various kinds of salt mixtures for use in heat treating.

545 **Protected-Arc Electrode**—The Hollup Corp., 3333 West 48th Place, Chicago, Ill., has sent out an announcement of their "Sureweld," a new protected-arc electrode.

546 **Jointing Material**—A leaflet distributed by the Cling-Surface Co., 1032 Niagara St., Buffalo, N. Y., describes the use of "Permac," a dry metallic powder for making flange and other joints without the use of packing.

547 **Weld it Well**—A booklet with this title has been issued recently by the Harnischfeger Corporation, Milwaukee, Wis. It is a fully illustrated book on the latest developments in welding practice and welder design, one double-page spread being a cross-section diagram of an arc welder. Bulletin HW-2.

548 **Cold Mills**—Bulletin P-202 of the United Engineering & Foundry Co., Pittsburgh, Pa., describes and illustrates their Precision cold mills, 2-high, 3-high, and 4-high, for the cold rolling of sheets and strips in all commercial metals, from heavy gages down to thinnest foils and flat wires.

549 **Eraydo**—The second edition of "Reference Data on Eraydo" has been issued by the Illinois Zinc Co., 332 So. Michigan Ave., Chicago, Ill. Eraydo is a zinc base alloy containing silver and copper to form a tough metal, said to be adapted to deep drawing, extruding and forging. The handbook describes it, gives its physical, chemical and electrical properties and illustrates many of its applications.

550 **Fluid Meters**—Bulletin No. 300 of the Bailey Meter Co., Cleveland, Ohio, describes and illustrates several types of meters and deals with their applications and methods of installation.

551 **Corrosion and Heat Resistant Steels**—Bulletin No. 30-9 of the Wehr Steel Co., Milwaukee, Wis., gives the physical analysis of the Wehr corrosion and heat resistant steels.

552 **Copper**—The Oct. 1st issue of the Bulletin of the Copper & Brass Research Association, 25 Broadway, New York, N. Y., pictures a number of interesting applications of copper and bronze.

553 **Furnace & Burner Equipment**—A recent bulletin of the Surface Combustion Corp., Toledo, Ohio, is devoted to their burner equipment, standard furnaces and continuous furnaces for annealing, carburizing, hardening, normalizing, nitriding and forging.

554 **Electric Furnaces**—Bulletin 4a of the Ajax Electrothermic Corp., Trenton, N. J., describes and illustrates their 3 kva. converter and furnace, by means of cross-section diagrams.

555 **Cast-Refract**—A pamphlet sent out by the Quigley Co., 56 West 45th St., New York, N. Y., describes their "Cast-Refract," a new type of refractory which can be cast or molded on the job and can be put under full heat within 24 hours. It is said to have excellent refractory properties up to 2600—2800° F.

556 **Pipe Bending**—Bulletin No. 50 of the A. M. Byers Co., Pittsburgh, Pa., is entitled "Principles and Practice of Bending Byers Genuine Wrought Iron Pipe." It describes what happens when pipe is bent and gives the minimum diameter of bends which can be made in various sizes of pipe.

557 **Arc Welders**—A leaflet sent out by the Universal Power Corp., 12367 Euclid Ave., Cleveland, Ohio, describes their portable road trailer type arc welders.

558 **Chemicals**—The winter price list of the Roessler & Hasslacher Chemical Co., New York, N. Y., has just been issued. Prices of chemicals for all industries are shown.

559 **Tool Steel**—A number of folders have been prepared by the Columbia Tool Steel Co., Cleveland, Ohio, each devoted to one of their tool steels. The applications, machining, forging, annealing, hardening, tempering and grinding of each steel are given.

560 **Controllers**—The Automatic Temperature Control Co., Inc., Philadelphia, Pa., has issued several leaflets describing their motor operated controllers, valves for fuel oil and relays.

561 **Steel Chain**—The Link-Belt Co., Chicago, Ill., has just issued an illustrated 144-page catalog on steel chains ranging in size from small chains having an ultimate strength of 950 lbs. to powerful chains of 1,500,000 lbs. strength.

562 **Electric Metal Heaters**—Several types of electric metal heaters are described in a folder sent out by the American Car & Foundry Co., New York, N. Y.

563 **Controller**—A circular sent out by Lucius Pitkin, Inc., New York, N. Y., discusses the Tour temperature controller and its points of superiority.

564 **Whiting Founder**—A late issue of this publication of the Whiting Corp., Harvey, Ill., contains articles entitled "Pulverized Coal in the Foundry," "Material Handling in the Foundry" and "Converter Steel."

565 **Seamless Tubing**—The use of seamless tubing for making parts is economical according to a folder issued by the National Tube Co., Pittsburgh, Pa.

566 **Springs**—An article entitled "Helical Torsion Springs" is the feature article in a recent issue of the *Mainspring*, a publication of the Wallace Barnes Co., Bristol, Conn.

567 **Price Card**—The Republic Steel Corporation, Youngstown, Ohio, has issued a new price card, effective Oct. 1, 1932, on Toncan Copper Molybdenum Iron Pipe. It embodies a simplified method of computing prices and shows slight changes in prices of various sizes of the pipe.

568 **Data on Heating-Unit Design**—The Hoskins Manufacturing Co., Detroit, Mich., has prepared a convenient card for determining the length of wire necessary in designing coiled units using Hoskins-Chromel "A."
